3. Professor Frazer further states that the part played by the intestinal bacteria in vitamin synthesis in human subjects is obscure. It has been shown that the human requirements of aneurin,[1] riboflavin,[6] and nicotinamide[2] are covered to a considerable extent by the production and release of these substances by the intestinal flora. These earlier investigations have been reviewed and discussed on several occasions.[7–10] It has been shown by simultaneous examination of the bacterial composition of the faeces and of the height of urinary nicotinamide methochloride elimination that the latter parallels the amount of *Bact. coli* in the faeces.[11] Of the most frequent inhabitants of the human intestines, *Bact. coli* produces, and *Proteus* and *Staphylococcus faecalis* consume, nicotinamide.[12]

4. The competition of nicotinamide-consuming and producing bacteria and other inhabitants of the intestinal tract as influencing the amount of nicotinamide available from this source for human requirements has been discussed in almost every

paper dealing with this subject. Consumption or production of nicotinamide by a mixed culture from the human caecum depends on the growth under anaerobic or aerobic conditions.[13] The fact stressed by Professor Frazer that in cases of sprue intestinal bacteria were found in the upmost part of the small intestine in a- or hypohydrochloric patients as being important in the development of the deficiency is irrelevant. Viable *Bact. coli* release only very little nicotinamide, while dead *Bact. coli* release this substance to a large extent.[12] In the highest part of the intestines most of the bacteria will be alive, while in the rectum a large proportion of the bacteria are dead, and nicotinamide is readily absorbed from the rectum.[14]—I am, etc.,

Manufacture of Cortisone

SIR,—After hearing a talk broadcast by the B.B.C. on the use of "compound E" in rheumatoid arthritis, in which the speaker mentioned that the bile from 40 carcasses of cattle was required to produce one daily dose of cortisone, it occurred to me that the present slow rate of production might be accelerated if it were possible to produce, by operation, biliary fistulae in suitable cattle. I can quite imagine that it might present a surgical problem of some magnitude, but, recalling the remarkable feats of surgery performed by physiologists such as Pavlov on animals, I can see no *prima facie* reason why it should not be feasible. Moreover, if cortisone proves to be indeed the answer to rheumatoid arthritis, it might be worth the trouble to arrange for the central collection of the bile that drains from the bile ducts of patients who have undergone choledochotomy, which in aggregate over the entire country must amount to many gallons daily.—I am, etc.,

Bedford. CECIL ALEXANDER.

The G.P. and E.C.T.

SIR,—E.C.T. again! Surely "this is where we came in." I can recall several previous discussions, in all of which I had the pleasure of joining. Dr. Donald M. O'Connor (October 29, p. 984), because of some relapses in his patients, would have us go back to "bromides, barbiturates, and chloral hydrate." Supposing a certain number do relapse, what is wrong with a second course of E.C.T., or even a third? Three courses can be given (average 6–10 treatments) in under three months, and a cure in this period compares favourably with 6–18 months of "bromides, barbiturates, and chloral"—not to speak of long periods in the latter treatment when one goes to sleep uneasily wondering whether the patient will stick it out or whether one will get a telephone message from a relative saying he failed to return "from a walk in the country."

As illustrating the value of E.C.T., may I quote my own experience here? Largely as the result of E.C.T., admissions to the hospital of which I am in charge (St. Luke's, Armagh) have quadrupled (approximately 90 per annum to 350) in the past five years. In spite of this our permanent population has risen very little. Had relapses been at all frequent or of serious nature we should have been swamped.

One point I will grant Dr. O'Connor: E.C.T. in out-patient practice is only about 60% as effective as when a patient agrees to enter hospital. This can easily be understood when it is appreciated that instead of continuous rest the patient must make his way home a few hours after treatment and perhaps have to tackle business or domestic problems with a mind showing marked temporary lapses of memory. Nevertheless, if the patient will not or cannot enter hospital it is an essential part of treatment for all anxiety and depressive conditions and should be given forthwith.

The long night of waiting in psychiatric practice is over and the dawn is here. Psychiatry, with E.C.T., insulin coma leucotomy, occupational and recreational therapy, suggestion persuasion, explanation, and understanding, is on the march and nothing will reverse the process and revive the days of "bromides, barbiturates, and chloral hydrate."—I am, etc.,

Armagh, Northern Ireland. ROBERT THOMPSON.

Health and the Soil

SIR,—In your issue of February 11, 1939, you were good enough to publish an article of mine entitled "Health and the Soil," which I prefaced with the modern danger of an excessive speed of knowledge at the periphery unaccompanied by a strengthening of knowledge at the centre. I supported this thesis with a saying of the great Goethe (who foresaw what we now see) in his *Wahlverwandschaften*: "Every evil shall be healed upon the spot, where it shows itself, and no one concerns himself about the place, where it really takes origin, whence it works its effects. For this reason it is difficult to take counsel."

Reflecting upon this divergency as affecting my own profession, I had for some years collected such notes as I could to restore a balance by concentrating on the central problem—namely, health—as revealed by the healthiest people I could find. Under the guidance of Sir Robert McCarrison I chose the Hunza of the Gilgit, of whom he wrote: "These people are unsurpassed by any Indian race in perfection of physique; they are long-lived, vigorous in youth and age, capable of great endurance, and enjoy a remarkable freedom from disease in general."

I embodied the results of my investigation in a book.[1] Briefly, the conclusion come to in this study was that in devising life nature devised health with it—the health of the soil, the health of the river and sea, the health of the plants, animals, and man as one interdependent whole—and that the key to the part that man should play was to preserve this interdependency by the rule of return, under which everything that had life in the soil should after death be restored to the soil as food for further life. This rule the Hunza followed: the dead leaf, the outworn cloth, the excreta, all were collected to form a compost for the soil that nourished further life.

This rule, it was found, was almost entirely neglected by the modern, city-dominated civilization. There were, of course, some who saw the terrible danger of this neglect. But as for official opinion and action, there is now the remarkable National Health Service. Its planning has been carried out with the utmost care and precision, such as evokes admiration and wonderment. So much so is this that its very creators, creatures of the periphery, praise themselves in no mean measure. "It offers a chance—and a challenge—to build the most efficient health service in the world, and one which as the years go by will add steadily to the nation's fitness, happiness, and working capacity." I almost quail before my own opinion of this fine boastfulness, but having reached threescore years and ten I cannot recede. It is this—that one doctor at least must make it public that this boast is "sheer bilge" in a scheme which takes no heed of the centre and throughout never mentions the soil.—I am, etc.,

London, S.W.1. G. T. WRENCH.

Sudden Obesity and Psychological Trauma

SIR,—I should like to record my appreciation to Drs. H. J. Shorvon and John S. Richardson for their excellent article (October 29, p. 951) on the above subject. No longer can we rely on the Shakespearean "lean and hungry look" as a steadfast sign of the anxiety state. The syndrome which has been discussed bears some resemblance to the acute exudative attacks of seborrhoeic dermatitis which are frequently psychogenic. It has been suggested by Barber[1] that these may be associated with

an increased secretion of the antidiuretic hormone from the posterior pituitary acting through the hypothalamic nuclei. In these cases there is evidence of cutaneous hydration, and they are favourably influenced by the promotion of diuresis. (As the obesity cases were kept on a full diet, their loss of weight was presumably associated with polyuria.)

In contrast to the severe psychiatric trauma in the authors' cases, acute seborrhoeic dermatitis may follow trivial emotional upsets, such as apparent "loss of face." It is to be remembered in this connexion that in Parkinsonism, where the principal lesions are in the substantia nigra, "seborrhoea" is a usual clinical feature.

It would be of interest to learn if these cases of obesity had an excessive secretion of sebum before treatment. In Case 2 mention is made of "an itching rash on the inside of her legs and pruritus ani."—I am, etc.,

London, W.1. IAN MARTIN-SCOTT.

Definition of Senility

SIR,—Considerable misunderstandings occur on account of the lack of definition of the words "senile" and "senility." This difficulty arises frequently for those in charge of homes for aged people. Some doctors will write a medical certificate saying that the old person suffers from "senility." This may mean that they are old and feeble. It may mean that they are mentally failing, and it may mean a complete break-up both physically and mentally. On the other hand, with the general public the two words are usually used in the sense of mental failure ranging from mild forgetfulness to senile dementia. They are, in fact, very loose terms describing various degrees of ageing, and it will be a matter of great convenience to all concerned if these terms can be more clearly defined.—I am, etc.,

London, N.6. M. N. HILL.

Pause for Refection

SIR,—To see writers on scientific subjects drawing to the full upon the rich treasure of the vocabulary of the English language is never other than a source of satisfaction. But words are in some sense tallies or counters, the legitimate use of which is subject to limitation. I am led to this reflection by the use of the verb "refect" by Professor A. C. Frazer in his paper entitled "A New Mechanism of Vitamin Deprivation" (October 1, p. 731). The *O.E.D.* defines "refect" used as a transitive verb as meaning "to refresh, especially with food or drink" and mentions that it fell out of use before 1700 and was revived in the nineteenth century, but has always been rare and is now somewhat rhetorical. According to this authority the late George Augustus Sala, eminently a rhetorical person, "remembered once refecting himself at a public dinner." But how and when is a rat "refected"?—I am, etc.,

Wolverhampton. S. C. DYKE.

Failed Forceps

SIR,—I read Professor F. J. Browne's article entitled "Failed Forceps" (October 29, p. 975) with great interest. I was, however, surprised and disappointed that he did not mention deep transverse arrest of the foetal head, which in my opinion is the commonest cause of arrest of the foetal head and therefore of failed forceps. It is noteworthy that none of the recent textbooks stresses this condition sufficiently, since new housemen are always surprised at the frequency.

Of our last 100 forceps deliveries, deep transverse arrest was found 40 times and a persistent occipito-posterior position twice only. If a pelvic application of the forceps is made the blades will slip off. Similarly I do not think it is sufficiently stressed in textbooks that the foetal head engages in the transverse diameter in approximately 40% of cases, and that deep transverse arrest is therefore only rarely due to an incompletely rotated occipito-posterior position.

Professor Browne recommends manual rotation by passing the hand into the vagina and the forefinger on to the anterior shoulder without dislodging the head. However, the latter is very liable to happen to a practitioner not well versed in this manœuvre, and he will find himself faced with a high free head to which he cannot or should not apply forceps unless he is able to press the head into the pelvis again. This explains why so many cases of "failed forceps" due to transverse arrest arrive in hospital with a high head, though the practitioner who failed to deliver the baby states that the scalp had been visible at the vulva before the attempt at delivery was made. It is therefore safer in the first instance to perform manual rotation of the head with one hand in the vagina and to rotate the anterior shoulder simultaneously with the outside hand. This almost invariably succeeds.—I am, etc.,

Leicester. W. P. HIRSCH.

The Acute Throat

SIR,—I have appreciated very much the comments made by the various critics of my article on the acute throat (October 15, p. 860). I am sure that it is only one of the functions of a refresher course to supply an up-to-date description of signs, symptoms, and treatment; the other, quite as important, is to make the reader take stock as it were and consider his own practice in the light of someone else's experience. If my forthright utterances have caused readers to ponder upon the value of different forms of treatment the article will have served a useful purpose.

I was of course aware that the sulphonamides were widely regarded as efficacious in tonsillitis. Nevertheless, it is necessary to be clear about what the sulphonamides are expected to do. I imagine I am not exaggerating if I say that of every 100 sore throats which are severe enough to make the patient seek medical advice at least 70 of them will subside, by means of the hosts' natural defences, within a matter of 24–48 hours. I am not satisfied from my own clinical observation that sulphonamides hasten this process. Further, one of my assistants, Dr. J. O. French, conducted a very carefully controlled investigation of the efficacy of sulphonamides in scarlet fever. She was unable to observe any beneficial effect upon the throat or upon the duration of pyrexia in those given sulphonamide compared with a group of patients (alternate cases) not so treated. When an infection shows a spontaneous tendency to rapid cure in a high proportion of cases one must be wary of making unqualified claims for a certain measure of treatment.

In the second place, the clinical diagnosis of streptococcal throat makes a further difficulty. From my own clinical observation, supported by adequate bacteriology, I am far from convinced that I can diagnose streptococcal tonsillitis on sight. In a fair proportion of apparently typical cases the flora obtained on a blood-agar plate is little different from the normal, and streptococci are disappointingly absent. As a rule, however, it is not difficult to recognize the effects of streptococcal invasion, and I feel that sulphonamide should be reserved for such cases. It was for this reason that I stressed the importance of examining glands, middle-ears, and sinuses.

Finally, I would like to plead for thoughtfulness in the use of all the different chemotherapeutic weapons. Coming to terms with the common pathogenic bacteria is, in this imperfect world, an essential part of growing up. The throat is by long experience well equipped to cope with most of the bacteria that meet it. The occasional mild tonsillitis may be no bad thing if, as a result, our immunity mechanisms are stimulated, for we may thereby be the better equipped to deal with later attacks. The unnecessary aborting of mild illness of no danger to the patient just for the saving of a few hours in the total duration of the infection should not too easily be regarded as a good thing. The experience of the clinician in the fever hospital leaves no doubt about the great increase in sensitization rashes. The experience of the clinician and of the pathologist leaves no doubt about the great increase in the occurrence of polyarteritis nodosa. I would be foolish to say that there was an absolute correlation between these facts and the known increase in the ingestion of sulphonamides, for of course there has been an increase in the ingestion of all kinds of chemicals in recent years. But such facts should make us pause before using sulphonamides routinely for trivial illnesses.—I am, etc.,

Glasgow. THOMAS ANDERSON.

POINTS FROM LETTERS

Congenital Pyloric Stenosis

Dr. C. V. PINK (London, S.E.3) writes: In their interesting memorandum Messrs. E. S. R. Hughes, H. A. D. Small, and J. W. F. Macky (October 1, p. 741) state that "the aetiology of congenital pyloric stenosis is quite obscure." So perhaps the following is worthy of notice, since it seems to indicate the direction in which we may have to look to find the cause of it. On return from a few days' holiday my late partner was told of a fully developed case of pyloric stenosis. The baby, 3 weeks old, had lost 12 oz. (340 g.) in three days, and the vomiting was definitely projectile. After interviewing the mother he told me that her attitude to the baby was all wrong and that he thought he had been able to help her put it right. The baby had no more symptoms from the time of interview. The trouble may have been that pregnancy was resented or used for purely personal ends. . . . The presence of a strong psychological factor in pregnancy is at least a possible explanation of the observations you published on the occurrence of pyloric stenosis in twins.

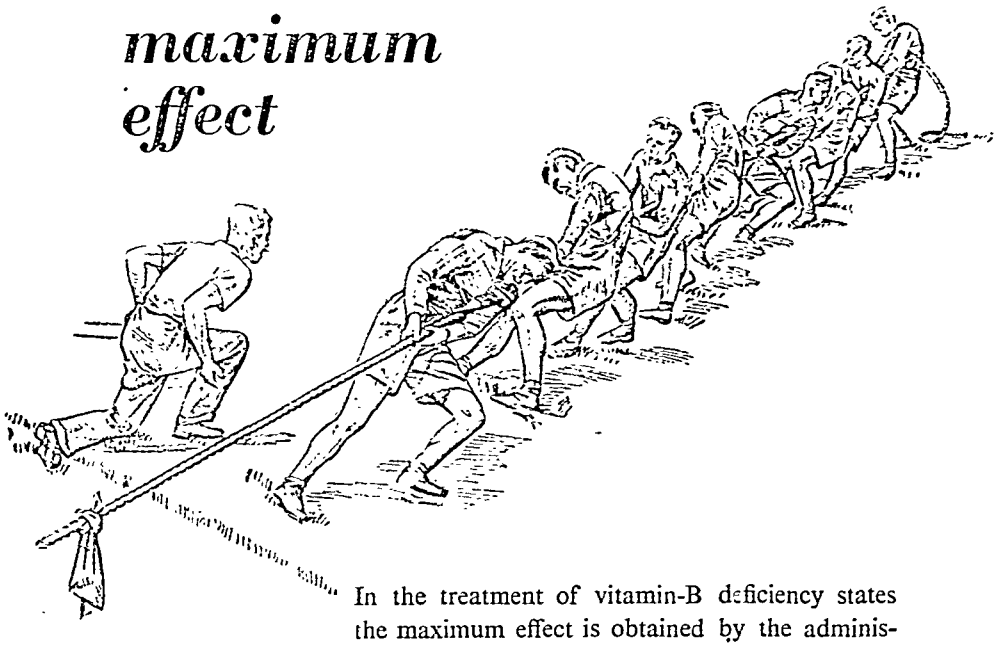
Spoons as a Measure

Dr. J. M. HAMILL (London, W.14) writes: It is generally considered that two tablespoonfuls equal approximately one fluid ounce, and I have a measuring glass on which the markings agree with this. I had, however, the curiosity to test whether the tablespoon markings on the measuring glass did correspond to actual tablespoons, and I found on trying several tablespoons in my possession that each when filled contains one ounce of liquid which when transferred to the measuring glass rose to the two tablespoonfuls mark. In other words my tablespoons measure just twice as much as the tablespoons marked on the glass measure and contain one ounce of liquid instead of the usually presumed half ounce. This has practical importance, because a physician may prescribe a dose of one tablespoon expecting this to be half an ounce, whereas with my tablespoons the patient would be getting one ounce.

Medical Administrators

Dr. JOHN SLEIGH (Saxmundham, Suffolk) writes: Mr. G. H. Colt (October 1, p. 756) regards the use of medical men purely as administrators and superintendents as a waste. He considers that medical men in their prime, superintending and inspecting hospitals and planning could be better employed working at medicine or surgery. It cannot be too often repeated that the treatment of illness and disease does nothing to reduce their incidence, and that the fall in the death rate during the last century has been due not to advances in treatment but to advances in environmental hygiene. . . . It is not unreasonable to presume that further improvements in the health of the people will be due in part to the concern of public health service administrators with those broader aspects of environmental hygiene to which most human ailments are due and with which in the past, being partly occupied with hospital administration, they have not had time to deal. As regards the question of the medical superintendents, it is at any rate noteworthy that the Central Consultants and Specialists Committee (Scotland) strongly favours the retention of the medical superintendent (*British Medical Journal Supplement*, 1949, 1, 270).

Open Sesame



Dr. H. J. HOYTE (Birmingham) writes: Dr. T. Anderson, in his instructive article (October 15, p. 860) entitled "The Acute Throat," refers to the difficulty of examining the throat of an uncooperative child. In my experience this is a real problem in the infant between 1 and 3 years old. Seated comfortably on his mother's lap, he has no objection to being thoroughly inspected—indeed he returns this with interest—but to let a strange man gaze into his interior would be, he feels, an unwarrantable intrusion into his own personal privacy. Yet the examination of the throat is so important, and it is almost equally important not to antagonize him (or her) by the use of force. The following little ruse takes only a few seconds of time and very often succeeds in unlocking the tight little lips. The child is seated on his mother's lap (or that of a nurse) in a good light. After a brief general inspection I turn to the mother and say, "Look, Mrs. ———, I'm going to peep into your mouth and then I want you to give a bit of a laugh." The mother opens her mouth, and I make a show of examining it without actually soiling my spatula; then she gives a laugh or murmurs, "Oh, how nice." If the father is at hand, or an elder brother or sister, I do the same with each of them and finally turn to the child, saying, "Now it's your turn," and in most cases the mouth springs open.

Obituary

Dr. JOSEPH EVERETT LA FRENAIS, of Runcorn, Cheshire, died suddenly on October 2 while on his way for a holiday in Scotland, with which country he had close associations. He was educated at Dollar Academy, and studied medicine at Edinburgh, qualifying in 1930. He was a house-surgeon at Hull Royal Infirmary, and later house-physician at Chester Royal Infirmary, where he first became acquainted with the county in which he finally settled in 1935. He soon became popular as a general practitioner, and was appointed to the visiting staff of Runcorn Hospital and also acted as police surgeon for the area. From the outbreak of the recent war he spent six years in the R.A.F., five of them in the Middle and Far East, including India, Burma, and China. He attained the rank of wing commander before he was invalided out with a disability which was subsequently to cut short his life at the early age of 44. Joseph La Frenais was the ideal type of practitioner. He possessed not only clinical ability of the highest order but a genial personality which with his friendliness and kindness attracted to him patients of all ages. Although a bachelor himself, he was especially fond of his young patients, who instinctively responded to him. In all aspects of his work, in all his endeavours on behalf of his patients, he never spared himself. On leaving the R.A.F. he resumed his practice—in partnership with his brother and later his brother-in-law. While fully aware of the implications of his disability, and of the necessity of having to suffer some restriction of his work, he faced the future with cheerfulness and courage. He was a freemason, a rotarian, and was associated with the Runcorn Squadron of the A.T.C. He always took a close interest in a number of sports, not only as a spectator, but as a player. He was a keen golfer, and at the time of his death was the popular captain of Runcorn Golf Club. His jovial and engaging personality brought him many friends, and, although ever proud of being a Scot, he occupied a prominent place in the town of his adoption. He was especially happy in his home and family life, and to his mother, brother, and sisters the sincere sympathy of his colleagues will be extended. The memory of the sterling qualities of Joseph Le Frenais will long be held not only by his patients and friends in Runcorn but by those of us who worked with him. To one who was his first assistant and enjoyed the hospitality of his home, the memory will be not only of an able clinician and unselfish chief but of a good friend.—E. W. T. E.

Dr. JOHN JOHNSTONE WILSON, of Anstruther, died on October 6 at the age of 82. He was born in Dunkeld, where his father was minister of the parish church, and educated at George Watson's College and Edinburgh University, graduating M.B., C.M. in 1889 and proceeding M.D. in 1894. He was a house-physician at Edinburgh Royal Infirmary with Dr. Affleck in the year following graduation. He came to Anstruther as an assistant in 1890. Despite the claims of an arduous and extensive practice, he found time for reading and study, as is shown by his taking the M.R.C.P.Ed. in 1922, 33 years after graduating. He was elected F.R.C.P.Ed. in 1925. Dr. Wilson was an enthusiastic member of the Fife Medical Association, holding office as president and also contributing several papers on medical subjects. He was an active member of the B.M.A. and was president of the Fife Branch in 1927–8. During his school and 'varsity days he was a noted rugby player. As an assistant he first lived in St. Monans—about four miles away—and walked to Anstruther daily, sometimes walking as much as 16 miles a day in all weathers. A son of the manse, he continued to take a deep interest in church matters and held office as an elder until his death. He was also a freemason and a past master of the local lodge. John Wilson had a long career as a general practitioner, yet he was something more. He showed that it was possible to combine reading and study with the management of a busy practice, and obtained high academic honours by examination at a time when most practising doctors consider they have left such ordeals far behind. He always put service

Towards maximum effect

In the treatment of vitamin-B deficiency states the maximum effect is obtained by the administration of a well balanced preparation containing the vitamin-B complex.

The characteristic symptoms which mild deficiency of this complex produces, including anorexia, loss of weight, constipation and depression, respond rapidly to the administration of Befolin Tablets.

When the diet is restricted or when the dietary intake does not meet an increased demand Befolin Tablets supply the ideal supplement.

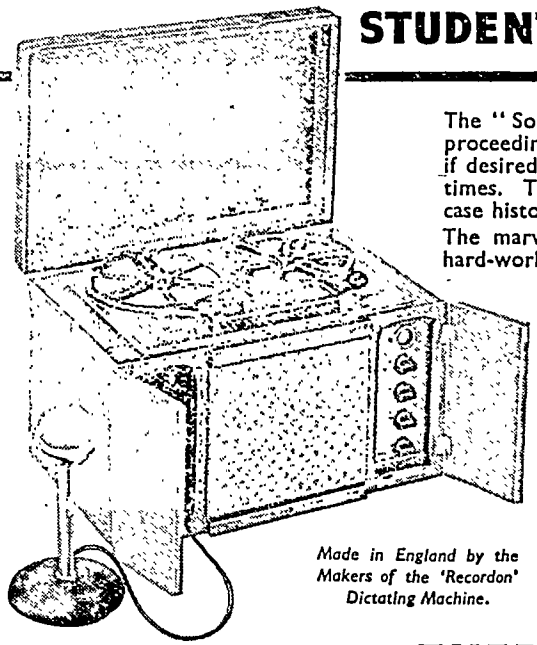
BEFOLIN

Each tablet contains:

Aneurine hydrochloride ..	1·0 mg.
Riboflavine	1·0 mg.
Nicotinamide	20·0 mg.
Folic Acid	1·7 mg.

Supplied in bottles of 25 and 100.

Literature on application.



ALLEN & HANBURYS LTD · LONDON · E·2

TELEPHONE: [illegible] TELEGRAMS: GREENBURYS, BETH, LONDON

For Recording

LECTURES, REPORTS CONFERENCES *and for* **STUDENT TRAINING Etc.**

The "Soundmirror" Magnetic Tape Recorder will make a verbatim recording of the proceedings. It gives a full half-hour's continuous recording with immediate play back if desired. The recordings are permanent and can be played an indefinite number of times. Think of the advantages of this for lectures and student training purposes, for case histories, conferences, discussions, and reports.

The marvel of magnetic recording/reproducing will prove an invaluable aid to the hard-worked medical profession.

Made in England by the Makers of the 'Recordon' Dictating Machine.

The "Soundmirror" requires no technical skill to operate it. It gives finger-tip recording . . . quick, simple and highly accurate. Old recordings can be erased and the magnetic tape used an indefinite number of times. Short recordings can be spliced —unwanted parts removed. Easy to handle—and easily stored. Protected by British and Foreign Patents and Patents Pending.

CALGITEX ALGINATES IN CASUALTY TREATMENT

Extensive and ragged lacerations require, as the crowning point of modern routine wound treatment, a dressing which prevents infection reaching the granulating wound, permits and advances uneventful healing and does not disrupt the wound on change of dressing (and thus start up oozing from the wound).

CALGITEX SOLUBLE AND ABSORBABLE WOUND DRESSING (in the form of gauze) answers all the above criteria. On application to the moist surface of the wound the layer of CALGITEX apposed to it will rapidly jellify, thus providing a plastic, impermeable film (which, however, allows water vapour to pass through, thus permitting "wound breathing") and become an integral part of granulation tissue. When the time comes to change or finally remove the wound dressing, soaking in tepid water will quickly remove excess CALGITEX alginate—there is no wound disruption, no pain, and no interference with natural wound-healing.

CALGITEX ALGINATE is compatible with all present antibiotics and chemotherapeutics (as long as no calcium salt is used as this would prevent alginate solubility).

CALGITEX EXTERNAL WOUND DRESSINGS are thus an important advance in the rational treatment of surface wounds.

CALGITEX ALGINATE gauze is obtainable in fast and slow absorption and solution grades. It is supplied in cartons of 6 glass phials each containing either one piece 4" × 7" or in ribbon form 1 yd. × 1 inch. **STERILIZED READY FOR USE.**

Manufactured by **MEDICAL ALGINATES LTD**

before self, and he was both doctor and friend to his patients. A man of character and resource, he set himself a very high standard of practice and was an example of the best type of country doctor, loved and respected by all with whom he came into contact. Always attentive to the interests of his patients, he looked upon their faults with a kindly and tolerant humour, giving freely without complaint arduous service to the community and finding in his work his chief reward. He leaves a widow and two sons, one of whom is a consultant physician with the Northern Regional Hospital Board.—A. A. M.

Dr. ROBERT SEVESTRE died at his home in Leicester on October 13 at the age of 81. Some months ago it was necessary for him to undergo an operation, from which he recovered sufficiently to enable him to get about again. Born in Calcutta, of Huguenot stock, he was brought to England in childhood, and was educated at Rugby, Trinity College, Cambridge, and St. Bartholomew's Hospital. He qualified in 1893, graduated M.B., B.Ch. a year later, and proceeded M.D. in 1896. Some two years later he was appointed honorary assistant physician to Leicester Royal Infirmary. Later he became honorary physician, and then, at the age of 60, he was elected honorary consulting physician. During the first world war he served in France in the R.A.M.C. with the rank of major, and was attached to a general hospital. Returning to this country, he was posted to the 5th Northern General Hospital, Leicester, where he met his wife, who was then on the nursing staff. He was the joint author of the section on "Wounds of the Chest" in the *Manual of War Surgery*. Mrs. Sevestre died in 1937, and their only son, a subaltern in the K.O.S.B., was killed in an accident in the Far East in 1943. Dr. Sevestre was appointed a justice of the peace for Leicester in 1929. He was a governor of the Wyggeston Hospital, chairman of the Pensions Committee, a trustee of Simons Charity, and an officer of the Order of St. John of Jerusalem. He was president of the Midland Branch of the B.M.A. in 1922–3, and represented his constituency at Annual Representative Meetings in 1904–6. He was also a member of the Leicester Medical Society. Dr. Sevestre was of a quiet and retiring disposition, but became widely known and highly thought of in the city to which he devoted a full life of medical service. A link with a previous generation of physicians has been severed at his passing. His work at the infirmary, to which he unselfishly devoted himself for so long a period, earned for him the gratitude of countless thousands of patients.—R. McD. C.

Dr. LIONEL DUDLEY WOODS died on October 23 at his home in the Isle of Man at the age of 63. He qualified in Dublin in 1907, finishing his course at the Meath Hospital, and he became house-surgeon at Noble's Hospital. He then entered general practice in the same district in which his father in an Irish jaunting car was so familiar a figure. In August, 1914, Dr. Woods went to Netley, and subsequently he served with distinction in Salonika. He was mentioned in dispatches twice and was awarded the O.B.E., the Serbian Order of St. Sava, and the Croix de Chevalier d'Honneur. A many-sided personality, Dr. Woods was a traditional family doctor, beloved by his patients and valued for his understanding of human nature. Soon after his return from the Army he was appointed honorary surgeon and radiologist to Noble's Hospital. In the earlier inter-war years he was most active in surgery, and especially noted for his management of difficult fractures. Later when rheumatism crippled his fingers he devoted himself more and more to radiology, and the present highly developed radiological and physiotherapy department at Noble's Hospital bears testimony to his constant endeavour to keep his department up to date. Dr. Woods was chairman of the War Pensions Board and of the medical division of recruiting. An active member of the B.M.A., he was president of the Isle of Man Branch in 1933–4. In 1926 he was made an officer of the Order of St. John of Jerusalem, and the present flourishing state of the brigade in the island is in great part due to his efforts. He ultimately became county surgeon. In the recent war he was medical officer to the first battalion of the Home Guard, and as the war progressed more work devolved on him. It was the strain of these years which took such a heavy toll of his strength and hastened his untimely death, a loss which his colleagues in the island feel acutely.—C. G. P.

Dr. FRANK GOWER BERGIN died at his home in Clifton, Bristol, on October 25, at the age of 70. A native of County Cork, Dr. Bergin qualified at Bristol in 1905. He was a house-physician and later a house-surgeon at the Bristol General Hospital before starting in practice in Clifton in 1908. From the earliest days he was interested in radiology, and in 1916 he joined the R.A.M.C. as a radiological specialist. He was serving on board H.M.S. *Britannic*, which was used as a hospital ship, when she was torpedoed and sunk off Malta. After his demobilization in 1919 he was appointed honorary radiologist to the Bristol General Hospital, and continued in this capacity until 1939, when, following the amalgamation of the Bristol hospitals, he was appointed director of the radiological department. In the very early days he possessed the only *x*-ray plant in the West Country, and often made long trips by ambulance with his portable apparatus in order to assist hospitals which had not at that time obtained *x*-ray equipment. Apart from his specialist practice, Dr. Bergin was for 37 years responsible for the medical care of the children and staff of Muller's Orphanage. At different times his father and his elder brother had served the same institution. He only relinquished this work last year on account of failing health. Dr. Bergin was for a number of years consultant radiologist to Clifton College, to the British Overseas Airways Corporation, and to Southmead Hospital, and he was a lecturer at Bristol University. He was also associated with the Bristol Dispensary, the Homoeopathic Hospital, and the Central Clinic. Dr. Bergin was a keen amateur photographer and gardener, and he always took the greatest interest in his many young friends, and particularly his own grandchildren. A deeply religious man, he was associated for over 40 years with the Clifton Bethesda. The sympathy of his colleagues, his former patients, and his many friends will be extended to his widow and his two sons, who are both members of the profession.

Dr. JOSEPH CORBETT MUIR, who was for many years medical superintendent of Whipps Cross Hospital, died suddenly on October 29 at his home in Gloucestershire. Dr. Muir studied at Cambridge and at Manchester, graduating M.B., B.Ch. in 1897, and proceeding M.D. in 1901. After holding resident appointments at the Manchester Royal Infirmary and at the Pendlebury Children's Hospital, he joined the staff of Plaistow Fever Hospital, working under the late Dr. Biernacki. In 1908 he was appointed medical superintendent of Whipps Cross Hospital, where he was to remain until 1932, except for a period from 1915–19 when as a captain in the R.A.M.C. he saw active service in Flanders and was for some time a prisoner of war in Germany. Whipps Cross Hospital had been open only for some five years when Dr. Muir joined the staff, and it may be said that its development into a busy, modern, and well-equipped general hospital is largely due to the advice which he tendered to the former West Ham board of guardians. A man of strong personality, he greatly improved the conditions of the patients and staff. He was a strict disciplinarian, but nevertheless he was very attentive in dealing with any problems concerning members of the hospital staff, many of whom will recall the help that he gave them. Dr. Muir was regarded by his professional colleagues as a practitioner of outstanding merit, and members of the consulting staff always valued his opinion on a difficult case. As a hospital administrator he was known throughout the country, and for a period held office as president of the Medical Superintendents' Society. Ill-health caused him to retire in 1932, and he had since been living at Box, in Gloucestershire. He closely identified himself with the life of the district and was a member of the Stroud Rural District Council. Although he was confined to his home, and was unable to visit the hospital for which he had done so much, nevertheless he was delighted to receive news of its progress and much appreciated visits from members of the staff if they happened to be in the neighbourhood. Although many of those who worked with Dr. Muir have left the hospital, there are still some who have personal recollections of his work.

while his reputation is known to all who profit by the standards which he set in the past. A keen sportsman, Dr. Muir was an accomplished tennis player and golfer. He played tennis for Essex and Gloucestershire, and he had a very low golf handicap. He was equally enthusiastic about rugby, and followed the fortunes of the Stroud Club. Dr. Muir is survived by his widow, to whom the sympathy of his colleagues and friends will be extended.—A. N. S.

Medico-Legal

INSANITY IN THE CRIMINAL LAW OF MALTA

BY

PAUL CASSAR, M.D., B.Sc., D.P.M.

Psychiatrist, Hospital for Mental Diseases, Malta

The plea of insanity raised by the defence in the recent Haigh trial (*Journal*, July 30, p. 286) demonstrated once again the difference between the medical and the legal view regarding the criminal responsibility of mentally disordered persons. This paper attempts to describe in brief how Maltese legislation deals with the question of the culpability of the insane offender and to outline the procedure followed by a Maltese court of law. It is suggested that similar legal provisions could be substituted in England for the present unsatisfactory tests of legal responsibility and methods of assessing the mental state of the accused.

A commission of five Maltese legal men was set up in 1831 to compile a criminal code and a code of criminal procedure for the Island of Malta and its Dependencies. The commissioners were instructed to base their work on the report drawn up in 1826 by a distinguished English judge, Sir J. Richardson, and upon the principles of the best foreign codes. The Neapolitan Code, promulgated in 1819 in the Kingdom of the Two Sicilies and based on the reformed French Code, was adopted as a model. In 1836 the first draft code of penal laws to be drawn up under British rule was published. After several revisions and a lengthy discussion in the Council of Government, the draft code was finally promulgated in 1854. Article 32 of this code stated that "no person is liable to punishment for an act done or omitted by him when he is of unsound mind or in a state of madness." Other articles dealt with the procedure to be adopted when the plea of insanity was raised and with the disposal of the insane criminal. Important amendments and additions to the original code were introduced in 1900, 1909, 1914, and 1935.

Present Provisions

The plea of insanity may be raised either during the inquiry (Court of Judicial Police as a Court of Criminal Instruction) or during the trial (H.M. Criminal Court).

During the Inquiry.—Article 34, para. (*a*), of the Criminal Code lays down that no one is liable to punishment if at the time of the act or omission complained of such person was insane. When, therefore, there are reasonable grounds for suspecting that the alleged offender was insane at the time of the commission or omission of the act, or at the time of the instruction, the court appoints one or more mental experts to examine the accused and report upon his state of mind. If they report that the accused was mentally ill at the time of the alleged offence, the court orders the transmission of the records of the inquiry to the Attorney-General. If the latter does not decide to contest the findings of the experts, the court decrees that the person in question be sent to the mental hospital, and it informs the Head of the Government of this step. The Head of the Government then issues such directions as he deems necessary for the care and custody of the insane person. The accused has the right of appeal against the court's decision. If the Attorney-General opposes the experts' opinion, he may direct the court to continue with the inquiry on the merits of the charge, or he may refer the matter to H.M. Criminal Court, where the issue of insanity is decided by a jury.

During the Trial.—In conformity with Article 34, it has been held that no one can be called to answer to a charge if at the time of the trial he is insane. Should the defence wish to raise the plea that the accused is insane at the time of the trial, it must do so during the preliminary proceedings following the reading of the indictment and before the answer of the accused party as to his being guilty or not. If the plea of insanity is raised by the defence after the preliminary stage, then it is dealt with together with the other pleas on the merits. The question of insanity at the time of the offence or at the time of the trial may also be raised by the court. In such a case, if the medical experts come to the conclusion that the accused was insane, and both the defence and the prosecution do not contest the experts' findings, then the court dispenses with further proceedings and orders the removal of the accused to the mental hospital.

Insanity at the time of the offence cannot be alleged after the jury has given its verdict, but, whenever the necessity arises from any fact or circumstance of fact expressly found by the jury, the plea of insanity, both at the time of the crime and during the trial, may be brought forward even after the jury's verdict on the alleged offence, provided that this plea is made before the delivery of the sentence of the court. The decision whether a person is insane or not is determined by the jury by a majority of votes. Following a verdict of insanity, the accused party is ordered by the court to be detained in the mental hospital. The board of the mental hospital is empowered to recommend the discharge of a criminal patient to His Excellency the Governor if the patient recovers or if he no longer requires further detention.

Medical Experts

Only the court has the right to appoint and to choose the medical experts. They are usually of an uneven number and they are given a specified time (which may be extended if necessary) within which to submit their report. They are given every facility to study the mental condition of the accused party. Thus, once the plea of insanity has been raised, the court orders the accused to be sent to the mental hospital "under observation for mental disorder." Here the psychiatrists will have every opportunity to study the accused man or woman. The experts swear to perform their duties faithfully and honestly. It has been recommended by the court that, whenever in the course of their inquiries the experts obtain information, the persons giving such information should be heard as witnesses and their information recorded in the form of statements. It has also been recommended that a regular *procès-verbal* of the interrogatory of the patient, when made by the experts, should be kept and filed with the report. The report of the psychiatrists is read publicly and they may be submitted to cross-examination under oath. Those persons who have given information to the experts are also examined like any other witness.

The court may allow the mental experts to obtain on oath all relevant information about the accused from witnesses residing outside its jurisdiction. It has been held "that it is the court's duty to see that every provision be made so that the experts may have at their disposal all such information as may enable them to give, in the interests of justice, a correct opinion." The court, the prosecution, the defence, and members of the jury have the right to ask for further elucidation from the experts on their report or on such other points as they may deem necessary in order to make the opinion of the experts clearer. The members of the jury are not bound to abide by the conclusions of the mental experts against their own conviction.

Comment

The superiority of Maltese law over English law on the subject of the culpability of the insane is obvious. In Malta there are no tests of legal responsibility in the case of mentally disordered persons arraigned before a court of law. Maltese legislators have not laid down any rules by which the distinction between sanity and insanity is to be drawn. They are aware that this demarcation line is a delicate one, and they leave it to the mental experts to decide when a man ceases to exercise control over his actions on account of mental illness. Maltese jurisprudence has likewise recognized the fact that, apart from psychosis and mental defect, such disorders of the personality as "adolescent instability" and "psychopathic

personality" may exonerate the accused from culpability. In Malta, therefore, it is enough for the psychiatrists to show that an accused person is mentally ill to exempt him from punishment. Of course the jury may not accept the psychiatrists' diagnosis of insanity, and they are free to judge the accused party to be sane in spite of the psychiatrists' opinion to the contrary. But the illogical situation of finding a person insane and at the same time legally responsible for his acts can never occur in a Maltese court of law.

Another advantage of Maltese procedure is in the calling of mental experts to assess the state of mind of the accused. The appointment of mental experts to examine the accused pertains to the court alone. It has been held that it is not only the right but also the duty of the judicial authority to ascertain the state of mind of the accused both at the time of commission or omission of the act complained of and at the time of the trial. To deny such a right to the judicial authority is to ignore one of the fundamental principles of criminal justice and to run the risk of convicting a non-responsible person.

The divergence of opinion that often arises in an English court of law about whether the accused is insane within the meaning of the law tends to create confusion in the minds of the jury. There may also be a tendency for the jury to look upon the mental experts of either the defence or the prosecution as biased or interested parties. Maltese legal provisions with regard to the choice of the mental experts cannot give rise to such perplexity in the minds of the jury. The psychiatrists are appointed by the court, and this ensures their absolute independence of both the defence and the prosecution. They are as independent as the judge himself. They are above any possible suspicion of bias either in favour of or against the accused, and, what is equally important, the public feels that justice is not only being done but is "manifestly and undoubtedly seen to be done."

Medical Notes in Parliament

NURSES BILL

The Nurses Bill was considered on report in the House of Commons on November 4. The committee stage was taken on October 28 (*Journal*, November 12, p. 1120).

Mr. BLENKINSOP moved and Mr. WALTER ELLIOT supported a new clause to impose penalties on persons who falsely represented themselves as being included in the list of nurses kept under Section 18 of the 1943 Act. The clause was added to the Bill.

Mr. HOWARD moved a new clause providing for the appointment of a training committee and setting out its powers. He pointed out that Parliament was setting up within the General Nursing Council one statutory committee to deal with finance and another to deal with mental nursing, but there was no statutory committee to consider improvements in the training of nurses. Mr. LINSTEAD, in seconding, said the General Nursing Council was ceasing to be an independent professional body and in half its activities was becoming a paying agent of the Treasury. Once it was partially integrated into the Government machine it was in danger of losing authority and independence.

Mr. BLENKINSOP said the control of training was the main function of the General Nursing Council, and it was clear that it would set up a committee, as it had done in the past, to look after this feature of its work. The Government had already gone as far as it ought in statutorily subdividing the General Nursing Council. Mr. SOMERVILLE HASTINGS believed that the clause would be undesirable. The object of the Bill was to separate the training of nurses from the administration of hospitals. Mr. HOWARD then withdrew the amendment.

Nurse-training Committees

On Clause 2 Mr. BLENKINSOP moved an amendment substituting "Area Nurse Training Committees" for "Standing Nurse Training Committees." This and other small amendments were approved.

On Clause 4 Mr. DIAMOND moved an amendment to ensure that the General Nursing Council should not be required to consider an estimate unless that estimate related to a hospital which had already been approved by the Council for the purpose of nurse training. Mr. BLENKINSOP said it was true that Clause 4 did not specifically refer to training which was in accordance with the Council's training rules, but Clause 6 clearly provided that the Council should defray all expenses which had been incurred by an Area Nurse Training Committee with the approval of the Council. It would be within the power of the Council to decline to approve any expenditure on training not in accordance with its rules.

Mr. LINSTEAD was perturbed at the suggestion that no finance would be forthcoming for nurse training except in respect of institutions already approved. That seemed to him to crystallize and sterilize everything. He hoped the Minister would say a few words on how experimental training schemes, while they were being built up to the stage justifying approval, were to be financed. Mr. BLENKINSOP said the Bill left the General Nursing Council full discretion to deal with expenditure in the building up of training schools to the required standard.

Mr. WALTER ELLIOT said the grading up of hospitals and the standards of teaching institutions had been points around which arguments had gone on for years, particularly in regard to the grading up of local government institutions to the point of becoming teaching institutions. An institution anxious to reach the standard might believe it could do so, but the General Nursing Council might think it could not. In those circumstances a promising development might be stultified. There were many cases where advocates for a hospital becoming a training school had great difficulty in persuading the powers that be that the hospital was fit to be recognized for training.

Mr. HASTINGS received an assurance from Mr. BLENKINSOP that if a regional hospital board decided to build a 200-bed hospital and to have a nurse-training school requiring a certain amount of building and equipment, the regional hospital board could apply for finances for this purpose. Mr. DIAMOND then withdrew his amendment.

Mr. HOWARD moved an amendment to make it clear that the Minister should not specify what type of equipment or activity was desirable for the purpose of training nurses. He said it was for the professional body to specify and for the Minister to approve. Mr. LINSTEAD seconded this amendment.

Mr. BLENKINSOP suggested that the amendment would give to the General Nursing Council a responsibility for splitting up general expenditure which should not be the responsibility of that Council and must be the responsibility of the Minister. The amendment was negatived, and small amendments were accepted on Clauses 5, 6, and 7.

On Clause 8 Mr. BLENKINSOP moved an amendment authorizing the nomination to the finance committee by the Minister of not more than two persons other than members of the Council, after consultation with the Council. He said the Government felt that such appointments would be valuable to both sides. The House accepted the amendment.

Mr. BLENKINSOP further moved as an amendment to the First Schedule that some of the first members appointed to the Council should hold office for a term of three years. He said this would provide more overlapping of the periods of office of the different members of the Council. Minor amendments were made in the Second Schedule and the report stage ended.

Third Reading

The third reading followed immediately. Mr. BLENKINSOP said the House was anxious to give every encouragement to the General Nursing Council because of the value to the Health Service which would come from the further improvements in nurse training which the Bill would effect.

Sir HUGH LUCAS-TOOTH said the Opposition had apprehensions that difficulties would arise in the working of the Bill. He feared the Government had over-simplified the position, perhaps because they had in mind what had been done in the training of doctors. Ministers were disposed to think that it would be possible to set up some kindred organization which would work as easily and as quickly. The organization connected with the medical schools had grown up over a very long time and it would be difficult to introduce a similar organization quickly for training nurses. He feared there would be a number of errors before the country secured a satisfactory system.

Colonel LIPTON said both teaching hospitals and municipal hospitals, as they used to be called, would gain from the co-ordination that was likely to be brought about by the Bill. He welcomed the assurance given earlier by Mr. Blenkinsop that the General Nursing Council was not likely to make demands upon the teaching hospitals which would diminish their high standards. He hoped that neither regional boards nor hospital governors would deter any ward sister or any others in the lower ranks of the nursing profession from endeavouring to get elected to the General Nursing Council.

The Bill was then read a third time without a division.

National Federation of Hospital Officers

Sir JOHN MELLOR on October 25 drew attention to the refusal of the Minister of Health to negotiate with the National Federation of Hospital Officers. He said the Federation had been formed and registered as a trade union in 1948. Its constitution prescribed that only administrative, clerical, professional, and technical workers in hospital should be eligible for membership and that its activities were to be limited to the interests of hospitals services and hospitals officers. It further provided that these activities should be strictly non-political. At present in the administrative and clerical field the Federation had approximately 3,500 members out of its total membership of about 6,500. In July, 1948, the Federation wrote to the secretary of the staff side of the administrative and clerical functional council under the Whitley scheme in the National Health Service applying for seats on the functional council. That application was not approved.

The Federation then appealed to the Minister and asked him to grant it the right to negotiate directly with him if it was not given seats on the functional council. The Minister's attitude was that the composition of the staff side was a matter for the staff side itself. Later the Minister wrote that he would not be warranted in entering into separate discussions with the Federation on matters within the scope of the Whitley Council. The Minister had in fact created a closed shop with no mandate from anyone in the Service except the members of certain bodies which he had invited to form a staff side. Sir John said the National Federation had a larger membership than any other body which had a seat on the Whitley Council. There were about 40,000 hospital officers in the administrative and clerical categories, and the bodies which had been established on the staff side represented only about 8,000 out of this number.

Mr. BURDEN asked Mr. Bevan not to accede to the request of Sir John Mellor. An overwhelming majority of the hospital staffs were already members of existing trade unions. These unions and professional organizations had acted as negotiating bodies before the National Health Service Act, 1946, was passed. The National Federation of Hospital Officers did not exist when the Minister invited the staff side organizations to agree to the setting up of the new functional councils. In accordance with Whitley practice person in question could obtain admission to the Whitley [illegible] the Head of the Gh the consent of the existing staff [illegible] the Government then issues such from normal procedure if he [illegible] care and custody of the insane sponsors of the Federation [illegible] appeal against the court's decision. [illegible] ex-voluntary hospi- [illegible] another opinion, he may direct the court [illegible] trade union [illegible] merits of the charge, or he may [illegible] of the [illegible] Court, where the issue of insanity is decided [illegible] [illegible] nformity with Article 34, it has been held [illegible] to answer to a charge if at the time of [illegible]

Sir JOHN MELLOR said these men were not opposed to trade unionism but were opposed to political trade unionism, and the constitution of the Federation reflected that opposition.

Mr. HAYDN DAVIES said Sir John Mellor had not rendered a service to the hospital administration by raising this matter. His endeavour was to make things more difficult for those who had to administer the teaching hospitals. It was sheer snobbery for persons to say that they could not be represented on the staff side of the Whitley Council through their trade union. Before the mushroom growth of the Federation there had been appropriate trade unions which could have taken in all the professional men.

Dr. H. B. MORGAN said that the union of which he as a medical man was a member, the Confederation of Health Service Employees, had more officers as members than had the Federation. The Federation had been formed from a source which had had opportunities in previous years to get representation on bodies connected with hospital matters and had suddenly realized after the passing of the National Health Service Act that the voluntary hospitals were part of the national health system. The Federation was a new union of doubtful strength. He doubted whether it would last long. Many trade unions still had no representation. Some were too small and some were not sectionalized enough. The health section of the Transport and General Workers Union was definitely sectionalized and discussed only its own problems. The Federation should wait its turn and ask for representation when the Act had consolidated itself. He thought that Sir John Mellor did not know the difficulties which had been encountered in consolidating the status of doctors and of nurses in the Service and of adjusting one side to another. Those behind the scenes were doing their best to get a smooth passage for the Act, which would take at least five years to come to full fruition.

Mr. BLENKINSOP, replying to the debate, regretted that this discussion would make the position on the Whitley Council more difficult. If it were to be suggested that the Minister as employer should have a right to settle the form of staff side representation, that would have a most disastrous effect on the health services. It would be difficult for the Whitley machinery to work smoothly if separate negotiations were going on with another body. The Ministry had not closed the door to future direct negotiations should it be satisfied that by denying them a large proportion of the workers in this field would be ruled out of representation. The Ministry did not feel that a membership of 3,000 out of some 22,000 workers was sufficient to warrant its interference with the Whitley Council and the danger of breaking the Whitley Council arrangements by opening direct negotiations. He accepted that membership of the Federation was growing and said that the Ministry would have to review the matter later. Before the Ministry opened negotiations it must also be satisfied that the Federation was becoming established as a permanent body. It had only been in existence for a short time.

Second Opinions by R.M.O.s

Mr. DOUGLAS HOUGHTON on November 1 asked the Minister of National Insurance what decisions were reached by regional medical officers in the 202,188 cases referred to them for a second medical opinion in the twelve months ended September 30, 1949, and in the 75,189 referred to them in the previous twelve months.

Mr. JAMES GRIFFITHS, in reply, circulated the following table with the particulars asked for expressed as percentages:

	Cases submitted to Regional Medical Officer	
	Year ended September 30, 1949	*Year ended September 30, 1948*
Accepted as incapable without examination after consultation with claimant's doctor, or found incapable of work on examination	48	41
Incapable of normal occupation but not incapable of alternative work	4	5
Not incapable of work	16	13
Failed to attend examination or submitted evidence of recovery before examination	32	41

Heparin-Boots

(INJECTION OF HEPARIN B.P.)

the natural anticoagulant

HEPARIN is *the granular substance present in the mast cells in the walls of the vascular and reticulo-endothelial systems.*

HEPARIN is a powerful, non-toxic anticoagulant without cumulative effects, which can be safely administered in large doses

It is the only safe anticoagulant for use outside hospital practice, and has been used extensively for the prophylaxis and treatment of thrombosis.

Injection of Heparin-Boots is a pyrogen-free sterile preparation derived from high purity HEPARIN of not less than 100 units per mgm. Available in 5 ml. rubber-capped Vials (1,000 and 5,000 I.U. per ml.).

Illustrated leaflet on application

A series of trifles, individually insignificant, can be a source of anxiety and annoyance to someone already overworked and tired. Such a condition of 'sub-health' is, unfortunately, only too common at the present time, and calls for the administration of a carefully-formulated tonic. Ordinary tonics act by stimulating already depleted bodily reserves and their continued use can therefore produce no sustained benefit. 'Livogen' is a balanced composition of liquid extract of liver B.P., extract of yeast, vitamin B_1 and nicotinic acid. It supplements the reserves of the body and allows a natural return to full health and vitality to be made.

Mr. Griffiths added that the reports of regional medical officers did not constitute decisions on claims for benefit but were evidence which, along with the certificates rendered by the claimant's own doctor, would be taken into account by the statutory authorities in determining the claim.

No Names

Colonel ALAN DOWER on November 1 asked the Chancellor of the Exchequer to make known the names of the members of the Exchange Control Medical Advisory Committee who decided whether to approve or disapprove applications for urgent medical treatment abroad.

Mr. GLENVIL HALL replied that this could not be done. Sir Stafford Cripps had already said it would not be advisable to disclose the names of the members of the committee.

Morphine for Mountaineers

Mr. EDE, replying on November 3 to Squadron Leader FLEMING, said that, in consultation with the Minister of Health, he was considering whether it would be possible to make arrangements, subject to suitable safeguards, for the administration of morphine to injured climbers. He could not approve the arrangements which the Manchester surgeon, Mr. Wilson Hey (*Journal*, November 5, p. 1056), had operated since 1934 for mountain rescue squads to carry ampoules of morphine for the speedy treatment of injured climbers. He said he could not wink at defiance of the law for 15 years, but if Mr. Wilson Hey submitted another plan for the carrying of this drug he would consider it

Size of N.H.S. Lists

Mr. PLATTS-MILLS asked on November 3 for a list showing the numbers of general practitioners with 2,500, 3,000, 3,500, 4,000, and over 4,000 patients registered with them under the National Health scheme.

Mr. BEVAN said general statistics were not readily available, but inquiries had been made in a number of areas. Analysis of the information supplied by six areas, not necessarily typical of the whole country, showed that the following numbers and percentages of doctors on the medical lists of those areas fell into the different categories referred to by Mr. Platts Mills. In compiling the statistics doctors engaged in partnership had been assumed each to be responsible for the average of the number of persons on each partner's list. Doctors employing assistants had had their lists notionally reduced by 2,400 for each assistant. The number of doctors practising under the National Health Service in the six areas concerned was 2,429.

Size of List	Number of Doctors	Percentage of Total Number of Doctors
2,501 to 3,000	323	13·3%
3,001 to 3,500	277	11·4%
3,501 to 4,000	234	9·6%
Over 4,000	160	6·6%

Mr. Bevan added that as there was some element of inflation in executive council's registers, the figures in columns 2 and 3 might be higher than was actually the case. Executive councils were asked in November, 1948, to request doctors with lists in excess of 4,000 not to accept additional persons for inclusion in their lists, except relatives of persons already on their lists living in the same house, until their lists had been brought within the permitted limit. Executive councils generally acted on this request. Some had gone further and used their discretion to require doctors to take further steps to see that their lists were brought within the limit.

Convalescence and Holidays

Mr. PLATTS-MILLS pointed out on November 10 that when a child was sent away for convalescence by a hospital the cost was borne by the regional hospital board and there was no charge to the parents. But if the child was sent away by the local health authority for a recuperative holiday a standard charge was levied on the parents.

Mr. BEVAN replied that convalescence proper was part of the hospital service and was free. Facilities for holidays were one of the "extras" which local authorities could provide as a form of aftercare and for which they could make reasonable charges. He saw no reason to alter this.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In Congregation on October 29 the following medical degrees were conferred:

M.D.—F. W. Watkyn-Thomas (by proxy), H. Harris, B. G. Parsons-Smith, W. S. Haynes, R. V. Stone, C. C. Bryson, M. S. M. Palmer.

UNIVERSITY OF BIRMINGHAM

Professor George Haswell Wilson, M.D., resigned from the Chair of Pathology on September 30. He was elected Professor of Pathology in the University in 1922.

Professor S. Zuckerman, M.D., F.R.S., Director of the Department of Anatomy, has been appointed a member of the Agricultural Research Council.

Professor W. Melville Arnott, M.D., F.R.C.P.Ed., and Professor Zuckerman have been appointed to the University Research Committee as representatives of the Faculty of Medicine for the Session 1949–50.

Walter Thomas Smith, M.B., Ch.B., has been appointed Lecturer in Pathology and G. Cumming, B.Sc., Research Fellow in Medicine from October 1; and R. H. Cawley, B.Sc., Research Fellow in Medical Statistics from August 1.

Degree Day, 1950, will be held on Saturday, July 1, when there will be Congregations in the morning and in the afternoon.

The University Medical Officer's Department will in future be known as the University Health Service.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following were admitted to the Membership of the College on November 4: W. G. Keane, D. J. O'Callaghan, I. B. Patwari, O. P. D. Ryan.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following lectures will be delivered at the College (Lincoln's Inn Fields, London, W.C.): Tuesday, November 22, 3.45 p.m., Imperial Cancer Research Fund Lecture by Dr. James Craigie, "A Quantitative Approach to the Study of Transplantable Tumours"; Thursday, November 24, 5 p.m., Thomas Vicary Lecture by Sir Henry Wade, "The Barber Surgeons of Edinburgh"; Tuesday, November 29, 3.45 p.m., Imperial Cancer Research Fund Lecture by Dr. C. H. Andrewes, F.R.S., "The Virus Theory of Cancer in the Light of Recent Work"; Thursday, December 1, 5 p.m., Otolaryngology Lecture by Professor Geoffrey Jefferson, F.R.S.; "Intracranial Abscess"; Thursday, December 8, 3.45 p.m., Arnott Demonstration by Mr. R. J. Last, "The Knee Joint"; Tuesday, December 20, 3.45 p.m., Arnott Demonstration by Mr. Last, "The Larynx."

The lectures are open to those attending courses at the College and to all other medical practitioners, dental surgeons, and advanced students.

At a meeting of the Council of the College held on November 10, with Sir Cecil Wakeley, President, in the chair, Professor G. Grey Turner was re-elected as the representative of the College on the Council of King's College, Newcastle-upon-Tyne.

Diplomas of Membership were granted to the 173 successful candidates for the licence of the Royal College of Physicians of London (*Journal*, November 12, p. 1122).

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians of London to T. H. Work and in Ophthalmic Medicine and Surgery to J. H. Owen-Flood.

St. Woolos Hospital, Newport, Mon., was recognized in respect of the six months' resident surgical appointment required of candidates for the Final Fellowship examination.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

In connexion with the 350th anniversary of the foundation of the Faculty Mr. Archibald L. Goodall, Honorary Librarian, will deliver the Finlayson Memorial Lecture entitled "The Royal Faculty of Physicians and Surgeons" in the Hall of the Faculty, 242, St. Vincent Street, Glasgow, on Wednesday, November 23, at 5 p.m. The lecture is open to the public.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 29. [No. 43

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Stillbirths	150	20	29			176	27	36		
Rate per 1,000 total births (including stillborn)			34					40		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

Notifications in England and Wales in the week ended November 5 were: poliomyelitis 318 (347), polio-encephalitis 12 (20). Figures for the previous week are shown in parentheses.

Multiple cases were reported in the following counties: London 50 (55), Bedford 6 (2), Berks 7 (3), Buckingham 2 (4), Chester 16 (10), Derby 3 (2), Devon 3 (3), Dorset 7 (3), Durham 3 (2), Essex 24 (26), Gloucester 6 (9), Hereford 4 (2), Hertford 4 (9), Huntingdon 5 (0), Kent 15 (16), Lancaster 26 (32), Leicester 12 (3), Lincoln, Lindsey 5 (13), Middlesex 14 (17), Norfolk 7 (5), Northampton 4 (1), Northumberland 4 (2), Nottingham 9 (8), Oxford 2 (2), Salop 2 (0), Somerset 2 (11), Southampton 9 (13), Stafford 7 (3), East Suffolk 2 (2), Surrey 6 (14), East Sussex 5 (9), Warwick 7 (8), Westmorland 3 (1), Wiltshire 2 (1), North Yorks 2 (2), West Yorks 36 (50), Glamorgan 4 (7).

Smallpox

In Liverpool a male laboratory assistant aged 16, who handled glassware contaminated with smallpox virus modified by egg passage, has developed smallpox. The onset of his illness was on October 24, the rash appearing on October 27. Primary vaccination had been performed on October 17, soon after he started work in the laboratory. The diagnosis has been confirmed by the isolation of smallpox virus from the pustules: the rash is discrete and modified. The patient was isolated on October 29, and contacts have been vaccinated and placed under surveillance.

On November 10 the patient's younger brother, aged 15, living at the same address in Liverpool and unvaccinated at the time of contact, was put under observation with symptoms of early smallpox. His illness is relatively mild.

There is a possibility that the original case may have infected others during the pre-eruptive stage, but all contacts are believed to be under close surveillance, and spread to the general public is not expected.

Typhoid Fever in Salford

There has been a considerable outbreak of typhoid fever in the Salford district. Preliminary inquiries disclosed that all the early cases had taken a meal at the Masonic Hall, Salford, on October 6. Subsequently other cases were found to have had meals at the same place on other dates, and it became apparent that a continuing source of infection had been present. It is thought that some 3,000 persons are at risk.

Up to the present the total of confirmed and suspected cases is 34. The organism is of Vi-phage type E1. Inquiries are being made among the food-handlers at the restaurant. Three are at present under suspicion, and one is excreting organisms of Vi-phage type E1 and is probably a chronic carrier. All food-handlers at the restaurant have been taken off duty temporarily.

Discussion of Table

In *England and Wales* there were decreases in the notifications of whooping-cough 85, measles 57, and acute poliomyelitis 38. The only increase of any size was in the incidence of scarlet fever 63.

Small variations were noted in the incidence of scarlet fever, the largest being an increase of 31 in Lancashire. For the fifth successive week there was a rise in the notifications of diphtheria; the chief feature of the returns was an increase of 7 in Lancashire.

The fall in the notifications of measles was due to the experience of the Midlands; in the south and north the incidence increased. In the combined area of London, south-eastern, and south-western counties a rise of 81 was recorded, and in the north-western and northern counties there was a rise of 70. The largest local changes in the notifications of measles were decreases in the Isle of Ely 55 and in Warwickshire 37, with rises in Norfolk 52 and Lancashire 35.

A further 89 cases of dysentery were notified in the Lancashire outbreaks: Liverpool C.B. 29, Wigan C.B. 16, Ince in Makerfield U.D. 15, and Hindley U.D. 11. The largest returns for food-poisoning were from Yorkshire West Riding, Sheffield C.B. with 37 notifications, and from Warwickshire, Rugby M.B. 24.

In *Scotland* there were small decreases in the notifications of most infectious diseases; the largest fall was scarlet fever 27. The largest returns for dysentery were Glasgow 37 and Dundee 12.

In *Eire* decreases were reported in the incidence of diarrhoea and enteritis 39 and scarlet fever 36. The experience of Dublin C.B. mainly contributed to these falls. Notifications of measles in Waterford C.B. increased by 57, while a fall was recorded in the remainder of the country.

In *Northern Ireland* there were only small fluctuations in the notifications of infectious diseases. A decrease of 12 in the notifications of measles was recorded in Belfast C.B., while an increase of 13 was reported from County Down.

Week Ending November 5

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,048, whooping-cough 398, diphtheria 86, measles 1,082, acute pneumonia 419, cerebro-spinal fever 18, acute poliomyelitis 318, acute polio-encephalitis 12, dysentery 83, paratyphoid fever 7, typhoid fever 11, food-poisoning 94.

Medical News

The Vicary Lecture

Sir Henry Wade, C.M.G., D.S.O., F.R.C.S.Ed., will deliver the Thomas Vicary Lecture before the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Thursday, November 24, at 5 p.m. His subject is "The Barber Surgeons of Edinburgh."

Visits to Canada

It is hoped that any medical men and women who intend to visit Canada will inform the Secretary of the B.M.A. so that information of such visits may be forwarded to the Canadian Medical Association which is anxious to be of help to doctors from the United Kingdom visiting Canada.

Interpreters for the Deaf

The Secretary of State for Scotland has asked local authorities to provide, if possible, the services of a qualified interpreter for the deaf when a deaf or a deaf and dumb person is being medically examined for certification as mentally deficient. This step has been taken as a result of representations made by the Scottish Association for the Deaf.

Christmas Seals

The National Association for the Prevention of Tuberculosis again offers Christmas seals and cards for sale. The profits help to pay for the association's valuable work in educating the public in the prevention of the disease and for the welfare of the tuberculous. The seals have been given by the Canadian Tuberculosis Association and cost 4s. a hundred. The cards are 6d. each, including envelope. Both can be obtained from the Duchess of Portland, chairman of the N.A.P.T., Tavistock House North, Tavistock Square, London, W.C.1, or in Scotland from the N.A.P.T. (Scottish Branch), 65, Castle Street, Edinburgh, 2.

World Research in Alcoholism

The Department of Public Welfare of the State of Illinois publishes monthly an annotated bibliography entitled *World Research in Alcoholism*. This contains abstracts of papers and books on all aspects of the subject of alcoholism and descriptions of the arrangements made by various States to treat and rehabilitate alcoholics. Those wishing to receive copies of *World Research in Alcoholism* should write to the editor, Illinois Department of Public Welfare, Division of the Alienist, 912, South Wood Street, Chicago, 12, Illinois.

British Plastic Surgeon in Turkey

Professor T. Pomfret Kilner, Nuffield Professor of Plastic Surgery in the University of Oxford, left London by air on November 13 for a lecture tour in Turkey organized by the British Council in conjunction with the Turkish Ministry of Health. He will speak in the Universities of Ankara and Istanbul and at hospitals in Ankara and Izmir.

Scholarships for Nurses

The British Commonwealth and Empire Nurses War Memorial Fund will award the following scholarships in 1950: *United Kingdom.*—Royal College of Physicians Scholarship, Sir James Knott Scholarship (limited to a nurse or midwife from Northumberland or Durham), Robert Wood Johnson Scholarship (limited to an English nurse training in child welfare. Countries visited, preferably Canada or Australia) *Dominions.*—Pakistan: Gilchrist Scholarship. Canada: Thomas Wall Scholarship. Ceylon: Mountbatten Scholarship. *Colonies.*—Malaya: Mountbatten Scholarship. Hong Kong: Royal College of Physicians Scholarship (candidates must be colonial nurses). These scholarships will be tenable in a country other than that in which the candidate is domiciled. Nurses and midwives in the U.K. can obtain particulars of the qualifications required from the scholarships secretary of the fund at Dorset House, Stanford Street, London, S.E.1 The entrance form must be completed before January 31, 1950. Selected candidates will then be required to write an essay on "What contribution has nursing made, and can nursing make, to the life of your country?" On the results of this essay a short list will be interviewed for final choice. Candidates from the Dominions and Colonies will be selected by the appropriate authorities there.

Scientific Films

A film on "Tracing the Spread of Infection: Pemphigus Neonatorum," made for the Ministry of Health by the Central Office of Information, was shown at the C.O.I. on November 11. Intended mainly for teaching pupil midwives, it illustrates how the infection may spread from any of the contacts of the infant, and the laboratory methods used in tracing it. The photography and commentary are clear, though in view of the purpose of the film it is questionable whether it should have included such detailed illustration of the laboratory work required in carrying out the coagulase test and phage-typing. It was made with the advice of the Medical Research Council Cross-Infection in Hospital Wards Subcommittee and the Central Midwives Board. Copies of the film (35 mm. and 16 mm.) may be borrowed after November 30 from the Central Film Library, Imperial Institute, London, S.W.7, by those with their own sound projectors. It will also be available on C.O.I. mobile units, for which application should be made to the appropriate regional film officer. His address can be obtained from the C.O.I. at Norgeby House, 83, Baker Street, London, W.1. In either case its use is free of charge.

The London Optical Practitioners Branch of the Association of Scientific Workers showed some scientific films at Friends House, London, on November 10, one of particular interest being a Russian film, with a commentary by Professor J. B. S. Haldane, F.R.S., on blood transfusion experiments in animals. It showed an isolated dog's head supplied with oxygenated blood from a special pump. The head responded to a number of external stimuli; the eyes reacted to light by blinking, and in response to noises the head pricked up its ears. Sometimes the tongue licked round the lips. The film then showed blood being completely drained from an anaesthetized dog, and after ten minutes the blood was pumped back. In due course the dog revived, the pump was detached, and the wound stitched up. On recovery from the anaesthetic the dog seemed none the worse.

Association of Industrial Medical Officers

Dr. L. G. Norman, Chief Medical Officer of the London Transport Executive, has been elected President of the Association of Industrial Medical Officers.

COMING EVENTS

Birmingham Consultants' Meeting

A meeting of the Regional Consultants and Specialists Committee will be held at the Queen Elizabeth Hospital, Birmingham, on November 23, at 5.15 p.m. Subjects to be discussed include reconstitution of the committee and election of representatives.

Cantor Lectures

Mr. D. W. Kent-Jones, Ph.D., will deliver three Cantor Lectures before the Royal Society of Arts (John Adam Street, Adelphi, London, W.C.) on Mondays, November 21 and 28 and December 5, at 6 p.m. His subject is "Bread."

Contraceptive Technique

A lecture and demonstration (on living models) of contraceptive technique will be given by Dr. Marie C. Stopes and Dr. M. Beddow Bayly at the Mothers' Clinic, 108, Whitfield Street, London, W., on Thursday, December 1, at 2.30 p.m. Tickets of admission must be obtained in advance.

SOCIETIES AND LECTURES

Friday

BRITISH INSTITUTE OF RADIOLOGY.—At 32, Welbeck Street, London, W., November 18, 5 p.m., meeting of medical members.

Monday

HUNTERIAN SOCIETY.—At Society of Apothecaries of London, Blackfriars Lane, Queen Victoria Street, E.C., November 21, 8.30 p.m., discussion, "*That Alcohol has Contributed More to the Happiness than to the Misery of Mankind*," proposed by Dr John Y. Dent and Dr. Desmond Curran and opposed by Dr. Henry Yellowlees and Mr. Archibald Crawford, K.C.

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., November 21, 6 p.m., "*The Contribution of Surgery to Preventive Medicine*," Heath Clark Lecture by Sir James Learmonth.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—November 21, 6 p.m., "*Bread*," Cantor Lecture by Mr. D. W. Kent-Jones, Ph.D.

UNIVERSITY COLLEGE, Gower Street, London, W.C.—November 21, 4.45 p.m., "*Bacterial Toxins*," by Dr W. E. Van Heyningen.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At University New Buildings (Anatomy Lecture Theatre), Edinburgh, November 22, 5 p.m., "*Pancreatitis*," by Dr. Thomas C Hunt

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—November 22, 5 p.m., "*Histopathology of the Skin*," by Dr. I. Muende.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Postgraduate Medical School of London, Ducane Road, W., November 22, 3 p.m., "*Radiotherapy in Non-malignant Uterine Haemorrhage*," by Dr. Mary D Gilmour.

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., November 22, 6 p.m., "*The Contribution of Surgery to Preventive Medicine*," Heath Clarke Lecture by Sir James Learmonth.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—November 22, 5 p.m., "*Development and Behaviour in Childhood*," Charles West Lecture by Dr. N. B. Capon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—November 22, 3.45 p.m., "*A Quantitative Approach to the Study of Transplantable Tumours*," Imperial Cancer Research Fund Lecture by Dr. James Craigie.

Wednesday

INSTITUTE OF PHYSICS: LONDON AND HOME COUNTIES BRANCH.—At Royal Institution, 21, Albemarle Street, London, W., November 23, 5 p.m., "*Physics of Atmospheric Pollution*," by Dr. A. R. Meetham. Joint meeting with Royal Meteorological Society.

INSTITUTE OF PSYCHIATRY (UNIVERSITY OF LONDON), Maudsley Hospital, Denmark Hill, London S.E.—November 23, 4.30 p.m., lecture-demonstration for postgraduates by Dr E. Stengel.

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., November 23, 6 p.m., "*The Contribution of Surgery to Preventive Medicine*," Heath Clark Lecture by Sir James Learmonth.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—November 23, 5 p.m., "*The Royal Faculty of Physicians and Surgeons*," Finlayson Memorial Lecture by Mr. Archibald L. Goodall.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—November 23, 3.30 p.m., "*Mechanization in its Relation to the Public Health*," by Dr. W. Blood.

SOCIAL PSYCHOTHERAPY CENTRE, 7, Fellows Road, London, N.W.—November 23, 5 p.m., "*E.C.T. and Short Methods in Relation to Psychotherapy*," by Dr. A. Joyce Martin.

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Medical Society of London, 11, Chandos Street, Cavendish Square, London, W., November 23, 6.15 p.m., meeting of Microbiological Panel, "*Recent Work on the Bacteriology of Pasteurization*," by Messrs. E. B. Anderson and L. J. Meanwell.

Thursday

BRISTOL UNIVERSITY.—At Canynge Hall, Bristol, November 24, 5.15 p.m., "*Disorders of Speech*," by Dr. Macdonald Critchley.

EDINBURGH CLINICAL CLUB.—At B.M.A. Rooms, 7, Drumsheugh Gardens, Edinburgh November 24, 8 p.m., "*Emergencies in Cardiac Practice*," by Dr I. G. W. Hill.

HONYMAN GILLESPIE LECTURE.—At Anatomy Theatre, University New Buildings, Teviot Place, Edinburgh, November 24, 5 p.m., "*Pleurisy*," by Dr. James Laurie.

KING'S COLLEGE OF HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill Road, London, W.—November 24, 5.30, p.m., "*Food and Mankind*," by Professor John Yudkin.

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., November 24, 6 p.m., "*The Contribution of Surgery to Preventive Medicine*," Heath Clark Lecture by Sir James Learmonth.

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., November 24, 8.15 p.m., "*Psychiatry and the Defence*," by Dr W. L. Neustatter

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—November 24, 5 p.m., "*The Barber Surgeons of Edinburgh*," Thomas Vicary Lecture by Sir Henry Wade.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—November 24, 4.30 p.m., lecture-demonstration "*Psychiatry*," by Dr D. Curran.

TORQUAY AND DISTRICT MEDICAL SOCIETY.—At Torbay Hospital, November 24, 8.30 p.m., "*Headache*," by Dr. Anthony Feiling

Friday

KENT AND CANTERBURY HOSPITAL, Canterbury.—November 25, 5 p.m., clinical meeting.

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES MEDICAL SCHOOL, Maida Vale, London, W.—November 25, 5 p.m., clinical demonstration by Dr. P. H. Sandifer.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—November 25, 8 p.m., general meeting. "*The Ocular Aspects of the Venereal Diseases*," by Professor A. Sorsby.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—November 25, 8 p.m., "*The Aetiology of Neoplasia*," by Mr. A. H Duncan.

UNIVERSITY COLLEGE, Gower Street, London, W.C.—November 25, 5.15 p.m., "*Transmission of Excitation in Nerve and Muscle*," by Dr. Bernhard Katz.

APPOINTMENTS

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—*House-physician* (*Junior Registrar grade*), J. A. Davies, M.B., B.S. *House-surgeon* (*Junior Registrar grade*), A. J. Alldred, M.B., Ch.B. *Resident Anaesthetic Registrar* (*Registrar Grade*), Elizabeth P. Champion, M.B., B.S. *Junior Resident Anaesthetic Registrars*, Margaret E. Browne, M.B., Ch.B., Phyllis M. de Saram, M.B., B.S. *Part-time Orthopaedic Registrar* (*Senior Grade*), G. R. Parry, M.B., B.S. *Registrar to Ear, Nose, and Throat Department* (*Senior Registrar Grade*), B. H. Pickhard, M.B., B.S., D.L.O.

KALRA, ATAM P., M.B., B.S., D.P.H., D.C.H., Medical Officer of Health to Braintree, Witham, and Dunmow, and Assistant County Medical Officer of Health, Essex.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Brueton.—On November 7, 1949, at Southmead Hospital, Bristol, to Nancy (nee Baldwin), M.B., Ch.B., wife of Neville Brueton, M.B., Ch.B., a daughter.

Nicholson.—On November 8, 1949, at Lynfield, The Downs, Altrincham, to Rosabelle and Frank Nicholson, a daughter.

Robertson.—On November 11, 1949, at the Radcliffe Infirmary, Oxford, to Ruth (née Colyer), wife of Dr. D. N. Struan Robertson, a daughter.

MARRIAGES

Blythe—Skidmore.—On September 10, 1949, at Tettenhall Church, Wolverhampton, Frank Blythe, of Woodthorpe, Nottingham, to Clarice A. Skidmore, M.B., B.S., of Tettenhall.

DEATHS

Cooper.—On October 21, 1949, at The Ark, South Bersted, Bognor Regis, Sussex, Ludford Cooper, M.D., late of Devonshire Place, London, W., and formerly of Rochester, aged 82.

Fairweather.—On November 7, 1949, at Purdown House, Stapleton, Bristol, David Stanley Fairweather, M.D., D.P.M., aged 48.

Godfrey.—On November 5, 1949, at Appleton House, Hinckley, Leics., Harry Munn Godfrey, M.D., aged 57.

Gudson.—On November 13, 1949, at 28, Town Walls, Shrewsbury, Leonard Joseph Godson, M.R.C.S., L.R.C.P., aged 80.

Harding.—On November 13, 1949, Robert Dennis Harding, D.M., M.R.C.P., D.T.M.&H., of Stonerush, Wootton Courtenay, Minehead, Somerset.

Macfarlane.—On November 8, 1949, in a nursing-home, Aylmer Alexander Macfarlane, M.D., of 2, Gwydyr Mansions, Hove, Sussex.

Macleod.—On November 10, 1949, at Glenavon, Bradford-on-Avon, George Ernest Macleod, L.R.C.P.&S.Ed., L.R.F.P.S., Surgeon Commander, R.N., Ret.

Prior.—On November 6, 1949, at Bournemouth, John Ralph Prior, M.D., D.P.H., aged 75.

Swayne.—On November 10, 1949, Francis Griffiths Swayne, M.B., B.Ch., of Pen-y-Plock, Tillington, Hereford, aged 85.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Immunization Against Colds

Q.—*Is there any method of immunization which will protect an individual against recurrent catarrhal colds during the winter?*

A.—It is now generally accepted that the common cold, and probably similar catarrhal infections of the upper respiratory tract, are due to viruses which have not yet been specifically identified. Protection against the primary virus infection is therefore not to be expected by the use of bacterial vaccines unless the vaccine in some way increases non-specific resistance to the common cold. It seems likely, however, that secondary bacterial infection is a common complication of the primary coryza, probably as a result of the damage to the respiratory mucosa. The bacteria concerned are mostly those already present in the throat, particularly pneumococci, *Haemophilus influenzae*, haemolytic streptococci, and probably some strains of *Neisseria catarrhalis*. Stock vaccines containing these organisms have for many years been used for the prophylaxis of catarrhal infections, and, although control trials have failed to show any significant benefit, many practitioners believe from their personal experience that these anticatarrhal vaccines have some value. Autogenous vaccines made from the pathogenic bacteria present during the later stages of a cold are also used, and these may be preferred, particularly when there is evidence of persisting sinus infection due to a specific organism. Some catarrhal infections may have an associated allergic factor, and here again the vaccine may act as a desensitizing agent. Avoidance of fatigue, damp footwear, and rapid changes of temperature probably helps to maintain resistance against these catarrhal infections.

Chronic Urticaria

Q.—*How should one investigate a case of chronic urticaria? What are the possible methods of treatment?*

A.—The most important items in the investigation of chronic urticaria are a very detailed history and a full physical examination, bearing in mind that the following are the main aetiological factors: foci of infection, foods, drugs, and psychological disturbances. Less often endocrine disturbances, parasites such as worms, and other skin lesions such as scabies and epidermophytosis are the cause; more rarely contact allergens and physical agents (cold, heat, light), and very rarely inhalant allergens. Radiological and laboratory investigations are usually necessary in the search for infection, which must be thorough. Skin tests are of little value, and in inexperienced hands may be misleading. Cooke (*Allergy in Theory and Practice*, London, 1947, p. 306) summarizes the allergist's viewpoint excellently when he writes: "Thirty-five per cent are due to infection, usually focal, 10% are caused by foods, and another 10% by drugs. This leaves nearly half of our cases aetiologically undiagnosed."

Foci of infection should be removed and, where this is impossible, vaccine therapy given. Drug allergy should always be suspected, and it is wise to stop all drugs, apart from antihistamines, for two to three weeks. "Headache powders," purgatives, and the occasional sleeping-tablet must be specially inquired for and stopped. Food allergy may be suspected from the history, but often can be properly investigated only by dietary trial. The foods commonly found responsible are those the patient usually eats—that is, egg, milk, wheat, potato, fish, chocolate, and fruit; and the writer has had a few successes by stopping all tinned foods. Suspected foods should be eliminated, one or two at a time, for two or three weeks, and during this period all traces of these foods must be avoided—for example, egg is contained in cakes, mayonnaise and sauces of all types, meringues and various pastries, etc. Each food or drug tested by elimination must then be added in the quantities usually taken and the effect during the following two to three days observed.

Psychological disturbances play an important part in many of these cases, and the help of a psychiatrist is often required. A lead might be obtained from a history of previous or accompanying psychological symptoms, such as palpitations, insomnia, headache, or vague dyspepsia; and especially so if a history of emotional stress preceding or accompanying the urticaria was obtained. "Sodium amytal" is useful in these cases. Urticaria at the menopause often benefits from stilboestrol. For suspected insect bites the liberal application of D.D.T. powder next to the skin, during the night and in the daytime, should be tried for four to five days: a few cases, especially if of the papular type, are dramatically eased.

The best symptomatic treatment is obtained with the antihistamine drugs. The large majority of cases can be controlled with suitable dosage; drowsiness during the day should be avoided and this side-effect taken advantage of during the night. They can safely be used for long periods. Non-specific treatments with peptone, histamine, vitamin K, calcium, and autohaemotherapy are of little value; they have been given up by many workers in this field. Sometimes, however, when such treatment is being tried one can by careful observation find the underlying cause which has previously been missed.

Quinine in Late Pregnancy

Q.—*The use of quinine to induce labour is now generally deprecated, but some years ago there were numerous reports claiming that in small divided doses (1½ gr. (0.1 g.) t.d.s.) during the last few weeks of pregnancy quinine tended to shorten the duration of labour and lessen the intensity of the pains. Is this so? Is there any evidence that in this dosage it causes any harm to mother or child?*

A.—Although the administration of small doses of quinine for a few days before labour had been previously recommended, D. A. Mitchell, acting on the suggestion of Philip Jones, seems to have been the first to advocate its routine use during the last three weeks of pregnancy (*British Medical Journal*, 1930, 1, 144). He as well as other writers claimed that it improved general well-being, made labour shorter and easier, ensured good uterine retraction, decreased the need for forceps delivery, and reduced the risk of puerperal sepsis. These and similar claims appear, however, to have been always based on clinical impressions rather than on controlled observations, and there is no definite evidence to support them. The fact that quinine has lost popularity rather suggests that other observers have not been convinced of its efficacy, but it is still used occasionally in cases in which poor uterine action is anticipated. It is never possible to judge its value, but in such dosage it is unlikely to have an adverse effect on the foetus.

Detection of Porphyria

Q.—*What is the simplest and surest way to detect porphyrin in urine, stools, and blood serum?*

A.—There is no simple way of detecting porphyrin in any body fluids. The importance of porphyrin in diagnosis can be exaggerated, and in practice there are two conditions only in which its presence may be of importance: these are acute porphyria and severe chronic lead-poisoning. The easiest techniques were described last year in a letter to the *Journal* (1948, 2, 659). As the presence of porphyrin in stools is physiological, there is very rarely any need to look for it. In a few cases of porphyria, but not in all, porphyrin can be detected in the serum because it fluoresces red under the black ultra-violet light. In practice, the diagnosis of porphyria is rendered almost certain by a positive response to the Watson and Schwartz test. The other methods necessitate the use of a well-equipped laboratory. In small laboratories the porphyrin may conveniently be concentrated in a barium sulphate precipitate obtained by adding barium chloride to the urine and then eluting it with

ammonia, but this is not a suitable procedure when access to a well-equipped laboratory is not available.

The best account of the subject yet written is the classical monograph by Waldenström, published in *Acta Medica Scandinavica*, 1937, Supplement, 82. An inquirer with a laboratory would also find the following references useful: Watson, C. J., *J. clin. Invest.*, 1934, 14, 106; 1935, 14, 116; 1937, 16, 383. Waldenström, J., *Acta med. scand.*, 1934, 83, 281; *Dtsch. Arch. klin. Med.*, 1935, 178, 38. Roth, E., *Z. klin. Med.*, 1935, 129, 123. Dobriner, K., *J. biol. Chem.*, 1936, 113, 1. Turner, W. J., *Arch. intern. Med.*, 1938, 61, 762. Vahlquist, B., *Hoppe-Seyl. Z.*, 1939, 259, 213. Rimington, C., *Biochem. J.*, 1943. 37, 443. Petrie, E., *British Medical Journal*, 1948, 1, 926.

Dicoumarol in Disseminated Sclerosis

Q.—*Would there be any justification for using dicoumarol in a case of disseminated sclerosis?*

A.—Dicoumarol has been employed to treat disseminated sclerosis because it was suggested that the pathological basis of the disease was a tendency to spontaneous clotting in the blood vessels of the nervous system. This hypothesis has not been generally accepted, and many remain unconvinced that dicoumarol is of any value; moreover, it is not free from risk.

Irregularity at the Menarche

Q.—*Is any treatment required for irregular menstruation in young girls? A healthy girl of 14 started menstruating 18 months ago. The cycle was at first six to seven days every four to eight weeks. Latterly, however, the monthly pattern seems to be lost. She may lose continuously for two or three weeks, then be clear for a week or ten days, then start again. Her general health seems unaffected, and there is no sign of anaemia and no pain. She leads an active life. Is treatment indicated? Can her mother be assured that the girl will grow out of it?*

A.—Menstrual irregularity of this and other types is common at this age, but shows a strong tendency to natural cure within months, or one or two years at the most. If the bleeding is not so heavy as to produce constitutional upset or to interfere with ordinary activities, there may be no need for any special treatment. Thyroid 1 gr. (65 mg.) daily for two or three months often seems to stabilize the cycle in these cases, and calcium might also help. The bleeding is probably anovular in type, but may be a manifestation of either hypo-oestrinism or hyper-oestrinism. If sex-hormone therapy becomes necessary, either of these two possibilities would therefore be covered by giving ethinyl oestradiol, 0.05 mg. twice daily by mouth, administration starting on the second or third day of menstruation and continuing for 20 days. During the last seven days of this treatment ethisterone, 10 mg. three times a day sublingually, should be given as well. The next period is likely to start a few days after the completion of this treatment, and, when it does, repeat the course, giving it three times in all.

Femoral Thrombectomy

Q.—*Is femoral thrombectomy ever undertaken in this country? What are the indications and the possible dangers, and what results have been obtained in any published series of cases?*

A.—Femoral thrombectomy is undertaken in this country, but is not yet established as a regular procedure, many surgeons being content to rely upon Leriche's procedure of procaine block of the lumbar ganglia and the combined administration of heparin and dicoumarol. In certain conditions—for example, after prostatectomy, hysterectomy, haemorrhagic lung infarcts, etc.—one fears to use the anticoagulants in the fullest doses; in these cases ligation of the femoral veins is strongly indicated, and if a clot is encountered at the level of the ligature it must be completely removed above the ligature or it will propagate upwards and manufacture emboli. The removal is done from the iliac veins with forceps such as those designed by Trendelenburg for pulmonary thrombectomy, coupled with a sucker tube with an expanded end. Confirmation that the whole clot has been removed is supplied by the finding in the fragments extracted of the characteristic cap at the end of the clot.

Placental Implants for Rheumatoid Arthritis

Q.—*During a recent visit to Pistány, Czechoslovakia, I was given the opportunity of seeing the operation of placental grafting for rheumatoid arthritis and allied conditions. Is this operation performed in England? If so, what results have been obtained?*

A.—This procedure, which is an empirical one, is not performed in England. The underlying idea is that certain of the hormones which are elaborated in the placenta during pregnancy are of value in the treatment of rheumatoid arthritis. By implanting placental tissue it is hoped that the action of these hormones may be prolonged beyond what might be hoped of injection therapy.

"Rheumatoid Rectal Neuralgia"

Q.—*Is there such a thing as rheumatoid rectal neuralgia? This diagnosis was made recently in a case in which there were no physical signs and the only symptom was rectal pain. I have been unable to find any reference to it in the textbooks.*

A.—There appears to be no scientific justification for the diagnosis of "rheumatoid rectal neuralgia" as an explanation for symptomless rectal pain. The writer has recently heard of this diagnosis being made by a proctologist, but on inquiring the grounds for this opinion he discovered that the word "rheumatic" (or "rheumatoid") was being employed in the mediaeval sense—that is, as a synonym for "painful."

NOTES AND COMMENTS

Jelly-fish and Weever-fish.—Dr. H. S. RUSSELL (Bradford) writes: The answer to the request for advice in treating jelly-fish and weever-fish stings ("Any Questions?" October 1, p. 767) appears to me to be somewhat incomplete. On a recent holiday in Suffolk my small son, aged 11, trod on some stinging fish while coming ashore from a bathe, presumably a lesser weever-fish being responsible. When seen 5 minutes afterwards there was a definite puncture mark seen above the left little toe, with an urticarial weal—radius ½ in. (1.25 cm.)—around it. Intense pain was complained of. A small amount of "anthisan" cream happened to be available and was rubbed into the affected part, which ended the incident completely in about two minutes without any sequelae. May I add that I saw an experienced nurse last night who had a wasp sting while visiting. A little anthisan cream rubbed in at once stopped the pain, though it did not prevent the "lump" from developing. I think these anti-histamine chemicals applied locally in good time save a great deal of trouble to all concerned.

Corrections

The address from which information may be obtained about the Commonwealth Fund fellowships offered by the Commonwealth Fund of New York (November 5, p. 1060) is 35, Portman Square, London, W.1, not Portland Square as printed.

Dr. MAX REISS (Bristol) writes: I would be glad if you would correct a misquotation in the issue of November 5 (p. 1041), in the report of the meeting of the Section of Physical Medicine of the Royal Society of Medicine. The report states: "Dr Max Reiss said that he and Hempel were probably the first to use corticotropic hormone in the treatment of rheumatoid arthritis. . . ." This should read: "Dr. Max Reiss said that he and Hemphill were probably the first to use corticotropic hormone in the treatment of human subjects, and published in 1942 the results of investigations carried out on a group of cases suffering from involutional melancholia (*J. ment. Sci.*, 88, 559)." It is important that this correction should be made, as to suggest that I have treated rheumatoid arthritis is misleading.

Dr. T. M. Montford should have been described as part-time Medical Officer of Health to the Castle Donington Rural District Council in the *Journal* of November 12 (p. 1089).

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY NOVEMBER 19 1949

THE SECRETARY REPORTS

A MORAL OBLIGATION

It will be recalled that in a circular issued to boards of governors of teaching hospitals and regional hospital boards reference was made to a moral obligation to ensure that members of hospital staffs displaced as a result of a change of user should be found other appointments. The exact words of the circular were as follows:

"The present opportunity is taken of emphasizing the Minister's view that, where the board's plans for offering permanent contracts on a revised basis of allocation of duties involve displacement or serious disturbance of consultant staffs (e.g., where it is proposed to change the use of particular premises, or to carry out the work with a reduced number of staff), he has a moral obligation for seeing that the staff displaced or disturbed are given as far as practicable the opportunity of undertaking similar duties elsewhere—a moral obligation which he can only meet through the boards themselves.

"In the case of a regional hospital board, the board should, in the Minister's view, be able in almost every case to arrange for the displaced specialist to be offered duties of similar scope and extent in some other hospital where services in his specialty need strengthening.—It is more difficult for a board of governors to do this, as their administrative control extends over a much narrower field, but they should seek the co-operation of neighbouring regional hospital boards in endeavouring to arrange for the offer of similar work at a regional board hospital; and regional boards are asked to do all they can to assist; in nearly every case the staff concerned are of proved calibre and it will be to the board's advantage to obtain their services. Such offers of alternative duties as part of the review are not, of course, subject to the National Health Service (Appointment of Specialists) Regulations, 1948 (S.I. 1948, No. 1416)."

Resistance to Fulfilment

Recently the question of fulfilling this moral obligation has arisen in London, definitely in the case of one hospital and potentially in the case of others. Already the question has arisen of fulfilling the obligation by arranging for a displaced consultant to be appointed to another hospital without the preliminaries of advertisement. Rather unexpectedly, there are signs that the fulfilment of the moral obligation in this way may be made difficult by the resistance of some or all of the consultants on the staff of the hospital to which it is proposed to appoint the displaced practitioner. Indeed, there has already been an instance in which active opposition has been organized. It would be tragic if this developed into a general attitude. After all, no one knows when as a result of change of user he or she may become a displaced consultant needing an alternative post, for there will be many changes of user in future.

The point I want to make is that hospital staffs should be generous in their attitude to any proposed appointment of a displaced consultant. From what we have seen in the London area it is clear that the Ministry and regional hospital boards are anxious to find suitable alternative posts for displaced consultants, and it would be a pity, to say the least of it, if their efforts were in any way frustrated by members of the profession.

While on this subject, one might add a word of congratulation to those teaching hospitals which have found it possible to take under their wing the members of the consultant staffs of hospitals which have become linked with the teaching hospital. The Westminster Hospital and King's College Hospital come within this category. Where this is done, no problem of displacement arises. It is a pity that other teaching hospitals do not find themselves able to follow the same course of action.

I shall be glad to be informed of any single "displaced consultant" problems which arise as a result of change of user in different parts of the country, for we shall be very glad to give such help as we can.

N.H.S. Superannuation

Recent changes in the N.H.S. superannuation scheme are the subject of a leaflet which has been prepared by the Ministry of Health specially for practitioners on executive council lists and part-time specialists. The leaflet (S.D.H.) has been issued to executive councils, regional hospital boards, and boards of governors of teaching hospitals for distribution.

A point of interest to general practitioners is that from August 1, 1949, an assistant is excluded from the superannuation scheme unless his principal has to obtain the consent of the executive council to his employment. Such consent is required where an assistant's employment is for more than three months.

Normally pensionable age is 65, but general practitioners can apply to the Ministry for an extension to 70. Applications for extension may be made on reaching 60 and should be addressed to the Ministry of Health, Health Services Superannuation Division, Government Buildings, Honeypot Lane, Stanmore, Middlesex.

The qualifying period for a pension is 10 years, and general practitioners who were between 60 and 61 on entering the Service in July, 1948, could not, therefore, get in the minimum number of 10 years to count for pension before reaching 70. The Ministry has made a concession and is now prepared to consider an extension in such cases to 71. In the original scheme the maximum service which could be counted for the calculation of benefits was 40 years. This maximum is increased to 45 years by the amending regulations, with effect from August 1, 1949.

Part-time specialists are reminded that, unless they spend substantially the whole of their time in N.H.S. work and choose to have their benefits on the basis of 1/80 of average remuneration for each year of contributing service, their benefits will be reckoned on the basis of 1¼% of total remuneration over all the years of service in the same way as those of general practitioners.

The normal pensionable age for a part-time specialist is 65 (60 for mental health officers), but where service is extended superannuation contributions may now be paid, and the extended service may count for the calculation of benefits up to 70 years of age (65 for mental health officers). This is subject to an overall maximum of 45 years' service, and in reckoning these 45 years no more than 40 years before the age of 60 (55 for mental health officers) may count.

Remuneration of General Practitioners

We have received—just in time for publication in this week's *Supplement*—the Ministry's reply to the representations made to it on the subject of the aggregate pool of remuneration for general practitioners in the Service.

GENERAL MEDICAL SERVICES COMMITTEE

START OF SECOND YEAR'S WORK

At an all-day meeting of the General Medical Services Committee on November 10, the first of the new session, Dr. S. Wand was unanimously re-elected chairman. In taking the chair he drew attention to the size of the agenda, comprising some 90 items, including the reports of five subcommittees. It had been hoped that the first year would see the end of the most urgent of their problems, but now the committee was confronted with a greater volume of work than faced it a year ago.

Dr. Wand proposed the setting up of an executive committee to relieve the pressure of business on the main body. An amendment that, instead of this, the committee meet every month rather than every two months was not carried, the voting being 15 to 15, and after further discussion the proposal to appoint an executive was agreed to, its duties to be to consider and report on matters referred to it by the main committee, to carry out instructions of that committee, to make recommendations, and, between meetings, to advise the chairman at his request on emergency issues.

A small committee was also set up to review the constitution and procedure of medical services committees, another to review the question of protecting the practices of doctors called up in national emergency, and yet another on the general position of assistants under the Act. On this last point it was suggested that the committee should hear evidence from assistants, turning in the first instance to those who had contributed to the correspondence columns of the *Journal*.

Service Points

A question arose concerning the payment of general practitioners attending the aged and infirm in buildings which were under the regional hospitals board, though the persons themselves came under the Welfare Committee of the local authority. The chairman suggested that the several aspects of this question were a matter for informal discussion with the Ministry, and this was agreed to.

A motion was brought forward from the Cheshire Local Medical Committee expressing the view that, in cases where the local medical committee, the executive council, and the Medical Practices Committee were in agreement on the selection of a candidate to fill a vacancy in the medical services of any district, there should be no right of appeal to the Ministry against the decision of the Medical Practices Committee. The Cheshire representative on the committee said that such an appeal was a reflection on the integrity of the medical profession. Surely an unsuccessful candidate should acquiesce in the decision when the three committees were in agreement. Dr. W. M. Knox said that in Scotland, at a joint meeting of representatives of the bodies concerned, the suggestion was favourably received by the Department of Health that the appointment should be made at executive council level and that any appeal should lie to the Medical Practices Committee. It was stated that this could be done under regulations, without new legislation. This matter, with several resolutions of the recent Conference of Local Medical Committees on the filling of vacancies, was referred to the executive for close examination of the whole matter.

A motion by Walsall which was referred by the Conference to the committee, that the question of the burden of work be taken up with the Ministry at an early date, was considered. It was announced that the same expert statistician, Professor Bradford Hill, who made a survey on behalf of the Insurance Acts Committee in 1939, was now engaged on a similar survey, following exactly the same procedure of taking every fifth name on the list, no matter whether the practitioner selected in this automatic way had a large or a small list or was a general-practitioner specialist. In reply to some criticism of the value of this method, the chairman pointed out that the whole strength of their case as to any increased burden of work rested on the fact that the committee had made no selection of practices at all; everything had been left to the neutral expert.

Another matter which had been before the Conference came forward again in the committee—namely, the admission to the medical list of doctors from adjoining areas. Dr. D. F. Hutchinson said that there had been a number of complaints from practitioners in Middlesex that doctors residing four or five miles away from the place where they had accepted patients had been taken on the list, with the result that the resident doctors had to do much of the emergency work for their patients. It was felt that there should be machinery whereby the Medical Practices Committee was able to refuse admission to a list when the executive council had represented that the doctor's place of residence was too far away from where he had patients. One member pointed out that the remedy lay at executive council level. Freedom for a man to practise in an area was one thing, but whether a doctor was able to carry out his obligations in a proper manner when admitted was quite another. The executive council should have power to approve deputizing arrangements. The chairman, at the end of a considerable discussion, said that it was evident that some clarification of the whole position was needed, and he suggested, and it was agreed, that this matter also be considered and reported upon in all its aspects by the smaller committee.

Discussions with the Ministry

The committee then turned to consider a report on a number of matters which had been the subject of recent discussion with the Ministry, some of them bearing on resolutions passed by the Conference. One question concerned frivolous and unjustified emergency calls. The Ministry had promised to consider ways of giving general publicity to such matters as that requests for visits should be made before 10 a.m. if possible, that the patient should not make unreasonable demands, and so on. It had been suggested that instructions to this effect should be printed on the medical card, but the view of some members of the committee was that propaganda on the wireless and in the newspapers would be more effective. The chairman said he gathered that the Minister would not consider sanctions against patients, so that the words "shall" or "must" could not be used on the medical card, but it was useful for the doctor to be able to point to something specific on the card in justification of his requests. The Ministry's offer to consider publicity on this point was agreed to.

General-practitioner Specialists

The status of general-practitioner specialists also came forward. The Ministry had stated that the assessment of status, with the suggestion for special appeals machinery, would be raised with them in the near future by the Joint Committee representing consultants. Dr. Howie Wood said that the position was that certain general-practitioner specialists were not to be issued with permanent contracts at all. Apparently no effort had been made by the reviewing boards to carry out any investigation into the quality of the work done by the practitioner. Once the lists were made up and there was a clear-cut separation it would be very difficult to get reassessment.

It was useful to have the statement from the Ministry that the subject was one which could probably be dealt with during discussions between the Ministry and the Joint Committee. The Ministry's representatives had promised that if evidence was produced which showed that a principle had been misunderstood or misapplied they would investigate the matter.

Many other questions remained on the agenda of the committee, including the disposal of the several resolutions of the Conference, which were referred for detailed consideration by the appropriate subcommittees or noted for reference at the next meeting with the Ministry's representatives.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

FACULTY OF OPHTHALMOLOGISTS

At the council meeting held on October 14 it was reported that, with reference to the Inter-Departmental Committee which has been appointed to consider the registration of opticians, a Joint Evidence Committee has been set up by the British Medical Association, on which the Faculty is represented.

Mr. J. D. M. Cardell and Mr. J. H. Doggart, the two retiring representatives of the Faculty on the Ophthalmic Group Committee of the British Medical Association, have been re-elected.

A memorandum by Mr. Mackie on the duties included in Category 1 in the terms and conditions of hospital medical staff was considered. Many members considered that this document was in need of considerable modification. The matter is being investigated and legal advice sought. Mr. Mackie's memorandum was passed to the Ophthalmic Group Committee for consideration and reference if thought desirable.

Some confusion had arisen as a result of two apparently conflicting decisions of the council concerning the period of postgraduate training and experience recommended before qualifying as a consultant. The three Royal Colleges in 1946 drew up a list of criteria, having considered the advice of other bodies, including the Faculty, and a minimum of five years was agreed upon. Later, in the early part of this year, on a further request from the Joint Committee for Consultants through the Royal College of Surgeons, the council of the Faculty gave its opinion that 10 years was the necessary period. This was done before it was known that there would not be a division between specialists and consultants. When it was discovered that there would be no division, the decision was rescinded and the original view of five years was confirmed and the appropriate bodies informed.

The annual general meeting will be held on Friday, March 9, 1950, at 2.30 p.m.

WELSH COMMITTEE

The Welsh Committee, newly constituted to be fully representative of the Divisions in Wales, held its first meeting of the session at Shrewsbury on November 2. Dr. H. R. Frederick was appointed chairman and Dr. Graham Williams vice-chairman. Dr. J. Griffith Jones was appointed honorary secretary.

The question of the establishment of a Welsh House was discussed, and members of the Cardiff Division reported on properties that had been inspected with a view to purchase. The committee voted *nem. con.* that it was essential that the Welsh House should be centrally placed in Cardiff.

There was discussion on the possibility of an Annual Meeting of the Association being held in Wales in the fairly near future, and the possibilities are being explored.

The chairman was asked to bring to the attention of the Welsh Board of Health the existence of the committee and its willingness to advise on matters affecting Wales.

Correspondence

Private Practice for M.Os.H.

SIR,—It is impossible to read without surprise the extraordinary letter from Dr. J. Katz (*Supplement*, November 5, p. 207). That public health salaries need attention and that much time has been wasted in securing that attention is perfectly obvious, but Dr. Katz is so wide of the mark in several respects as to seem to wish to attract attention of precisely the wrong sort.

He has not even bothered to get his facts right. To say that the average salary paid to medical officers of health by local authorities is £750 per annum is ridiculous. The *minimum* salary for a whole-time M.O.H. is, of course, £1,100 per annum. If he is referring to assistant medical officers of health he ought to say so; even then the minimum salary of the posts is £710 (including bonus), so that an assistant M.O.H. with two years' service will receive £760. In view of the fact that a number of local authorities pay salaries above the scale level and that a considerable number of assistant medical officers serve as part-time medical officers of health for minor authorities and thus qualify for the higher scale, it is hard to believe that the average salary is less than that paid as a minimum to an officer with two years' service. If Dr. Katz were right, it could only be because the great majority of assistant medical officers were so disgusted with their conditions of service that they resigned after a bare year of work.

Even if the average salary of the assistant M.O.H. were £850, it would still be deplorably low. But is not Dr. Katz's suggestion admirably calculated to produce precisely the wrong impression on an austerity-minded Government and Civil Service? What he says might be rendered as follows: "Here is a large body of men and women who are paid whole-time salaries for work which does not occupy the whole of their time and who have plenty of time for other jobs if they like. Keep their salaries low, but make the lazy fellows stir themselves and, if they want more money, earn it 'on the side.'"

Dr. Katz is, I understand, himself an assistant medical officer of health. One would have expected him to learn that, to the officer who takes his job seriously and is really interested in it, the work of an assistant M.O.H. is a whole-time post in the full sense of the term and a rather exacting one at that. Let us act both honestly and boldly and reaffirm that the work is important enough to deserve recognition on its own merits.

It may well be that in the course of the next few years the general practitioner may find an increasing place in public health, especially in the child health services, as one part of his total work. This, however, will come by degrees, and public health will always depend largely upon a corps of doctors who are specialists in its various aspects and are doing that specialist work whole-time. I take leave to doubt very seriously whether any of the ancient nations which Dr. Katz mentions as relying for their public health work on part-time officers have built up public health services whose efficiency surpasses, or even equals, that of the British service.

And Dr. Katz's last words are the most surprising part of the letter. A doctor who believes that preventive medicine is not real medicine has certainly no place in the public health service; whether he could even be a good general practitioner in the full sense of the term is open to question. I have myself suffered from the inadequacy of public health salaries, and I know that many of my colleagues have had a worse deal than myself, but I believe that I speak for the vast majority of them when I say that we would rather remain underpaid than see social medicine degraded to the status of a sideline which is unworthy of serious attention and whose practitioners are not real doctors. To degrade any one branch of medicine is to begin to degrade the whole. In public health no less than in general practice or consulting practice the good labourer is worthy of his hire, and negotiations should begin—as they have done—and continue with this as an absolutely fundamental principle.—I am, etc.,

Colchester. JOHN D. KERSHAW.

Status of General Practice

SIR,—The question of the status of general practice has worried me for some considerable time. It would appear that it is likely to deteriorate; nothing could be worse for British medicine. Nothing could be worse than to see the ranks of general practitioners filled with discontented, disillusioned, "failed" specialists.

We are all well aware that in order to make general practice attractive we must aim at free access to pathological and other services, general practitioner beds, improved remuneration, and the opportunity, if one so desires, to specialize through and within general practice. Is it the lack of these things that makes specialism more attractive than general practice? General practice was apparently more attractive 20 years ago than it is to-day, and yet it was without these additional attractions.

Is it not the type of person who is being admitted to our medical schools that is wrong? I believe that the medical

Diary of Central Meetings

NOVEMBER

23	Wed.	Health Services Subcommittee of the General Medical Services Committee, 11 a.m.
24	Thurs.	Public Health Subcommittee of the Medical Functional Council, 2.30 p.m.
25	Fri.	Committee on Psychiatry and the Law, 2 p.m.
25	Fri.	Joint Evidence Committee on Registration of Opticians, 2 p.m.
25	Fri.	Venereologists' Group Committee, 2.30 p.m.
29	Tues.	Ethical Rules Subcommittee, 2 p.m.
30	Wed.	Committee on the Postgraduate Education of General Practitioners (adjourned from November 9), 10.30 a.m.

DECEMBER

1	Thurs.	Planning Subcommittee of Occupational Health Committee, 11 a.m.
1	Thurs.	Remuneration Subcommittee of Occupational Health Committee, 2 p.m.
1	Thurs.	Joint Committee of the B.M.A. and the N.V.M.A., 2.30 p.m.
2	Fri.	Committee *re* Capital Punishment, 11.30 a.m.
2	Fri.	Colonies and Dependencies Committee, 2 p.m.
6	Tues.	Proprietary Medicines Committee (*Provisional*), 11 a.m.
6	Tues.	Orthopaedic Group Committee, 2 p.m.
9	Fri.	Medical War Relief Fund Committee, 2 p.m.
15	Thurs.	Journal Committee, 2 p.m.
19	Mon.	Armed Forces Committee, 2 p.m.
22	Thurs.	Occupational Health Committee, 2 p.m.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—Friday, November 25, 8.15 p.m., lecture by Dr. G. D. Kersley: "Recent Advances in Connexion with Rheumatism and the Endocrine Glands."

DERBYSHIRE BRANCH.—At Smedley's Hydro, Matlock, Sunday, November 27, 2.30 p.m., annual general meeting. Dr. E. Grey Turner, Assistant Secretary of the B.M.A.: "Current Affairs."

DORSET DIVISION.—At the Old Shire Hall, Dorchester, Thursday, November 24, 8 p.m., Film: "Peptic Ulcer."

HUDDERSFIELD DIVISION.—At Huddersfield Royal Infirmary, Wednesday, November 23, 8.15 p.m., address by Dr. E. Grey Turner (Assistant Secretary, B.M.A.).

OLDHAM DIVISION.—At Oldham Hotel, Rhodes Bank, Monday, November 21, 9 p.m., Mr. P. G. McEvedy: "Haemorrhoids and Other Conditions of the Rectum and Anus Commonly met with in General Practice."

OXFORD DIVISION.—At Lecture Room, Radcliffe Infirmary Maternity Home, Wednesday, November 23, 8.15 p.m. Annual general meeting. Address by the Chairman of the Division.

ROCHDALE DIVISION.—At Kingsway Hotel, Rochdale, Thursday, November 24, 8 for 8.30 p.m., annual dinner. Members may take medical guests.

SOUTH ESSEX DIVISION.—At Oldchurch Hospital, Romford, Friday, November 25, 9 p.m., clinical meeting.

ST. PANCRAS DIVISION.—At B.M.A. House, Tavistock Square, London, W.C., Friday, November 25, 8.30 p.m., Mr. A. Dickson Wright: "Out-patient Letters."

SOUTH-WEST WALES DIVISION.—At St. David's Hospital, Carmarthen, Sunday, November 27, 2.30 p.m., Annual B.M.A. Lecture by Mr. D. H. Patey: "The Acute Abdomen."

SWANSEA DIVISION.—At Osborne Hotel, Langland, Thursday, November 24, 7.30 p.m., lecture by Sir Horace Evans: "Hypertension with Special Reference to Surgical Treatment."

WEST MIDDLESEX DIVISION.—At Red Lion Hotel, Southall, Friday, November 25, 8.30 p.m., Dr. Clifford Allen: "Psychiatry through the Ages."

WEST SOMERSET DIVISION.—At Yeovil District Hospital, Thursday, November 24, 5.30 p.m., clinical meeting. Mr. E. G. Tuckwell: "Sympathectomy."

Meetings of Branches and Divisions

COVENTRY DIVISION

The first ordinary general meeting of the Division for 1949-50 was held on October 11 and was attended by 55 members. The chairman, Surgeon Commander R. S. Rudland, R.N.V.R., in his inaugural address told of his experiences during the war on H.M.S. *Iron Duke* and H.M.S. *Devonshire*. He described particularly the operation concerned with the return of King Haakon of Norway to his own country in 1945, and also with the surrender of important units of the German Navy. He showed films demonstrating life at Scapa Flow, naval exercises, and incidents in the Suez Canal, Ceylon, and Australia.

The address was greatly enjoyed by the Division, and a very warm vote of thanks was accorded on the proposition of Dr. Meacock seconded by Dr. Elford.

On Sunday, October 16, members of the Division attended Evensong at St. Lawrence Church, Foleshill, Coventry. Lessons were read by the chairman of the Division, Dr. R. S. Rudland, and the vice-chairman, Mr. T. Berrill. It is hoped that such a service will be held each year in the parish church of the chairman of the Division on the Sunday nearest St. Luke's Day.

SOUTH EASTERN COUNTIES DIVISION

At a meeting of the Division held on October 16 a film, lent by the B.M.A. Film Library, showing the anatomy, pathology, and clinical features of angina pectoris was shown and aroused great interest.

The secretary drew attention to the form of certificate required for some of the industrial insurance policies, and it was agreed that a minimum fee of 10s. 6d. would be in order in these cases. The secretary announced that Mrs. McGregor had now taken over the secretaryship of the Royal Medical Benevolent Fund and that she would be grateful for any donations.

The emergency fees that had been agreed upon by the Department and the B.M.A. had in that area been withdrawn. It had always been the custom among the doctors of the Borders to assist each other with this work. The appointments system at hospitals was brought to notice, and while the system itself was welcomed it was felt that it would be inopportune in view of the unfinished condition of the central hospital meantime. The Department of Health had notified the regional hospital board that it declined to pay a special fee for domiciliary V.D. treatment. They had not yet replied to the secretary's note. The secretary reported that it was hoped to discuss this directly with the members of the Department at a meeting at St. Andrew's House.

The position of a new central hospital for the Borders was being discussed by the management board and the regional hospital board, and the secretary asked for the doctors present to indicate whether they would prefer to have it in the neighbourhood of Galashiels, or more centrally in the area. Among those present the opinion was definitely that it should be near Galashiels. (Most of the Galashiels and district doctors were present.)

Dr. McCracken, by letter, raised the question of a fee for lunacy certificates. It was agreed that the secretary should inquire into who was the responsible party for the payment to practitioners. Dr. McGregor raised the question of duplicate certificates for insured persons. The secretary pointed out that the original agreement was that the Ministry of National Insurance should on request issue these certificates, but they now complained that owing to shortage of staff they were unable to fulfil these. The secretary was to take this matter up with the Scottish Medical Services Committee.

TUNBRIDGE WELLS DIVISION

A week-end refresher course was held on October 22-23 at the Kent and Sussex Hospital. On October 22 Sir Stanford Cade lectured on "Malignant Disease: Incidence, Early Diagnosis, and Achievement of Treatment," and Mr. Holmes Sellors lectured on "Malignant Disease in the Chest: Early Signs, Symptoms, and Treatment." At 9 p.m. there was a Brains Trust in which Sir Henry Cohen, Dr. R. M. B. MacKenna, Mr. Holmes Sellors, and Mr. N. L. Capener took part. On October 23 Mr. N. L. Capener lectured on "Backache," Dr. R. M. B. MacKenna on "Skin Eruptions as a Manifestation of Somatic Disorder," and Sir Henry Cohen on "The Genesis and Treatment of Peptic Ulcer."

CHEMOTHERAPY IN THE TREATMENT OF MALIGNANT DISEASE*

BY

E. C. DODDS, M.V.O., M.D., F.R.C.P., F.R.S.

Courtauld Professor of Biochemistry, University of London

The title of this discussion is a little unfortunate in that it would imply that there really is a chemotherapy of cancer. A less misleading title would have been something like "Empirical Attempts at Chemotherapy of Cancer." The term in its classical sense presupposes that one understands exactly the nature of the disease one is attempting to cure. The first example was the use of arsenicals by Ehrlich in the treatment of syphilis, terminating in the triumphant production of "salvarsan" in 1911. Here the mode of infection was known, the nature of the infective agent—the spirochaete—had been demonstrated, and the general pathology of the disease was completely understood. The same applies to the other successes in this field, such as the chemotherapeutic attack on malaria, generalized infections, and so forth.

It is not an overstatement to say that we have no knowledge whatsoever of the causation of the great majority of human cancers, nor have we really any proper understanding of the malignant process which enables cells to multiply and divide and so destroy the host. In certain types of cancer we do know the predisposing factor—for example, in the tar tumours or the tumours in the bladder caused by contact with certain chemical substances in the dyestuff industry. However, we do not know why these agents turn innocent cells into malignant cells, nor what the difference is between the malignant cell and the non-malignant, other than its power of unlimited growth. We cannot stop it once it has been started, except by some ablative form of treatment such as surgery or irradiation. We must therefore admit that anyone attempting chemotherapy is truly working in the dark, and that he must of necessity be an empiricist.

I shall not attempt to give anything like a complete list of the various substances and preparations that have been used in the chemotherapeutic attack on cancer. There is no satisfactory approach to the cancer problem in this way, and most of the preparations that have been used have had a very short vogue and then, with few exceptions, have been abandoned. It is with what can be saved out of the wreck, so to speak, that we are concerned.

Two Groups of Effective Substances

The substances which have an effect on malignant disease may be classified under two headings: (1) those which do not affect the cancer itself but which affect the host background in such a way that growth of the malignant tumour is either not favoured or is suppressed and held in abeyance; (2) those which exhibit a directly poisonous action on the cancer cells, acting preferentially on them as compared with the host tissues.

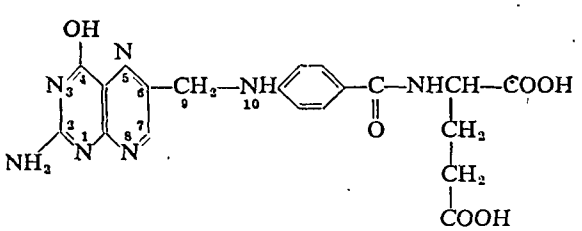
The former substances are well known and are not of fresh interest. One of the most striking examples is the use of stilboestrol, or synthetic oestrogens, in the treatment of carcinoma of the prostate. Stilboestrol is highly active when given by mouth and can replace the naturally occurring substances in every way. When Huggins and Hodges (1941) wished to damp off the activity of the anterior lobe of the pituitary in cases of carcinoma of the prostate they utilized this powerful orally active oestrogen. By cutting off the supply of gonadotrophic hormone to the testes the secretion of androgens is abolished, and carcinoma of the prostate is unable to flourish in a background that does not contain androgens. Stilboestrol therefore produces its good effect, we believe, not by a direct action on the tumour but by altering the background or environment of the tumour so that it cannot flourish. It would appear also that certain carcinogenic hydrocarbons, when given to tumour-bearing animals, alter the balance of some nutritional factor, and it would seem doubtful whether the observed inhibition is due to a direct action on the tumour.

Turning to the second group, we encounter those substances which possess what is known as cytotoxic action. It is well known that a number of chemical substances are capable of preventing mitosis and thereby hindering cell division. An example of these is colchicine. This substance, however, not only inhibits the division of malignant cells but also affects normal ones, and therefore cannot be used as a chemotherapeutic agent. The great toxicity to normal tissues of all the known cytotoxic agents makes their use so hazardous that it is doubtful whether they should be employed.

Two of the most important of the substances used are urethane and nitrogen mustards. The fact that urethane could be employed as a cytotoxic substance was first discovered by Haddow and Sexton (1946). Nitrogen mustard is an analogue of mustard gas, and the one most commonly employed is methyl-*bis*-β-chlorethylamine. It is known that mustard gas itself has a powerful action on the nuclear mechanism, and that it is able to produce mutation by affecting the chromosomes of the *Drosophila* (Auerbach, Ansari, and Robson, 1942, 1943). Careful clinical experimentation has shown that nitrogen mustard seems to have a slightly more toxic action on certain malignant cells than on normal cells.

Folic Acid and Allied Compounds

The greater part of my space will be devoted to the newest comers in this field of would-be chemotherapeutic agents—namely, the folic acid and anti-folic-acid gro-



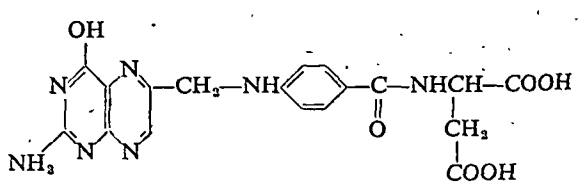
*Read in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Harrogate, 1949.

It is very difficult for anyone who has not visited the United States to realize the tremendous concentration of both laboratory and clinical workers on this group of substances. As the literature on the subject is diffuse, a brief summary of the general position might help readers to get a better grasp of this admittedly complex subject. To indicate how the whole subject of folic acid and allied compounds and their application to the treatment of cancer actually arose it is necessary to review a series of simultaneous researches in relation to malignant disease.

From 1939 onwards appeared a series of papers by Lewisohn *et al.* (1940, 1941a, 1941b, 1942). This work described a search for substances capable of causing regression of spontaneous mammary tumours in female mice of Rockland Farm strain. It was claimed that regression occurred when these animals were treated with extracts from such varied materials as spleen and certain cereals. Attempts to isolate the substance common to all these various extracts yielded only inositol, and it was claimed that this was apparently responsible for the inhibition. These experiments were continued in 1944 (Lewisohn *et al.*, 1944, 1945) and were the subject of a certain amount of controversy. We must now turn to other researches.

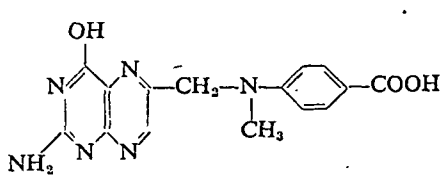
A whole series of workers were studying the growth of bacteria on purified synthetic media. Growth of a number of organisms could be stimulated by the addition of extracts of various substances such as spinach, spleen, and liver. It is neither desirable nor possible to review this work here, but it can be stated that as a result of chemical investigations it became obvious that one factor was responsible for these effects, and that this factor also appeared to be identical with the one used by Lewisohn and his collaborators.

A further series of researches, started in 1935 by Day *et al.* (1938), showed that a certain type of anaemia induced by deficient diet in monkeys could be cured by the addition of extracts of liver, spleen, and green leaves. They called this substance "vitamin M." Again chemical investigation of this suggested that it was possibly the same substance as that mentioned above. A precisely similar story was disclosed in relation to the dietary factors responsible for the growth of chickens and the proper development of their feathers. The substance was identified as pteroylglutamic acid, and the name "folic acid" was adopted for it. The formula of folic acid is:



It has since been synthesized by SubbaRow and his collaborators (Angier *et al.*, 1945, 1946; Waller *et al.*, 1946), and possesses the following characteristics: it crystallizes as yellow pear-shaped platelets; it is sparingly soluble in water (the sodium salt is much more soluble); its physiological properties show that it has a very low degree of toxicity and that it is an essential growth factor for a number of bacteria, animals, and birds. Clinically, its most important action is in Addison's anaemia, in which it is able to cause a haematological remission in the same manner as the liver substance. It will be remembered that it does not protect against the neurological complications, and is therefore different from the liver substance. This we now know to be a crystalline cobalt-containing substance, known as vitamin B_{12}. This was isolated by Lester-Smith (1948) and also by workers in the Merck laboratory in the United States (Rickes *et al.*, 1948).

A further complication is that folic acid may exist free in the tissues or as a peptide. Two such peptides have been synthesized. Whilst folic acid is pteroylglutamic acid, there is pteroyldiglutamic acid, which has been called diopterin, and pteroyltriglutamic acid, which is known as teropterin. In the body these substances are digested, releasing folic acid. Therefore their administration to the human subject has the same effect as the administration of folic acid.



I now return to the researches of Lewisohn and his colleagues. They described the cure of breast carcinoma in three different strains of mice and showed that the active part of their extract was identical with the pteroyltriglutamic acid, or teropterin, referred to above. At a later date SubbaRow and his collaborators (Boothe *et al.*, 1948) synthesized both diopterin and teropterin, and these substances became available in relatively large quantities for clinical research. It is not necessary to review in detail the investigation of the anticancerous activity of these substances, but it can be stated that to-day it is admitted that they are without value in the treatment of both animal and human cancer. The good results obtained by earlier workers in human malignant disease were undoubtedly due to psychological effects, and when carefully controlled experiments were made with blank controls no specific anticancerous effect could be attributed to either teropterin or diopterin. This chapter can therefore be regarded as finally closed, and it must be admitted that neither folic acid nor its peptides are of any value in the treatment of malignant disease.

Modified Folic Acids

I must now turn to further chemical research. The synthesis of teropterin renders possible the preparation of a series of modified folic acids. The numbering of the atoms in the ring systems is shown in the folic acid formula above, and various substitutions can be made. Thus instead of glutamic acid it is possible to make a compound in which aspartic acid replaces the glutamic acid. The compound, which is known as an-fol-A or R, has the following formula:

Similarly, it is possible to take the pteroic acid and prepare methylpteroic acid, which is known as met-fol-B and whose formula is as follows:

Another compound is obtained by substituting an amino group in the 4-position, giving 4-aminopteroylglutamic acid, or "aminopterin." Similarly, in addition to substitution of an amino group at the 4-position, a methyl group

can be attached, as in methylpteroic acid, giving 4-amino-methylpteroylglutamic acid, or A-methopterin. Finally, the aspartic acid compound can be substituted at the 4-position by an amino group, giving 4-aminopteroyl-aspartic acid, or amino-an-fol.

When these substances were tested out physiologically it was found that they possessed very powerful anti-folic-acid activity. The modern conception is that folic acid is essential for the growth of normal cells. This is proved by tissue-culture experiments and by experimental feeding in animals, and of course it is well known to be essential for the growth of bacteria. It will be remembered that Fildes and Woods (1940) showed that sulphonamides act by replacing the normal constituent of the bacterial nutritional requirements—namely, *p*-aminobenzoic acid. It was felt that a similar type of experiment could be done with the anti-folic-acid substances, and that just as one could deceive the bacteria, so to speak, by feeding them with sulphonamides, which could be inhibited by *p-aminobenzoic acid*, so it would be possible to palm off one of these five anti-folic-acid substances on the cells, these substances becoming fixed in the cells so that they ultimately died. The folic acid antagonists act *in vitro* in tissue cultures and will also inhibit the action of folic acid on the growth of bacteria. In mammals they produce a powerful inhibition of the bone marrow, resulting in severe anaemia—effects similar to those seen in folic acid deficiency.

Since these substances interfere with the multiplication of cells, probably acting on the nuclear mechanism, their trial in malignant disease was obviously indicated. They have been investigated extensively for their action on spontaneous and transplanted tumours, and have been found to be effective against a number of them. They have also been used in the treatment of human malignant disease, and particularly in the leukaemias.

Conclusion

It must be pointed out that these bodies are extremely toxic and their use in the human subject is fraught with danger, as the toxic dose is so near the effective therapeutic dose. As Rhoads (1948—personal communication) has so rightly pointed out, it does not really matter from the experimental point of view how close the toxic dose is to the therapeutic dose, provided it can definitely be shown that these substances do exert a specific toxic action on malignant cells. The question of the moment is whether in this series we have the starting-point of a new set of compounds for the treatment of malignant disease; in other words, do these anti-folic-acid analogues occupy the same position in relation to the ultimate chemotherapeutic control of malignant disease as "atoxyl" did to salvarsan?

CHEMOTHERAPY IN THE TREATMENT OF MALIGNANT DISEASE*

BY

Sir STANFORD CADE, K.B.E., C.B., F.R.C.S. M.R.C.P.

Surgeon, Westminster Hospital

Treatment of malignant disease by medicinal means has been tried for many years, and the very multiplicity of the suggested remedies and their short-lived popularity serve only to indicate that none, so far, has proved of value. It must be emphasized that there is no specific remedy which destroys a malignant growth except surgical ablation or radiotherapeutic destruction of the tumour. Nevertheless, advances in biochemistry and biophysics have resulted in the production and use of chemotherapeutic substances which have an effect either on the tumour or on the host, and which so alter the natural course of the disease as to effect remissions, although these are only temporary. The importance of these chemotherapeutic trials lies in their scientific implication; they are pointers or indicators for further lines of research. They are not curative agents, and only a few can be said to be even of palliative value in the control of the disease. It is, however, important from time to time to review present-day knowledge.

The remedies under clinical trial to-day fall into two main groups: (1) those with a cytotoxic effect on the neoplasm, and (2) hormones which alter the "internal carcinogenic environment" of the patient. This expression we owe to Cramer and Horning (1939).

The most interesting substances of the group of cytotoxic poisons are the nitrogen mustards, urethane, and the anti-folic-acid compounds.

Nitrogen Mustard

Nitrogen mustard was first introduced in 1942, and has been used clinically as the "HN2" compound (methyl *bis*-(β-chloroethyl) amine); the "HN3" compound (*tris*-(β-N-chloroethyl)amine) being more toxic and producing widespread thrombosis. The dose generally used is 0.1 mg. per kg. of body weight, given intravenously up to a total of 0.6 or 0.8 mg. per kg. of body weight. It has been tried in many types of tumours—bone sarcoma, melanotic carcinoma, the reticuloses, Hodgkin's disease and lymphosarcoma, carcinoma of the lung, and testicular neoplasms. In some cases visible regression of large tumours, especially masses of enlarged lymph nodes, has been obtained, with a corresponding improvement in the general state of the patient. So far as I am aware there is, however, no recorded case of an apparent regression for prolonged periods. Nitrogen mustard is now used almost exclusively in the terminal stages of lymphadenoma and in cases of cancer of the lung untreatable by surgical or radiotherapeutic methods. It is of palliative value and may restore health for short periods of time—up to nine months in my own experience, but generally for three months only.

The fact that cures have not been obtained should not be a deterrent—on the contrary, it should be an incentive—to the research chemist and biochemist in their search for other mustard compounds more effective and possibly less toxic. Regression of neoplasms, although temporary, is nevertheless very dramatic. Thus in Hodgkin's disease, at a stage resistant to radiation, with fever of either the Pel-Ebstein intermittent type or even the sustained pyrexia type

*Read in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Harrogate, 1949.

in the terminal stages, the temperature drops to the normal level sometimes with dramatic suddenness and remains normal for many weeks. Enlarged lymph nodes shrink or disappear altogether. Occasionally even masses of abdominal glands shrink, but I have not seen any diminution in size of enlarged livers or spleens. In most cases there is a marked drop in the total leucocyte count following the injections, and even a greater corresponding fall in the haemoglobin percentage. One instance of each type of case will be given.

Lymphadenoma.—A woman aged 26; histologically proved case of lymphadenoma treated previously by *x* rays and controlled for two and a half years. Admitted to Westminster Hospital in a moribund condition. Enlarged glands in the neck and groin, large epigastric mass, infiltration of the skin of abdominal wall and left breast, wasting, anaemia, and fever. She was given three injections of HN2, 0.2 mg. per kg. of body weight. The injections were followed by nausea, severe vomiting, and a fall of blood pressure. The reaction subsided in 12 hours. The total white cells fell from 5,200 to 1,100; lowest lymphocyte count 35 per c.mm. Haemoglobin fell from 73% to 56%. There followed within 10 days a rapid and dramatic improvement. The upper abdominal mass almost disappeared; the glands in the neck and groins were no longer palpable, and the skin nodules had vanished. She left the hospital three weeks after admission in near-normal health, and during the subsequent two months her weight increased by 2 st. (12.7 kg.). The improvement lasted four months; recrudescence of symptoms then occurred, culminating in a flaccid paraplegia. Further treatment by nitrogen mustard and *x* rays produced little response, and she died three months later—that is, nine months after the initial treatment. Post-mortem examination revealed widespread disease in the mesenteric glands and around the aorta, and infiltration of the bodies of the fifth to seventh dorsal vertebrae, with compression of the spinal cord.

Carcinoma of the Lung.—A man aged 44. The clinical picture was as follows: cough; shortness of breath; repeated haemoptysis; clubbing of fingers; hard, clinically malignant fixed right supraclavicular glands. Dilated veins on the chest, indicating upper caval obstruction. Radiography of the chest showed a large tumour in the upper mediastinum, enlargement of right bronchial glands, atelectasis of the right upper lobe, and the oesophagus displaced to the left by the tumour. Six injections of HN2, 0.5 mg. per kg. of body weight (a total of 30 mg.), were given in a period of three weeks. The cough, anorexia, dyspnoea, and haemoptysis disappeared. The engorged veins on the front of the chest were no longer visible, and clubbing of the fingers was less marked. The supraclavicular glands were reduced in size to small hard nodules. A radiograph of the chest revealed a marked diminution in the mediastinal mass. So far this patient has remained well for eight months.

To summarize, nitrogen mustard is of value in the treatment of lymphadenoma and carcinoma of the lung as a palliative measure, producing temporary regression of tumour masses and improvement in health. It has no curative value. It is more accurate to say that it postpones death by a few months than that it arrests the disease. Its importance lies in the fact that it produces changes in some types of tumour not dissimilar to the changes produced by radiation.

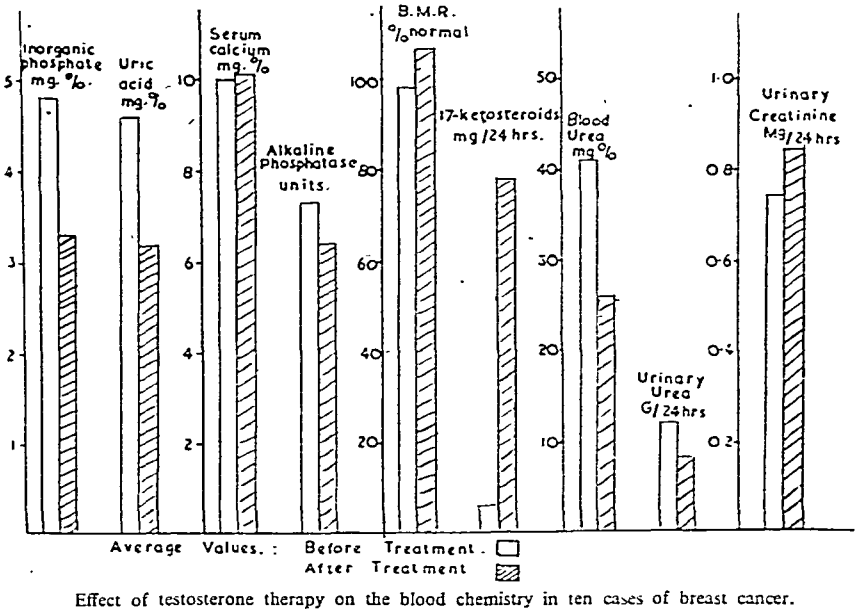
Urethane

The experimental work of Haddow and Sexton (1946) led to the clinical trial of urethane in cases of leukaemia (Paterson *et al.*, 1946, 1947). This substance is given by mouth in doses varying from 2 to 4 g. daily. It produces a fall in the total white cell count and a return of the differential count to the normal proportion. The enlarged spleen diminishes in size. Most cases show a rise in haemoglobin. It is effective both in the myeloid and in the lymphatic types of leukaemia of the chronic form. It has no effect in acute leukaemias. There is a close similarity between the effects of radiotherapy and urethane; the advantage of the drug is that it is effective when irradiation no longer produces regression in the size of the spleen or lymph nodes. There is also sporadic evidence that a relatively small maintenance dose of 1.5 g. daily may be continued for long periods: doses up to 1,500 g. spread over 15 months have been tried. The patient with chronic myeloid leukaemia described by Piney (1947), and who became pregnant during a period of remission following urethane and was delivered of a healthy child by caesarean section, is still alive now, two years later. There is little doubt that urethane is an important addition to the available methods of treatment of chronic leukaemias. Effective although temporary palliation is obtained in the majority of cases. So far there is no indication that urethane can arrest the disease, and cessation of treatment is followed by recrudescence of all clinical manifestations. In therapeutic doses used the red count is not affected; on the contrary, there is a rise in haemoglobin.

Folic Acid Antagonists

Of the new chemotherapeutic agents, "aminopterin" (4-amino-pteroylglutamic acid) is of interest, as it has a marked leucotoxic action and hence has been tried in acute leukaemia. Temporary remissions of this rapidly fatal disease have been reported by Farber and his collaborators (1948). Aminopterin even in small doses of 1 mg. daily is toxic and causes acute lesions in the mucous membranes, ulceration of the mouth and lips, intestinal haemorrhage, haematuria, and purpuric haemorrhages. By courtesy of the Lederle Laboratories I have had the opportunity of putting this substance to clinical trial, so far, in four cases of acute lymphatic leukaemia and in one case of monocytic leukaemia. The first three patients died of their disease; the fourth patient with acute lymphatic leukaemia is under treatment at present.

The fall in the blood count is nevertheless very remarkable—in one case from a total of 76,000 (95% lymphocytic series) to 10,000 (42% lymphocytic and 36% early polymorphonuclear cells). In the case of acute monocytic leukaemia a brief period of great clinical improvement was obtained. All three varieties—lymphocytic, myeloblastic, and monocytic—showed the remarkable and rapid alteration in the blood count. The importance of this group of folic acid antagonists lies in their leucotoxic power. In their present form they are merely that—leucotoxic agents; they have so far shown no curative properties. It is pointed out, however, that further chemical studies and alterations in the molecular structure of these compounds might result in more effective and more prolonged action on the acute leukaemias.



Hormones

The treatment of human cancer by hormones is at present applicable only to cases of cancer of the prostate and cancer of the breast—both organs being physiologically under the control of male and female sex hormones. The great landmarks in this vast, complex, and as yet only partially understood subject are Dodds's (1943–6) production of synthetic oestrogens, Laccassagne's observation on the development of cancer in mice following injections of oestrogens, and Haddow's (Haddow, 1935; Haddow and Sexton, 1946) observations on the effects of carcinogenic hydrocarbons on the rate of growth of spontaneous tumours.

Cancer of the Prostate.—Huggins *et al.* (1939) and Huggins and Clark (1940), of Chicago, after a brilliant experimental study of the physiology of the prostate, established the fact that oestrogens are beneficial in cancer

of the prostate. Stilboestrol has now been used for about nine years, and it is generally accepted that cancer of the prostate can be controlled by it. Survivals of five or more years are not uncommon. The points which may with benefit be emphasized here are as follows: (1) Castration produces effects similar to those obtained by stilboestrol. (2) About 10% of patients with cancer of the prostate do not benefit at all from this treatment. Careful study of this small percentage is more important than the mere recording of the spectacular improvement of the majority. (3) Although most cases receive about 15 mg. of stilboestrol daily, enormous doses—up to 1,000 mg. daily—have been given for several weeks in late cases, with an extension of periods of regression. (4) In no case can it be said that the disease is eradicated—it is checked or controlled. (5) The mechanism of the action of stilboestrol is still not determined, although much is known about it. (6) There is no accuracy in dosage—it is still a method of trial and error.

Cancer of the Breast.—Both oestrogens and androgens are used in breast cancer in women. In cancer of the breast in males oestrogens are of benefit and androgens are not; and in both men and women castration plays a part in the treatment of metastasis. The importance of hormones in the treatment of cancer of the breast lies in their effect on the terminal stages of disease. In early stages radical surgery is the method of choice; in more advanced cases in which the disease is still localized to the breast and its immediate lymph-drainage area the methods of choice are surgery and radiation. But hormones, both androgens and oestrogens, have given us a new weapon to control skeletal and visceral metastases. There is already a considerable and rapidly growing literature on this subject (Adair, 1948; Nathanson, 1947; etc.) I will merely give a brief general account of my personal experience with testosterone propionate in patients with widely disseminated metastases in the skeleton and viscera. There are 50 such patients, and the longest survival period so far in my personal series is two years. No extravagant claims must be made for hormones; neither must their clinical as well as scientific importance be under-estimated. It is indeed the very first time that medicinal means have been able to control some forms of cancer at a stage otherwise quite uncontrollable. The variations in response to treatment indicate that the patient's hormonal state more perhaps than the biological differences in the tumour is responsible for the effects obtained. The study of my personal series confirmed many points noted previously: it does not, however, confirm them all

Effect of testosterone therapy on the blood chemistry in ten cases of breast cancer.

Androgens

Briefly summarized, the observations are as follows:

Age of Patient.—Both old and young patients, pre- and post-menopausal, respond to androgens. The side-effects are more pronounced and less well tolerated by the younger group. These side-effects are hirsuties, change of voice, enlargement of clitoris, and change in appearance and temperament. The side-effects are not necessarily correlated with the dose of androgens. In some patients small doses produced very marked masculinization; in others very large doses produced minimal effects. The younger the patient the larger the dose required to obtain control of the disease.

Type of Metastasis.—Skeletal metastases respond more often, more quickly, and for longer periods than visceral metastases. Regression of lesions has been obtained in secondary deposits in the skeleton, the liver, the pleura, and the brain; also in soft-tissue recurrences—skin, subcutaneous tissue, and lymph nodes.

Effect of Treatment.—Pain from skeletal metastases is relieved in most cases. Ulceration of cutaneous lesions heals. Blood-stained pleural effusion, previously necessitating frequent tapping, no longer reaccumulates. Paresis of cranial nerves or from spinal compression has in a few cases been followed by recovery of power. Involvement of the base of the skull and of the pituitary producing polydipsia and polyuria has been controlled, and an intake of 2 gallons (4.45 litres) or more of fluid daily, with a correspondingly large urinary output, has been reduced to about 50–60 oz. (1.42–1.7 litres) a day. In many cases bedridden, morphinized, and desperately ill patients have been restored to apparently normal health. Thus one patient with widespread skeletal metastases returned for a time to her work as a lady almoner in a hospital and for a year could lead a normal life and take exercise such as dancing. Several patients in terminal stages have returned to a normal existence for periods up to two years so far. X-ray examination shows reossification of osteolytic lesions after three to six months, seldom earlier, and not in every case. In all cases there is an increase in weight, chiefly due to water retention, clinically manifested by diminished urinary output and subcutaneous oedema.

Dosage.—After a careful study of the available reports the dose tried was 150 mg. of testosterone propionate daily by intramuscular injection. Subsequently the dose was increased in about one-half of the patients to 300 mg. daily, till a total varying from 3,000 to 6,000 mg. was reached. In most cases when improvement was satisfactory at the end of this period an implant of 3,000 mg. was given. In a few cases much smaller doses, not exceeding 150 mg. weekly, were tried. There is at present no definite indication of the exact dose.

leucorrhoea, or which is the result of cervical infection, ever causes pruritus vulvae.

2. Glycosuria

The fact that eight of this small series of previously selected cases proved to have glycosuria is significant. The diagnosis of diabetes may easily be missed if at the time of examination the patient has not eaten for several hours and the urine is temporarily free from sugar. If there is any doubt about the cause of pruritus the only safe procedure is a glucose-tolerance test. In glycosuria without diabetes the pruritus is nearly always the result of *Oïdium albicans* infection, which thrives in the presence of a free supply of carbohydrate. The same is true of diabetes mellitus, but there is the added possibility of pruritus being the result of peripheral neuritis or of chemical changes in the skin. The vulva in these cases presents a typical appearance, the tissues being slightly swollen and oedematous with a characteristic dusky blue or purple coloration.

3. Psychogenic Causes

A close relationship between the mind and the skin and the part played by psychological upsets in causing skin diseases are recognized by all. Many psychiatrists emphasize the sexual basis of mental disturbances, so it is little wonder that the skin of the vulva can become the site for manifestations of psychoneuroses. Some hold that nearly all cases of pruritus vulvae have a psychogenic basis, but there is a danger of the importance of this factor being exaggerated. In general, mental and emotional upsets should be accepted as causing pruritus vulvae only when every other possibility has been excluded. When they are merely contributory factors, as they often are, they usually cease to operate when other causes are removed. Among the common psychogenic causes may be mentioned guilt over masturbation, cancerophobia, fear of venereal disease, marital disharmony with an underlying desire to avoid coitus, or a scratch habit.

4. Prolapse

Prolapse either of the uterus or of the vagina seems to be a rare but none the less definite cause of pruritus. Considering how common is prolapse, however, and how infrequently pruritus is a symptom, it is natural to doubt the association, yet a few cases seem to be cured completely by a repair operation. However, the possibility that the cure is due to something incidental to the operation, such as sterilization of the vagina, rest in bed, or a psychological effect, cannot be excluded.

5. Allergy and Drug Sensitivity

Skin sensitivity to various chemical constituents of toilet preparations occasionally cause pruritus vulvae. Sometimes acetarsol, silver picrate, and other drugs used in the treatment of trichomonas vaginitis are the cause of pruritus, or lead to its continuance after the original causal infection is under control.

Apart from urticaria associated with the same condition elsewhere it is doubtful how far allergy is responsible for pruritus vulvae. The possibility has been much discussed and investigated in recent years, and is the basis of empirical treatment with ergotamine and antihistamine drugs. Allergic reaction to the patient's own sex hormones has

bla
par

Skin-sensitivity tests either with endocrine with other possible antigens are rarely and in my experience antihistamine drugs tisfactory results.

6. Leucoplakia Vulvae

Our knowledge of the pathogenesis of leucoplakia vulvae and kraurosis vulvae is as confused and insecure as it was forty years ago, when Berkeley and Bonney (1909) attempted to define them. There is a renewed tendency to return to the older view that kraurosis is the ultimate atrophic phase of leucoplakia. If kraurosis is to be regarded as a condition of extreme atrophy affecting the introitus only and often associated with senile vaginitis, this can hardly be correct. Some writers even distinguish between leucoplakia and leucoplakic vulvitis, and Hunt (1943) regards leucoplakia as a form of lichen planus. The variation in views, few of them supported by convincing evidence, is borne out by Savill (1940) and by Miller and others (1947), together with the discussion which followed this latter paper.

In my experience kraurosis vulvae as originally described is very rare and does not cause pruritus but rather pain and dyspareunia; this feature, which was emphasized long ago by Berkeley and Bonney (1909), tends to be overlooked. Nevertheless senile vaginitis, possibly associated with vulval atrophy, is occasionally associated with pruritus, which responds to oestrogen therapy. Leukoplakia, at least in its hypertrophic phase, is not difficult to recognize. It affects the outer aspects of the labia and may spread to the perineum and around the anus, and is undoubtedly precancerous. It occurs at any age and does not bear any relation to ovarian function, so it is not improved by oestrogen therapy. There is good reason to believe that it may not be a specific entity but merely one type of skin reaction to many possible stimuli: prolonged scratching alone can produce somewhat similar skin changes. It is sometimes the result of vitamin A deficiency, and is also seen occasionally in various types of anaemia and in diabetes. One of the most typical cases of "leucoplakia" I have ever seen was in a doctor's wife who suffered from vitamin B deficiency as a result of a diet which consisted almost entirely of a few water-biscuits a day. The administration of riboflavin quickly restored the vulval skin to normal. The nine cases of leucoplakia shown in the list were "iodiopathic" in the sense that an underlying cause was not demonstrated; there were five other cases in which the leucoplakic skin changes were considered secondary to other causes, and they appear under other headings.

One of the most obscure types of pruritus is that in which the irritation is localized to a very discrete area of thickened pale skin usually situated on one labium majus. It may be mistaken for leucoplakia, although hyperkeratinization and cracking are not pronounced features. It responds badly to treatment—even to excision—and is probably a form of localized neurodermatitis with lichenification.

7. Deficiency States

One of the greatest advances of recent years is the recognition that various deficiency states can cause pruritus vulvae, and the development and details of this knowledge are set out in papers by Swift (1932, 1936), Wright (1944), Stannus (1944), Hughes (1946), and Whitfield (1947). These authors are concerned mainly with the effect of vitamin A and various members of the vitamin B_2 complex. Other agents may operate, however, and among these may be mentioned iron, liver factors, and possibly other vitamins. Pruritus vulvae is therefore occasionally a manifestation of hypochromic or hyperchromic anaemia; it then responds quite dramatically to the specific treatment of these conditions. The lesions produced in the vulva vary from slight

reddening or pallor and oedema to typical leucoplakia. As might be expected, other evidences of deficiency states, such as glossitis, cheilosis, and angular stomatitis, are often found in these cases. It is of interest to note that the scrotum, which is homologous with the labia majora, is also the seat of "dermatitis" in ariboflavinosis (Frankland, 1948).

If obvious local causes such as trichomonas infection are excluded, deficiency states can be shown to be responsible for approximately 20% of the cases of pruritus vulvae. In this country they rarely arise as a result of gross dietetic errors, but such should be looked for, especially in elderly women living alone. More often they are due to some disturbance of the alimentary tract which interferes with biosynthesis or with absorption. The most important factor in this respect, and one whose significance was first pointed out by Swift (1932, 1936), is achlorhydria, which is presumed to act by interfering with the absorption of vitamin A and iron.

Achlorhydria

During the last ten years the investigation of cases of obscure and intractable pruritus seen in private or hospital practice has included a fractional test meal, and the details of 46 women (including the 13 mentioned in the private series) with histamine-fast achlorhydria are available. The mere finding of achlorhydria, which is common in women of advancing years, does not of course prove that it was the cause of pruritus, but the response to treatment suggests that in the majority it was. In four of the cases the skin lesion was typical leucoplakia; in others there was pallor or reddening of the labia majora with secondary changes due to scratching. Although the vulva was the main site of the pruritus the perianal skin was also involved in some cases. A significant degree of hypochromic anaemia was often present. All these patients were given acid. hydrochlor. dil. by mouth, and iron preparations when necessary, but no other general or local treatment, and the immediate results were as follows: cured, 34; slight relief, 1; unknown, 4; no response, 7.

Leucoplakia was present in two of the seven failures, and excision was required; in another case monilia infection explained the itching. It seems reasonable to conclude that in some of these seven and in the one with only partial relief the achlorhydria was probably merely coincidental, because the usual response to treatment is striking, even dramatic. Women who have had intolerable itching for years get complete relief within one to two weeks. One constant feature, however, is that an associated pruritus ani is not relieved to the same extent.

In order to determine the ultimate effect all of the 34 "cured" cases have been followed up. The findings are as follows:

Permanent cure for 1 to 8 years	25 cases
Died from intercurrent disease	1 case
Not traced	2 cases
Relapsed and did not respond to further treatment	6 cases

Some of those permanently cured report that they need to continue taking hydrochloric acid, otherwise the itching returns at once; this is what one might expect. Others, however, after regular treatment for a few months have been able to discontinue taking the acid for long intervals—even years—without a return of pruritus. This is an extraordinary phenomenon which is not explained by present knowledge but is confirmed by Hyams and Bloom (1947). Also interesting are the six women who were initially cured but did not get relief from the same treatment when symptoms recurred. One of these was ultimately cured by an operation for prolapse; another can be kept comfortable only by periodic blood transfusions. In her case hypochromic anaemia persists or recurs despite the administration of hydrochloric acid and iron.

Opinions differ about the relative importance of achlorhydria as a cause of pruritus vulvae. Swift (1936) originally stated that it is responsible for *all* cases of leucoplakia and kraurosis; Haultain (1948) says that it is present in 30% of cases of leucoplakia; while Hyams and Bloom (1947) put the figure at 60%. Miller *et al.* (1947), however, deny it any significant place in the aetiology of leucoplakia vulvae. In my experience it accounts for approximately 20% of cases of "pruritus" for which there is no obvious local cause, and is present in about one-third of women who have what I regard as real leucoplakic changes in the vulval skin. In these the vulval lesion is not always reversed by the administration of hydrochloric acid. Moreover, and despite the statement of Hyams and Bloom (1947) to the contrary, *hypo*chlorhydria is rarely, if ever a significant finding in pruritus vulvae, and the acid deficiency must be complete if it is to operate. The fact that leucoplakia in association with achlorhydria is often not cured by administering acid raises the question whether it represents a skin reaction which has progressed so far as to be irreversible. Such a concept is in keeping with the observations of Stannus (1944) to the effect that in ariboflavinosis the essential pathology is capillary damage, and that the vascular disturbance may lead ultimately to permanent skin changes.

Even when dietetic errors and alimentary upsets are excluded there still remains the possibility of a local tissue deficiency to account for some cases of pruritus vulvae. This might occur, for instance, if the blood supply is inadequate; and the question then arises whether surface ischaemia in leucoplakia is the cause or the result of poor nutrition to that area. Deficiency states, vascular disturbances, and pruritus have some close association. A vascular upset is often the basis for itching, as, for example, in urticaria and in varicose veins of the legs, the latter being accompanied by faulty nutrition to the skin. It is tempting to suggest that venous stasis is the significant lesion when pruritus vulvae seems to be caused by prolapse. The view that some local circulatory factor may cause pruritus vulvae is also supported by the fact that when the vulva is excised for leucoplakia healthy skin brought from other sites to cover the area often undergoes leucoplakic changes.

Even when the supply of essential factors is normal the local tissues may be unable to utilize them, and in this connexion it is interesting to note that it has been suggested that diabetes mellitus can produce pruritus by interfering with the utilization of vitamins by the skin or by promoting their rapid excretion. Carrying the argument further, it may be pointed out that when senile states cause pruritus vulvae the nutritive factor which is absent is oestrogen.

The only types of pruritus which are difficult to account for on the basis of a general or local nutritional deficiency are those due to trichomonas and fungus infection. It may be postulated, however, that, since these infections are so specific in their pruritus-producing character, perhaps the organisms concerned have a special metabolism which deprives the host tissues of some vital factor. They or their metabolic products may act as antivitamins or toxamins; this suggestion is purely hypothetical, but its validity deserves serious inquiry.

One of the difficulties in accepting the concept of poor nutrition of the tissues as the basis of pruritus vulvae is

that, with the exception of those cases which show a positive therapeutic test, there is little concrete evidence to support it. In some of our cases Professor R. A. Morton kindly carried out estimations of the amount of carotene and vitamin A in the plasma, and in none was any significant decrease demonstrated. This agrees with the findings of Porter and Godding (1945) in relation to various skin disorders, and with those of Miller and others (1947) and Hyams and Bloom (1947) in respect of leucoplakia vulvae. The last-named workers were also unable to demonstrate any biochemical evidence of vitamin C and vitamin B_2 deficiency. The negative findings in regard to vitamin A, however, are not necessarily conclusive, because it is now known that the plasma content of this vitamin remains normal for very long periods after it has been completely withdrawn from the diet (Glover, Goodwin, and Morton, 1947) and is not easily altered by administering vitamin A. Moreover, local deficiency states, if present, cannot be demonstrated by examination of the blood and urine.

Management and Treatment

From the foregoing it is clear that the most important part of the management of pruritus vulvae is a thorough investigation to find the cause. This necessitates taking a very careful history and making a full physical examination, and the minimum requirements as regards special tests are: (*a*) repeated examination of *fresh* vaginal swabs for trichomonas and *Oïdium albicans* and other fungi; (*b*) fractional test meal; (*c*) full examination of the blood; (*d*) glucose-tolerance test; and (*e*) biopsy of vulval skin in selected cases. Unless a cause can be found treatment is mostly unsatisfactory.

Antipruritic ointments are of little use except as temporary measures and perhaps to break the scratch habit. The injection of local analgesics gives disappointing results, and the division of all cutaneous nerves is usually short-lived in its effect. The place of radiotherapy in the treatment of pruritus vulvae is very strictly limited and should be used only as a last resort and after very careful consideration. Although it may give relief by a mechanism unknown, the pruritus, if caused by a persisting factor, usually returns. Moreover, *x* rays and radium are apt to produce permanent skin damage, which can itself be the cause of intractable pruritus. Oestrogen therapy is useless except when there is clear evidence of failure of ovarian function, and it may even be dangerous in precancerous lesions such as leucoplakia.

Leucoplakia appears to be helped sometimes by emollients (including cod-liver oil) and also by the local application of heat as suggested by Savill (1940), the idea being to improve blood supply. Often, however, nothing short of vulvectomy is of real value, and this should not be deferred too long, because of the possibility of malignant disease. Excision is of limited value except for clearly demarcated lesions such as leucoplakia, and even then there is a tendency for the condition to recur in the surrounding areas. Unless there is evidence of achlorhydria, gross dietetic errors, or other lesions characteristic of a deficiency state, the empirical administration of vitamin preparations even in massive doses is rarely helpful, despite a few enthusiastic reports to the contrary. Moreover, if, as postulated above, any deficiency state in these cases is of local origin it is unreasonable to expect a response from such medication.

Throughout this paper the emphasis has been on the obscure and difficult cases of pruritus vulvae, and the same is true in regard to treatment. Lest it convey too gloomy a view of the general picture it is perhaps fitting to conclude by emphasizing that even in the present state of knowledge a definite organic cause amenable to treatment can be found in not fewer than four out of every five women who complain of pruritus vulvae, and in not more than 5% is it impossible to give real relief by one means or another.

RELIEF OF POST-OPERATIVE PAIN AND ITS INFLUENCE ON VITAL CAPACITY

BY

H. E. POOLER, M.B., D.A.

Senior Anaesthetist, Chesterfield Royal Hospital

It has been recognized for many years that post-operative pulmonary complications occur much more frequently after surgical operations involving the upper abdomen than after those on other parts of the body (King, 1933: Campbell and Gordon, 1942). It is indeed significant that we are now more likely to hear the expression "post-operative chest" than the more old-fashioned "post-anaesthetic pneumonia."

In Table I is shown the incidence of post-operative pulmonary complications in a series of 5,869 anaesthesias. These were all personally administered and examined post-operatively by me, thus introducing a reasonably constant factor and ensuring that approximately the same minimum of abnormal physical signs in a chest qualified it for the label "pulmonary complications."

TABLE I.—*Post-operative Pulmonary Complications*

Site of Operation	No. of Cases	Pulmonary Complications
Upper abdomen ..	331	63 (19%)
Lower abdomen ..	1,334	145 (10·9%)
Outside abdomen* ..	4,204	29 (0·7%)
Total ..	5,869	

* Does not include thoracic surgery.

Why this high incidence of pulmonary complications following abdominal operations and especially those on the upper abdomen? Langton Hewer (1948) lists several main causes of post-operative lung complications, including "impaired respiratory movements after operation and

the patient to cough." It seems reasonable that the impaired movement and reluctance conditioned to a large extent by the pain of efforts.

Observation in the surgical wards will soon convince one that operations involving interference with the abdominal walls are much more productive of these conditions than are operations remote from the abdomen, and that the nearer the operation is to the diaphragm the more reluctant is the patient to cough and the greater is the impairment of respiratory movement, hence the greater likelihood of pulmonary complications.

Churchill and McNeil (1927) and later Powers (1928) showed that an upper abdominal operation lowered the vital capacity on the first post-operative day to 25–30% of the original volume, lower abdominal operations to 50% of the original volume, but operations on the limbs had little effect on vital capacity.

Table II shows some of the results obtained by me. They are quite typical of our usual findings. A portable spirometer (pneumometer) was used, and the patient was placed in approximately the same position in bed for all readings

TABLE II

	Operation	Sex	Age	Pre-operative Vital Capacity	Post-operative First-day Vital Capacity	Post-operative % of Pre-operative Vital Capacity
Upper abdomen	1. Subtotal gastrectomy	M	45	2,700 c.cm.	900 c.cm.	34

* It is interesting to note that the pre-operative vital capacity of Case 11 was recorded half an hour after his premedication with "omnopon," gr. ¼ (22 mg.), and hyoscine. gr. 1/150 (0.43 mg.), and that the post-operative readings of both Cases 11 and 12 were taken only ten hours after operation.

Lassen (1938–9) published similar figures. While he agrees that the fear of pain caused by coughing and deep breathing plays some part, he believes the chief factor is reflex muscle spasm, since the exhibition of morphine does not increase the post-operative vital capacity.

Morphine is still our great standby for the relief of pain, and in the absence of some strong contraindication no one would deny the drug to any patient after a severe operation. No doubt in vast numbers of cases it does a great deal of good and no harm. But morphine is well recognized as a respiratory depressant, so it cannot be an ideal drug to relieve pain when it is also desirable to increase pulmonary ventilation. With this latter factor in mind it was decided to try other methods of relieving post-operative pain, especially after upper abdominal operations. Apart from Lassen's work I have been unable to trace any literature dealing with the effect of sedative drugs on the post-operative vital capacity. In his article the only drug mentioned is morphine, and this very briefly. After some thought it was decided to use procaine in the form of an intravenous drip. Intravenous drip procaine had already become a recognized therapeutic measure (Lundy, 1942; Gordon, 1943; Graubard *et al.*, 1947, 1948). It was felt that the dilute solutions required to produce general analgesia would not produce any significant decrease in muscle tone, especially in view of the well-known fact that sensory anaesthesia is normally established before appreciable muscular paralysis occurs when dilute procaine solutions are used for nerve-blocking.

At first all that was sought was to produce a quick analgesia, then to encourage the patient to cough until sputum was produced, and then to carry out the routine breathing exercises as taught to him pre-operatively by the physiotherapist. This proved very satisfactory so far as it went. It was surprising, and most gratifying, to see the amount of sputum produced by a patient who had not previously complained of chest symptoms and had not experienced any desire to cough. It was felt that this routine of coughing followed by deep breathing must be preventing the onset of many potential areas of scattered atelectasis, and quite likely was clearing up some patches of collapse already established.

The technique used was a slow intravenous drip of 1% procaine in normal saline; the rate of the drip was carefully increased until the patient's pain was considerably relieved or until he complained of subjective symptoms such as "feeling light-headed" or "feeling dizzy." In practice these subjective symptoms always coincided with considerable relief of pain. In an average-sized adult this point was reached in about 5–10 minutes after the infusion of 15–20 ml. of the 1% solution. The drip was then slowed down and the coughing routine instituted. This technique necessitated the personal supervision of the anaesthetist, as it was obvious that the intravenous use of 1% procaine was not without its dangers and the well-known vagaries of intravenous drips precluded anything but continuous observation. In a hospital where anaesthetists are rather at a premium this technique could not be carried out on many patients.

The following three case reports are typical of the results obtained and indicate that the procedure is well worth while, despite the disappointing effect on the vital capacity after pain relief. As will be seen, the increase of vital capacity was not impressive.

Case Reports: Technique I

Case 1.—Man aged 45. Subtotal gastrectomy for chronic duodenal ulcer. Anaesthetic: soluble thiopentone, 1.7 g., N_2O+O_2, and *d*-tubocurarine, 25 mg. Duration: two hours and ten minutes. Pre-operative vital capacity: 2,700 c.cm. Post-operative vital capacity: first day, 900 c.cm. (34% of pre-operative value). He already had a "rusty" sputum, and rales were heard in all areas. There was considerable pain, aggravated by coughing or attempted deep breathing. The intravenous drip transfusion of 1% procaine completely relieved his pain, enabled him to cough up a considerable amount of rusty mucopurulent sputum, and apparently enabled him to take deep breaths in comfort, but the vital capacity was increased by only 400 c.cm. to 1,300 c.cm.—that is, only 47% of its pre-operative value, a gain of 13% on the first post-operative reading.

Case 2.—Man aged 47. Subtotal gastrectomy for chronic duodenal ulcer. Anaesthetic: soluble thiopentone, 1.5 g., N_2O+O_2, and *d*-tubocurarine, 30 mg. Duration: two hours and five minutes. Pre-operative vital capacity: 2,500 c.cm. Post-operative vital capacity: first day, 1,000 c.cm. (40% of pre-operative value). Pain was fairly severe, and was much aggravated by attempted deep breathing. Intravenous transfusion of 1% procaine almost completely relieved his pain. Strong but painless coughing produced thick viscid sputum. Vital capacity increased by 200 c.cm. to 1,200 c.cm., or 48% of the pre-operative value—a gain of 8% on the first post-operative reading.

Case 3.—Man aged 49. Subtotal gastrectomy for chronic duodenal ulcer. Anaesthetic: soluble thiopentone, 1.75 g.,

N_2O+O_2 (minimal cyclopropane during closure of peritoneum), and *d*-tubocurarine, 35 mg. Duration: two and a half hours. Pre-operative vital capacity: 2,500 c.cm. Post-operative vital capacity: first day, 600 c.cm. (24% of pre-operative value). Great deal of pain, much aggravated by attempted deep breathing. Intravenous transfusion of 1% procaine greatly relieved the pain. Vital capacity increased by 200 c.cm. to 800 c.cm., or 32% of pre-operative value—a gain of 8% on the first pre-operative reading.

No serious subjective symptoms were encountered while using this technique. The initial drip is given very slowly, so that a patient with an idiosyncrasy to the drug would show mild warning symptoms before enough had been infused to do him real harm. Johnson and Gilbert (1946) have shown that reactions to procaine occurring during drip transfusions of the drug are easily controllable and need not be alarming. Using a 1% solution of procaine to obtain obstetric analgesia, they carry a patient into a semiconscious state for the actual delivery. Such dosages as "8 g. in 6 hours, 9.5 g. in 8 hours, and 9.7 g. in 8½ hours" illustrate the distance we have travelled since the time when intravenous injection of a local analgesic was looked upon as a serious accident occurring occasionally during the production of regional analgesia.

Since the publication of Barbour and Tovell's (1948) experiences using a 0.1% solution of procaine, with an average adult dosage of 1 g. in one hour for the treatment of many different pathological conditions, I have used a similar technique for the relief of pain after upper abdominal operations. The advantages are that subjective symptoms of overdosage rarely occur and the patient need not be under personal supervision after the first few minutes. Actually, despite the greater dilution, the patient receives a much bigger dose, which appears to be a good deal more effective. The relief from pain is more lasting. With the use of Technique I (1% procaine) the patient obtains good relief for two to three hours. With Technique II (0.1% procaine) the relief lasts as long as six to eight hours.

The solution used is procaine, 1 g. in 1,000 ml. of 5% dextrose in normal saline. The procaine should not be mixed with the dextrose saline until required, as the resultant solution becomes discoloured after a few hours. The effect on the vital capacity is still disappointing, but is rather better than that achieved by Technique I, as the following typical case reports indicate.

Case Reports: Technique II

Case A.—Man aged 36. Subtotal gastrectomy for chronic duodenal ulcer. Anaesthetic: soluble thiopentone, 1·7 g., N_2O+O_2, and *d*-tubocurarine, 22.5 mg. Duration: two hours. Pre-operative vital capacity: 3,000 c.cm. Post-operative vital capacity: first day, 1,100 c.cm. (37% of pre-operative value). Not severe pain—complete relief after 1 g. of procaine, given in one hour by intravenous drip transfusion. Vital capacity increased by 500 c.cm. to 1,600 c.cm., or 53% of pre-operative value—a gain of 16%. Post-operative vital capacity: second day, 1.800 c.cm. (60% of pre-operative value). After 1 g. of procaine by intravenous drip, vital capacity increased to 2,100 c.cm., or 70% of pre-operative value—a further gain of 10%.

Case B.—Man aged 46. Subtotal gastrectomy for recurrent gastric ulcer following partial gastrectomy three years previously. Anaesthetic: soluble thiopentone, 1.5 g., N_2O+O_2, and *d*-tubocurarine, 30 mg. (+minimal cyclopropane during maintenance to overcome hiccup). Duration: three hours. Pre-operative vital capacity: 3,000 c.cm. Post-operative vital capacity: first day, 1,100 c.cm. (37% of pre-operative value). Not severe pain, but complete relief after 1 g. of procaine in intravenous drip over one hour. Vital capacity increased by 400 c.cm. to 1,500 c.cm., or 50% of pre-operative value—a gain of 13%. Post-operative vital capacity: second day, 1,500 c.cm. (50% of pre-operative value). After 1 g. of procaine the vital capacity increased to 1,800 c.cm., or 60% of pre-operative value—a gain of 10%.

Case C.—Man aged 52; a case of jejunal ulcer and gastro-colic fistula. Operation: undoing of 20-year-old gastro-jejunostomy, closure of gastro-colic fistula, and subtotal gastrectomy. Anaesthetic: soluble thiopentone, 1.75 g., N_2O+O_2, and *d*-tubocurarine, 30 mg., with occasional small doses of cyclopropane to secure quiet respiration during difficult surgical manipulation. Duration: three hours and ten minutes. Pre-operative vital capacity: 2,400 c.cm. Post-operative vital capacity: first day, 1,000 c.cm. (41% of pre-operative value). Rather severe pain much aggravated by attempted deep breathing. No desire to cough. Good relief obtained by procaine, 1 g., in intravenous drip over one hour. No sputum produced by coughing. Deep breathing now almost painless. Vital capacity increased by 500 c.cm. to 1,500 c.cm., or 62% of pre-operative value—a gain of 21%.

Case D.—Man aged 67. Repair of perforated duodenal ulcer. Anaesthetic: soluble thiopentone, 0.5 g., N_2O+O_2, and *d*-tubocurarine, 15 mg. Duration: 25 minutes. Pre-operative vital capacity: unknown. Post-operative vital capacity: first day, 1,000 c.cm. Severe pain. Great relief after 1 g. in intravenous drip over one hour; coughing then produced copious sputum. Vital capacity increased to 1,200 c.cm. Post-operative vital capacity second day, 1,400 c.cm. No abnormal physical signs in the chest. There can be little doubt that this patient would have developed major pulmonary complications if he had not been able to expectorate freely on his first day.

For each case a vital capacity chart (a specimen of which is illustrated) is filled in, as well as the usual "Copeland-Chatterson" record card.

Conclusion

From the work done so far it would seem that Lassen (1938–9) is right when he asserts that the post-operative lowering of vital capacity is not altogether due to the fear of increase of pain on deep breathing. If this were the whole story, then complete relief of pain should restore the vital capacity to its normal volume, but this by no means happens. If, as seems likely, Lassen's assumption that reflex muscle spasm is the chief factor is correct, then something more than the abolition of conscious pain is required. In fact, it is likely that only by interrupting the reflex arc on its afferent side can we abolish this muscle spasm and still leave the muscles under full voluntary control, thus enabling the patient to take the deep breath required to produce his normal vital capacity.

Since writing the above I have had the opportunity of reading an article by McCleery, Zollinger, and Lenahan (1948) in which they have shown that a significant increase of the post-operative vital capacity can be achieved, after upper abdominal operations, by injection of the sixth to the eleventh intercostal nerves with a slowly absorbed solution of 1:1,000 "nupercaine" in peanut oil. They claim that injection in the mid-axillary line does not interfere with the motor supply to the intercostal muscles. This procedure should not only relieve pain but should also break the reflex arc on the afferent side, yet the average increase of the vital capacity was still only 16 to 17%, which is not much above the average increase obtained with intravenous procaine (12 to 13%).

It seems not unreasonable to conclude that if we could hold a post-operative vital capacity at its pre-operative volume we should considerably reduce the incidence of post-operative pulmonary complications. But that this would not complete the story was shown by Rees-Jones (1941), who demonstrated that during the first 24 hours after an abdominal operation either the diaphragm on the

ipsilateral side was fixed or its excursion very much reduced, while on the contralateral side movement was free; yet the only case in his series to develop pulmonary complications produced a lower-lobe atelectasis on the contralateral side

Summary

The incidence of pulmonary complications following upper abdominal operations remains high.

After an upper abdominal operation the vital capacity is regularly decreased to the region of 35% of its pre-operative volume.

Intravenous drip procaine is an excellent method of relieving post-operative pain in cases in which it is important not to decrease pulmonary ventilation.

There is evidence that some increase of vital capacity follows the relief of post-operative pain by this method in abdominal cases. This increase, however, is so small that it is suggested that other theoretical causes for the lowered vital capacity need investigation.

LOW-SALT DIET IN TREATMENT OF HYPERTENSION AND HYPERTENSIVE HEART DISEASE*

BY

H. O. BANG, M.D.

P. BECHGAARD, M.D.

AND

A. LEVIN NIELSEN, M.D.

(From Medical Departments 2 and 7 of the Municipal Hospital, Copenhagen)

The treatment of heart disease and hypertension has of late attracted much attention, thanks especially to papers by Allen and Sherrill (1922), Schroeder (1941), Schemm (1942), and White *et al.* (1946). Kempner (1944) claimed to have seen an exceptionally favourable response of hypertension to his salt-poor "rice diet." The favourable effect on these diseases was, however, observed far earlier by Karell (1866), Achard and Loeper (1901), and Widal and Lemierre (1903). In Denmark, Finsen (1904) proposed a low-salt diet in diseases associated with oedema. According to recent American experiences a rigorous restriction of the salt content of food (under 0.75 to 1 g. of NaCl daily) is necessary, at least in the case of hypertension.

*Read before the Scandinavian Congress of Medicine, Copenhagen, on June 30

Present Investigation

Our object has been to test the above American results. In particular we have tried to prove that sodium chloride alone is the deciding agent and that the possible favourable response to the dietary treatment is not due to other factors, such as confinement to bed and rest in hospital.

Diet.—Originally we used a diet containing about 2,500 calories, but we soon had to reduce it to about 2,000 calories, the patients being unable to eat it all. The solid food consists of :

Morning: 45 g. white bread (salt-free), 10 g. butter (salt-free), 5 g. sugar, 1 g. tea.

Either simultaneously or later in the morning: 25 g. oatmeal (as porridge, cooked without salt), 5 g. sugar, 125 g. stewed fruit.

Supper: 100 g. white bread (salt-free), 30 g. butter (salt-free), half an egg, 50 g. tomato (or 100 g. apple or 10 g. cucumber), 25 g. fresh meat (or 20 g. fish), 10 g. lemon juice with 10 g. sugar (or 50 g. juice in water).

Dinner consists of fruit jelly as the first dish (without milk), and boiled or fried (in salt-free butter) fish or meat, with vegetables and potatoes afterwards. The composition of the diet per day, calculated after Sherman's tables, appears to be : sodium 262 mg., chlorine 385 mg., calcium 254 mg., iron 7.9 mg., with protein 50 g., fat 88 g., and carbohydrate 258 g., giving 2,019 calories. The diet is insufficient with regard to calcium, and perhaps vitamin B and iron. During the experimental periods we added daily doses of vitamins A and D and gave a weekly injection of a vitamin B preparation.

Material.—The series consisted of 26 patients, all admitted to the Municipal Hospital, Copenhagen. They presented such a degree of hypertension that after a fortnight's confinement to bed they still had a systolic blood pressure above 180 mm. Hg and/or a diastolic pressure above 120 mm. Hg. Seven of the patients were men and 19 women, with ages ranging between 45 and 71 years (average 59). Their hypertension had been recognized from well over 1 year up to 14 years previously. None of the patients seemed to suffer from the rapidly progressive malignant form of hypertension The hypertension was in most cases complicated by heart disease (possibly with insufficiency), retinopathy, or nephropathy. In the accompanying table the patients have been grouped according to diagnosis, with the uncomplicated cases at the top, and then the different complications in order of increasing severity. Patients whose urea clearance was less than 50% of the normal value have been entered under a diagnosis of nephropathy. None of the patients had had syphilis or rheumatic fever.

Experimental Period.—During the preliminary fourteen days the blood pressure was measured frequently, and patients in whom it fell below the above limits were not submitted to treatment. A number of the less severe cases were therefore excluded. Four days before starting treatment with the low-salt diet we began to take the blood pressure of each patient in the morning; preferably this was done by the same physician, at least three times. The blood-pressure values are based on the lowest recorded for each day. The values stated in the table are means for the last four days. Column I gives means for the preliminary period, column II for the low-salt-diet period, and column III for the control period of high salt intake. During the preliminary period we measured the chloride and nitrogen excretion daily for two or three days. Ophthalmoscopy was carried out, as well as radiography of the heart, electrocardiography with precordial deflection,

SYMPTOMATIC TREATMENT OF MYOTONIA ATROPHICA

BY

L. BUSSELL, D.M., B.Sc., M.R.C.P., D.C.H.

Clinical Assistant, Royal Infirmary, Sheffield

The value of the antihistamine drugs in increasing mobility in Parkinsonism has been noted by various clinicians. This spasmolytic action of the antihistamines is probably due to lengthening of the refractory period of muscle, which then becomes unable to maintain a tetanus. Such an action has been demonstrated on isolated rabbit auricle for quinidine, pethidine, procaine, and other local analgesics (Dawes, 1946). It was later shown that "anthisan" ("neoantergan") was twice as potent as quinidine in this respect (Dews and Graham, 1946).

In the case described below this action of the antihistamine drugs was applied to the treatment of myotonia atrophica.

Case Report

The patient, a Derbyshire farmer aged 49, presented the classical features of myotonia. The facial expression was woebegone, with bilateral cataract and receded frontal hairline. The neck was so wasted that his collars had become unserviceable, and on special occasions he resorted to a neckerchief. There were weakness and wasting in the arms, legs, and small hand muscles, with a delay of several seconds in release of the handgrasp. He was unable to cut up his own food at meals or to do heavy work. He managed, however, to run a small poultry farm, clumping around with a noisy stamping gait, and carrying buckets of water or poultry meal on the crook of his best forearm. The testicles were atrophied and bronchiectasis was present. He had had four attacks of pneumonia in recent years. Although friendly enough with his doctor, others found him moody and difficult.

Symptoms began in 1943, but the condition escaped diagnosis until 1946, when quinine was given with benefit. Treatment lapsed after the first few weeks and had not been resumed.

He was the only member of the family to show the full picture of the disease. His grandfather and father both suffered from senile cataract. His grandfather was a powerful man of great physical stature, who narrowly missed recruitment into the Life Guards. Both his grandfather and his father had been exceptionally heavy beer-drinkers. The patient's brother, a middle-aged man, and the brother's two daughters were said to suffer from short sight. All three wore glasses with lenses of startling thickness. The patient himself had two healthy sons in their teens.

Treatment was started in June, 1949, with 50 mg. of "benadryl" three times a day. After one week the patient was able to use a knife and fork and to cut up his own food for the first time for two years, and he began to carry buckets of water in the normal way by hand. There was objective improvement in the myotonia of the hands, and the small hand muscles became firmer to palpation. He was then given 200 mg. of anthisan three times a day for a further two weeks. Improvement continued, and he was able to fork dung and "sweep out" with greater effect than before. The myotonia of the hands was not, however, altogether abolished.

Discussion

The patient was not a good subject for assessment of a therapeutic remedy. The severe wasting placed a limit on the value of spasmolytic drugs, while the mental condition introduced a big subjective factor. If the value of antihistamines in myotonia is confirmed, they might be employed in two ways: the antihistamine drug could be given with quinine to obtain a summation effect, or the two drugs could be given alternately, say for a week each, to avoid the unpleasantness of cinchonism.

In considering the treatment of myotonia atrophica it is well to take account of the relationship between this disease and myasthenia gravis. A pharmacological antithesis is recognized between these two diseases, drugs which benefit the one causing an exacerbation in the other (Goodman and Gilman, 1941). It was thought possible that this antithesis might operate in the case of the thymus gland. Tumours of this gland are sometimes found in myasthenia, and a remission in the disease sometimes follows thymectomy. Accordingly, after three weeks' antihistamine treatment in the above case it was decided to try the effect of thymus-gland administration. For a fair trial it would be necessary to give fresh gland extract, by injection. As fresh extract is not readily available, dried thymus tablets were given by mouth for a month—10 gr. (0.65 g.) thrice daily. There was no objective change. The patient, however, reported continued subjective improvement, with increase of the myotonia in the hands after withdrawal of the tablets. This may have been a psychological effect, and owing to the preceding antihistamine treatment the experiment was considered inconclusive. It did, however, succeed in showing that thymus gland by mouth does not provide a replacement therapy for the disease

Further work on the antihistamines is required to establish whether antihistamine and spasmolytic action run parallel. If this is so, the newer and more potent antihistamines should repay trial in myotonia. It is also possible that some of the local analgesic substances possessing a quinidine-like action on rabbit auricle (Dawes, 1946) may prove suitable for clinical use in myotonia.

In general it is to be expected that drugs such as quinine which benefit myotonia would also be beneficial in the rigid type of Parkinsonism.

Summary

A pharmacological basis for the action of spasmolytic drugs in Parkinsonism and in myotonia atrophica is described.

On this basis a spasmolytic agent which is active in one of these diseases should also be active in the other.

A case of myotonia atrophica is reported. Benadryl and anthisan both produced striking symptomatic improvement.

The possible role of the thymus gland in myotonia atrophica is discussed.

I wish to express my thanks to Professor Wayne for helpful criticism and for permission to treat the case.

Mayfield and Hedrick present in the United States *Journal of Nutrition* (1949, **37**, 487) a study of the nutritive value of protein in foods and how it may be affected by the various processing procedures. The effect of varying the type of cattle feed and subsequent changes of roasting and corning on the digestive and biological value of beef protein were studied. Canning caused a lowering in the biological value and digestibility of the beef, but roasting and corning produced no change.

AN UNUSUAL CASE OF SIMMONDS'S DISEASE

BY

DERMOT McCRACKEN, M.B., M.R.C.P.

Assistant Physician, Last Hospital, Ashton-under-Lyne

True cases of Simmonds's disease due to lesions of the pituitary other than a post-partum necrosis are rare. One essential part of the syndrome is some destructive lesion of the anterior pituitary, and in many of the cases reported erroneously as Simmonds's disease there has been no such lesion.

The case reported below fulfils all the requirements for a diagnosis of this disease, and the primary lesion was a carcinoma of the pituitary gland. There are several interesting features in the case.

Case Report

The patient, a man aged 54, was admitted in October, 1947, to the Lake Hospital, Ashton-under-Lyne, following a haematemesis of 1 pint (570 ml.) of blood. He continued to vomit clots of blood immediately after admission. He was very apathetic and a good history could not be elicited from the patient himself. His wife said that he had been in poor health for years and had lost a lot of weight. He had been having severe attacks of neuralgia in the face and head. The previous year he had undergone tonsillectomy and an operation upon his nose.

In February, 1947, he had been admitted to the neurosurgical department of another hospital because the head pain was persistent. It was then thought that the ill-defined pain in the left side of the face and ear was due to a lesion in the central grey matter for which little could be done. As the pain was so severe, however, operation was undertaken to relieve it: intracranial division of the ninth nerve, the upper fibres of the tenth nerve, and the lower part of the fifth root was performed. He improved somewhat and was discharged in March, as all investigations to find a cause for the pain were negative. It was thought at the time that a deep secondary deposit could possibly have accounted for the pain, but no lesion was demonstrated.

For two months previous to admission to this hospital for haematemesis he had been having epigastric pain almost immediately after food. He was given the usual treatment for haematemesis, and vomiting ceased 48 hours after admission, but he continued to have melaena for 10 days and was given blood transfusions of 2 pints (1.14 litres) and 1 pint. He began to improve, and the haemoglobin rose from 38% on Nov. 3 to 80% on Nov. 18. He suffered from epistaxis on several occasions in the last half of November, but said this had occurred at intervals since the nasal operation. It did not affect the blood picture appreciably. Despite the improved blood picture the patient continued to be very apathetic and took little interest in things. All efforts to increase his weight failed.

He came under my care in April, 1948, when the picture was much the same. The main symptoms were wasting, apathy, lassitude, and anorexia. He appeared much older than his years: his skin was dry and inelastic and his face wrinkled and creased. His hair was fine, blond, and scanty on the head, in the axillae, and in the pubic region. The pain in the head was still present but was less troublesome. He had pronounced arteriosclerosis and his blood pressure was 85/55. The only other findings on examination apart from considerable wasting and asthenia were weak heart sounds, an inactive left pupil, and some brownish pigmentation on pressure areas of the back. There was no pigmentation of the skin or mucous membranes elsewhere. The diagnosis seemed to lie between Addison's disease and Simmonds's disease.

Investigations at this stage showed: blood urea, 21 mg. per 100 ml.; urinary chlorides, 2 g. per litre. Cutler's test: urinary chlorides, 288 mg. per 100 ml. Glucose-tolerance curve: fasting, 74 mg. per 100 ml.; half-hour after glucose, 74 mg.; 1 hour after glucose, 109 mg.; 1½ hours after glucose, 127 mg.; 2 hours after glucose, 118 mg. Serum chlorides, 280 mg. per 100 ml.; serum sodium, 316 mg. per 100 ml. The Wassermann reaction and Kahn test were negative.

In view of the positive Cutler's test and low serum chloride he was given desoxycortone acetate, 10 mg. daily, and sodium chloride by mouth from April 22. There was an initial improvement, the patient becoming mentally more alert and his blood pressure rising to 128/70 mm. Hg. As the response was not as satisfactory as had been hoped for, the desoxycortone acetate and salt were discontinued on May 3 pending further investigations, as it was still doubtful whether the diagnosis was Addison's disease or Simmonds's disease. He became drowsy and his appetite was poorer when the desoxycortone acetate was discontinued. On May 7 the serum sodium was 276 mg. per 100 ml. On May 8 Kepler's test showed: serum chloride, 280 mg. per 100 ml.; urine NaCl, 175 mg. per 100 ml.; urine urea, 1.9%; blood urea, 26 mg. per 100 ml.; largest morning specimen, 2 oz. (57 ml.); night urine, 8.4 oz. (234 ml.). Therefore factor A = 27.8, giving positive Kepler's test I and doubtful Kepler's test II.

Desoxycortone acetate and salt, 10 g. daily, were restarted, but the patient's condition became rather poorer. The systolic blood pressure dropped to 95 mm. and he had to be fed because of extreme apathy. His anaemia was increasing, and the blood picture on May 20 was: red cells, 3,650,000 per c.mm.; haemoglobin, 74%; colour index, 1.03; white cells, 9,900 per c.mm.

Despite the evidence of adrenal insufficiency it was considered that this was not enough to account for the whole clinical picture, and that there must also be pituitary insufficiency. The 17-ketosteroids were estimated and found to be 1 mg. per 24-hour specimen. On June 5 it was considered that in view of his downward progress and the doubt about the diagnosis it would be justifiable to give 5 units of soluble insulin subcutaneously immediately before glucose and a meal in an effort to increase his weight; but pronounced hypoglycaemia resulted. Intravenous glucose was given and the patient apparently recovered. One hour later he again became hypoglycaemic, requiring further intravenous glucose. His blood sugar on this occasion one hour *after* the first and apparently sufficient injection of glucose was 13 mg. This was taken as definite evidence that there was also pituitary insufficiency.

The evidence for involvement of both pituitary and adrenal glands was: positive Cutler's test, positive Kepler's test I, doubtful Kepler's test II, low blood sodium, very low 17-ketosteroids, marked insulin sensitivity, and hypotension.

The patient was also given 200 units of "antuitrin S" daily and ½ gr. (32 mg.) of thyroid three times a day, as some clinicians consider this has been of clear benefit in occasional cases of Simmonds's disease.

Nine days later the patient could not be roused in the morning and was found to have a left facial hemiparesis with gross dilatation of the left pupil and a left extensor plantar response. Glucose was given intravenously immediately (after taking a specimen of blood). The patient recovered consciousness and lost the focal signs. He was soon himself and the blood-sugar result received later showed a level of 13 mg. per 100 ml. Despite glucose, 20 g. three times daily, this was only the forerunner of several spontaneous hypoglycaemic attacks, and he died on July 26. The last blood count, on July 19, showed an increase in the anaemia: red cells, 3,110,000 per c.mm.; haemoglobin, 62%; colour index, 1; white cells, 8,300 per c.mm. (polymorphs 82.5%, lymphocytes 10%, monocytes 5%, eosinophils 1.5%, basophils 1%).

I performed a necropsy, and there appeared to be a growth of the pituitary gland and some atrophy of the adrenals. There was a chronic ulcer on the lesser curve of the stomach which was probably the cause of the haematemesis. The pituitary gland, the adrenals, and a portion of the pancreas were sent for section; the report on these was as follows: "The *pituitary*

by mixing the grated coconut with hot water and manually squeezing out the oil. To reduce the fat content, the mothers were instructed not to add the milk obtained by the initial squeeze, but to discard this and add hot water to the grated coconut. This weaker coconut milk was used for the preparation of the child's curry. The fat-deficient diet was continued for a few weeks after the stools became normal.

Summary

Forty cases of pathologically proved *E. histolytica* infection in infants in Colombo and its environs are presented. Of 291 cases of infantile diarrhoea in children under 2 years of age 15.9% were infected with *E. histolytica*. Fourteen cases were 1 year of age and 26 between 1 and 2 years. Twenty-nine of the cases were infected with *E. histolytica minuta* and the others with the larger type. Half the cases were of the acute and half of the chronic and relapsing variety. Treatment given was by emetine parenterally and carbarsone orally. Of the cases followed up 80% indicated satisfactory results.

ACUTE PHLEGMONOUS CAECITIS

BY

DNEY G. NARDELL, B.Sc., F.R.C.S.

Surgeon, Whipps Cross Hospital, London, E.11

Acute phlegmonous caecitis is not described in any of the standard textbooks of surgery or pathology. Although it is rare it is possible that the small number of cases reported may be due to the condition's not being recognized at laparotomy, or it may be that some cases thought to be of "appendix abscess" which subside on conservative treatment are in reality cases of acute phlegmonous caecitis. The subject was discussed in an excellent article by Spivack and Busch (1943), who reviewed 35 cases recorded up to that time and described two cases of their own. A few more have since been reported.

The purpose of this article is to draw attention to this condition and to describe two cases met with at this hospital. Both patients presented with severe continuous abdominal pain which started in the epigastrium and later shifted into the right iliac fossa. They were not seen until the disease had been in progress for 48 hours, and in each of them a well-defined and extremely tender mass was present in the right iliac fossa. A provisional diagnosis of acute appendicitis was made, but it was felt that the early appearance of such a tender mass was an atypical feature. Operation revealed acute phlegmonous caecitis, with a normal appendix in both cases. In Case 1 the disease was of the diffuse form, the whole of the posterior wall of the caecum being affected and the borders of the phlegmon merging imperceptibly with the normal bowel. Case 2 is of the circumscribed form of the disease, a localized phlegmon of the posterior wall of the caecum being differentiated fairly sharply from the normal bowel. The two cases correspond well with the diffuse and circumscribed forms of the disease described by Spivack and Busch.

Case 1

A married woman was admitted to hospital on March 6, 1948. She had walked to the doctor's surgery in the morning, and on admission gave a 58-hours history of abdominal pain which started in the upper abdomen and later shifted into the right iliac fossa. She vomited once at the onset. The bowels had not been opened since the onset of the pain, and an aperient had been taken without result. She had slight scalding pain on micturition, which was otherwise normal. There was no previous history of similar pain.

On examination her temperature was 100.4° F. (38° C.), pulse 112, and respirations 18. Her tongue was dirty. Herpes labialis was present. An extremely tender mass was palpable in the right iliac fossa in the position shown in Fig. 1, while the remainder of the abdomen seemed normal. Rectal examination revealed no abnormality. The chest and cardiovascular systems were normal, as was the urine. With a provisional diagnosis of acute appendicitis operation was performed under general anaesthesia.

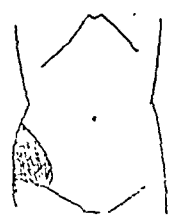

Fig. 1.—The position of the tender mass in Case 1.

The abdomen was opened through a grid-iron incision. There was no free fluid in the peritoneum. A firm mass the size of a golf ball was found in the posterior wall of the caecum, which was very inflamed. It was grossly oedematous and its surface had a grey necrotic appearance. The edges merged imperceptibly with the normal bowel. The appendix was macroscopically normal and was removed. A small fragment of the caecum was taken for microscopical examination. There was no evidence of obstruction due to the mass and there were no enlarged glands. A corrugated rubber drain was placed down to the mass and the incision closed.

Post-operative Course.—Intramuscular penicillin, 40,000 units three-hourly, was started and continued up to a total of 1,750,000 units. A course of 24 g. of sulphamerazine was also given. There was very little discharge from the drain, which was removed on the fifth day. The patient made an uninterrupted recovery, the wound healing by first intention. White blood cells on March 17 numbered 10,350 per c.mm. (polymorphs 63%, lymphocytes 29%, monocytes 6%, eosinophils 2%). After two weeks scarcely any mass could be felt in the right iliac fossa, and when she was discharged from hospital on March 31 nothing abnormal was palpable.

The pathologist (Dr. W. W. Walther) reported: "This appears to be an acute pyogenic infection. There is no evidence of tuberculosis or streptothrix after prolonged search." During the next year the patient was seen at intervals. She remained perfectly well, and had put on weight; nothing abnormal was palpable in the abdomen. On April 26, 1949, after an opaque meal and follow-through, the radiologist (Dr. P. Tettmar) reported: "Nothing abnormal detected in the stomach and duodenum. In the follow-through the caecal region appears normal."

Case 2

A boy aged 15 walked into the out-patient department on February 16, 1949, giving a history of severe continuous abdominal pain for the last 48 hours, which had begun in the epigastrium and later shifted into the right iliac fossa. There was no nausea or vomiting. The bowels had been opened twice since the onset of the pain. Micturition was normal. There was no previous history of similar pain.

On examination his temperature was 98.4° F. (36.9° C.), pulse 100, and respirations 18. His tongue was dirty and foetor oris was present.

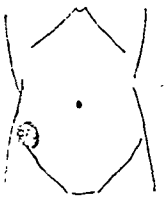

FIG. 2.—The position of the tender mass in Case 2.

An extremely tender mass was palpable in the right iliac fossa in the position shown in Fig. 2, with no resistance or rigidity or any other abnormality in the rest of the abdomen. Rectal examination revealed nothing abnormal. The chest and cardiovascular systems and the urine were normal. A provisional diagnosis of acute appendicitis was made and operation was performed under general anaesthesia.

The abdomen was opened through a Battle's incision. The mass previously felt externally was found to be an area of considerable thickening and acute inflammation, with oedema and petechial haemorrhages in the posterior wall of the caecum the size of a hen's egg. The area was fairly sharply demarcated from the rest of the bowel. The appendix, which was macroscopically normal apart from a few faecaliths, was removed. There were several firm glands with oedema in the ileo-caecal angle, and one of these was removed for microscopical examination. The abdomen was closed without drainage.

Post-operative Course.—Intramuscular penicillin, 100,000 units four-hourly, was given up to a total dosage of 6,000,000 units. A course of 32 g. of sulphamerazine was also given. On February 18 the white cells numbered 8,400 per c.mm. (polymorphs 75%, lymphocytes 20%, monocytes 4%, eosinophils 1%). On February 23 they numbered 4,000 per c.mm. (polymorphs 60%, lymphocytes 30%, monocytes 3%, eosinophils 7%). Stool examination revealed nothing abnormal.

The patient made an uneventful recovery and the wound healed by first intention. No abnormality was palpable in the abdomen a week after operation, and he was discharged from hospital on March 7.

The pathologist (Dr. W. W. Walther) reported: "The gland shows changes similar to those seen in glands draining areas of established inflammation. There is no evidence of tuberculosis. The appendix shows no evidence of acute inflammation."

The patient has since been seen at intervals, and has remained perfectly well and put on weight; nothing abnormal has been palpable in the abdomen. On April 28, after an opaque meal and follow-through, the radiologist (Dr. P. Tettmar) reported: "Normal stomach and duodenum. The caecum and ascending colon are well filled. No abnormality is seen. Normal rate of passage through the small intestine."

Comment

Two cases of acute phlegmonous caecitis are described. They are essentially similar to those previously reported in the literature as the diffuse and the circumscribed forms.

The condition, though rare, should be borne in mind in the differential diagnosis of acute appendicitis, from which it can be distinguished only by operation. The presence of a well-defined very tender mass in an apparently early case of acute appendicitis should give rise to a suspicion that it may be one of acute phlegmonous caecitis.

In both cases no harm followed appendicectomy and the caecitis resolved rapidly. The masses disappeared rather more quickly than in the cases of Spivack and Busch, probably because of chemotherapy. In the older literature a fatal outcome was recorded in some cases subjected to elaborate procedures such as resection, exteriorization, and lateral anastomosis. On the other hand, some cases recovered after appendicectomy only. Appendicectomy seems to be without special risk in these cases, and removal of the lesion must be regarded as unjustifiable, since resolution may be expected.

No further light is shed on the aetiology of the condition. The theory of abrasion of the mucous membrane, such as by a foreign body, followed by spreading inflammation of the bowel wall seems to be a reasonable one. The condition is probably essentially similar to the better-known acute phlegmonous gastritis. In this condition, also, radical surgery is no longer recommended (Maingot, 1948), but resolution may be expected with chemotherapy.

Medical Memoranda

An Unusual Case of Infectious Mononucleosis

The report by Eckstein and Peeney (1949) of a case of rectal haemorrhage associated with infectious mononucleosis prompts me to think that the following case is interesting enough to record. It is a case of infectious mononucleosis which presented with haemoptysis, subconjunctival haemorrhages, severe abdominal pain, and, later, meningitis.

Case Report

A previously healthy male farm-worker aged 17 was admitted to hospital in August of this year; he attributed his illness to a kick on the left side of his chest from a cow one week previously. He had no symptoms immediately following this occurrence, and was able to continue with his work normally. There had been no bruising of the chest wall.

On admission he gave a three-days history of feverishness and shivering attacks. At the onset of fever his legs felt weak and he developed a continuous central abdominal pain, which was sharp in character. One day later he had a slight unproductive cough and a constant severe lower retrosternal discomfort. From then onwards the abdominal pain became worse and was accompanied by vomiting. On the evening of admission he started to cough up blood, and at the same time his family noticed he had "red eyes." This was exactly seven days after his encounter with the cow. There was no past or family history of undue bleeding episodes.

On examination he was ill and apprehensive, though well built. The temperature was 103° F. (39.4° C.), pulse 120, and respirations 44 a minute. The tongue was furred and the fauces appeared normal. There was no anaemia, purpura, or icterus, and no glands were palpable. He was coughing up blood-stained sputum, and had bilateral subconjunctival haemorrhages covering the whole of each sclera.

He was afraid to move because of pain, and it was difficult to gauge whether it was the pain in the chest or in the abdomen that was the worst. However, there were no physical signs in the chest apart from the rapid respiration rate. The abdomen was held tight, and there was generalized guarding, with complaints of pain on palpation, particularly suprapubically. It was impossible to feel the spleen, but there was resonance over the left costal margin. Bowel sounds were present, and rectal examination was negative. There were no signs in the nervous and cardiovascular systems, and the blood pressure was 115/65 mm. Hg. The urine contained no albumin or sugar.

The chest was normal on radiography, and there were no fractured ribs. The haemoglobin was 95% (13.15 g. per 100 ml.), platelets 150,000 per c.mm., and white cells 13,500 per c.mm. (polymorphs 77%, lymphocytes 16%, and monocytes 7%). The blood urea was 70 mg. per 100 ml. The sputum, which was heavily blood-stained, contained no acid-fast bacilli.

Forty-eight hours after admission he was still very ill. The temperature was 100° F. (37.8° C.), and it was noted that the pulse was in the sixties. The vomiting was persistent, and he now had severe headache with neck stiffness. Lumbar puncture revealed opalescent fluid under increased pressure, containing 45 mg. of protein per 100 ml., a trace of globulin, and 102 cells per c.mm. Of these cells 60% were polymorphs and 40% lymphocytes. The chloride and sugar content was normal and the culture was sterile. Some small glands were palpable in the neck, axillae, and groins. A Paul–Bunnell heterophil antibody reaction showed agglutination at a dilution of 1 in 448. The spleen was never palpable and he developed no rash.

From this point onwards the patient improved. The headache and vomiting gradually eased up, and the abdominal pain and guarding subsided. He no longer coughed up blood. White blood counts after the initial one showed no abnormality or changes of glandular fever, but the heterophil antibody reaction revealed agglutination at a dilution of 1 in 896 a week after the first test. Lumbar puncture showed a gradual improvement, and the cells became practically all lymphocytes.

The patient made an uneventful recovery and was discharged from hospital three weeks after admission. He has reported again since, and is remarkably fit, with no abnormal signs.

Comment

On admission the case presented difficult problems. Not least was the history of a kick on the ribs a week previously. It seemed difficult to account for haemoptysis resulting after seven days from a kick that had caused no bruising of the skin, permitted him to continue normal work, and produced no fractured ribs or radiographic changes in the lungs. Similarly, it was difficult to explain the subconjunctival haemorrhages, particularly as his cough was mild and there had been no intense paroxysms of coughing before admission. The coincidence of the onset of meningeal signs with the development of superficial glandular enlargement prompted us to carry out a Paul–Bunnell test.

As to the mechanism of the various presenting symptoms, we can do no more than theorize. Pfeiffer (1889) in his original description recorded a slight irritating cough and pain in the lower abdomen in the majority of cases. The latter pain, in his experience, was nearly always felt midway between the umbilicus and the symphysis pubis. He suggested that swelling of the retrotracheal, retro-oesophageal, and mesenteric lymph glands was responsible.

Eckstein and Peeney have already referred to haemorrhagic manifestations as being among the rarer complications of infectious mononucleosis, and in their own case they demonstrated active bleeding from the mucous membrane of the bowel without any obvious cause.

It might be that this tendency to bleed accounted for the subconjunctival haemorrhages, the haemoptyses, and possibly the abdominal pain in the case here described, either of its own accord or in conjunction with glandular enlargement as envisaged by Pfeiffer.

The meningeal complications have already been described by Thelander and Shaw (1941).

I wish to express my thanks to Dr. T. H. G. Shore, consultant physician, for permission to publish this case.

H. T. N. SEARS, M.B., M.R.C.P.,
Senior Registrar, South Devon and East Cornwall Hospital, Plymouth.

Anginose Type of Glandular Fever Requiring Tracheotomy

Serious complications in the course of monocytic angina are uncommon. Tidy (1937), in an exhaustive review, states that "bronchopneumonia has caused one or two fatalities, but, apart from this, recovery is complete." Although Johnson (1944) described a severe case of anginose type in a 10-year-old negro boy, when "tracheotomy seemed almost necessary at times," a number of clinical accounts do not mention a case severe enough to warrant the operation (Fuller, 1941; Barber, 1941; Stevenson and Gow Brown, 1943; Smith and Shaw, 1945).

Case Report

Three weeks before admission to this hospital the patient, an agricultural student aged 22, had noticed a swelling of his neck, and at that time he had an enlargement of both tonsils, with pyrexia. Throat swabs were negative for diphtheria, and he was given a short course of sulphonamides. He did not improve, and he was admitted to an isolation hospital, where he received 12,000 units of diphtheria antitoxin on his first day, and 2,000,000 units of penicillin during the following week. His temperature remained up continuously, and although the faucial swelling was incised under local analgesia no pus was obtained. He became more dyspnoeic, and was transferred to this hospital with the diagnosis of acute leukaemia.

On admission on December 13, 1948, he had considerable oedema of the throat but no membrane formation or ulceration. Numerous glands in the cervical chain were enlarged and tender, but he had no general lymphadenopathy and his spleen was not palpable. He was very dyspnoeic and distressed, but not cyanosed.

The pathologist reported that the blood film was typical of glandular fever, with 79% mononuclear cells out of a total of 14,600 white cells. He was given N.A.B., 0.3 g., intravenously and three-hourly penicillin, with continuous intranasal oxygen, but in spite of this his condition deteriorated, and in the evening of the day of admission the necessity for tracheotomy was carefully considered in consultation with the laryngologist. We then decided against the operation, but during the night his condition became so grave that we felt it necessary to relieve his respiratory distress. At 5 a.m. on the following day tracheotomy was performed by Mr. John Roberts under local analgesia. The patient's condition improved immediately and his dyspnoea and distress rapidly lessened.

Three days after admission the Paul–Bunnell reaction was positive 1 in 2,224 (and to the same dilution after absorption). When repeated 10 days later this was positive at 1 in 256.

Four days after admission his blood count still showed an increase in mononuclear cells (75% of a total of 8,000 white cells). The blood Wassermann reaction and Kahn test were negative.

The tracheotomy tube was removed seven days after the operation and the wound healed satisfactorily. On December 29 (15 days after admission) the patient became unduly drowsy, and during that night he was restless and confused. The next day he became delirious, but, apart from a positive Kernig sign and mild neck rigidity, no localizing signs were found on examination of the central nervous system. Lumbar puncture was performed and the fluid was not under pressure; the cells were increased to 28 lymphocytes per c.mm., protein 70 mg. per 100 ml. (with increase of globulin), and chlorides 660 mg. per 100 ml.

This confusion and restlessness continued for some days, and later his general demeanour became vague and distant, with retardation of thought. These symptoms were transient, and a month later he had completely recovered. He was discharged on January 26, and when reviewed three months later was free from symptoms.

Comment

Tracheotomy in this case of severe mononucleosis was undoubtedly a life-saving measure, and the change in the condition of the patient after operation was remarkable. The administration of intravenous arsenicals was of no avail in reducing the faucial oedema.

A further interesting feature of the case was the occurrence of mild meningo-encephalitis during convalescence. Cerebrospinal manifestations of glandular fever are more widely recognized since Epstein and Dameshek (1931) first drew attention to them, and Landes *et al.* (1941) reported such a case in which the general behaviour was very similar to that of the patient described here.

Treatment of Bismuth Stomatitis with BAL (British Anti-lewisite)

BAL (British anti-lewisite, 2:3-dimercaptopropanol) has been soundly established clinically as an effective antidote in acute poisoning by the salts of gold, mercury, and arsenic, but a search of the literature has not revealed any report of its application in the complications of bismuth therapy. The following case illustrates the rapid action of BAL in acute bismuth stomatitis.

Case Report

A man aged 34 years attended the Special Department, Ashford Hospital, Middlesex, on January 19, 1948, for continuation of treatment for early generalized syphilis which he had acquired in Manchester 12 weeks previously. He had there received injections of arsphenamine (0.45 g.) and bismuth oxychloride (0.20 g.) at weekly intervals for two weeks.

On examination he had a healing indurated ulcerative erosion on the coronal sulcus near the frenal base, a generalized adenitis, and a fading maculo-papular rash limited to the trunk. There were no condylomata and no specific oral lesions, but a mild degree of pyorrhoea was present, and the second and third right upper molars were carious. The Wassermann and Kahn reactions were strongly positive.

His occupation (lorry driver) and hours of work precluded penicillin therapy for the time being, and the original treatment was therefore continued. After the importance of oral hygiene had been brought to his notice he decided to have dental treatment from his own dentist, whom he attended twice during the period January 19 to March 19, 1948, treatment on each occasion consisting of scaling and cleansing of the gum pockets. The carious molars were not extracted.

On March 18, 1948—i.e., at his ninth weekly attendance at the department and after the eleventh week of treatment—he showed some evidence of gingivitis. In addition, a faint blue line was present on the anterior lower gum margin adjoining the four lower incisors, and also on the upper gum margin behind the four upper incisors. Bismuth therapy was stopped, but weekly treatment with the arsenical was continued. A mouthwash containing 5% potassium chlorate was prescribed, and instructions given about the care of the mouth. Under this conservative treatment the gingivitis improved, but the blue line persisted. There was no albuminuria.

On April 7, 1948, he again attended his dentist, who repeated scaling and also extracted the two carious upper molars under local anaesthesia. On April 11 (four days later) he attended the department with all the signs of an acute bismuth stomatitis. There was considerable fetor, lividity, and turgid oedema of the alveolar tissues with submucosal haemorrhages, and extensive heavily marked blue lines on the upper and lower gum margins. Heavy bismuth deposits were seen on the buccal and lingual mucous membranes, the soft palate, and the left tonsil, and there was necrosis of the cavities of the extracted molars. A small painful bismuth-pigmented ulcer was present on the buccal mucous membrane adjoining the cavity of the third right upper molar, and he had had a painful, tender bilateral submaxillary adenitis. There was slight pyrexia (99.2° F. : 37.3° C.), oliguria was present, the urine showed a cloud of albumin, and on microscopic examination a few red cells and epithelial casts were seen. The differential blood count showed a mild leucopenia (5,000 per c.mm.) and thrombocytopenia (90,000 per c.mm.). Dark-field examination of the detritus of the ulcer on the buccal mucous membrane revealed masses of *Treponema vincenti* and *Fusobacteria plauti-vincenti*.

Arsphenamine therapy was stopped, and the patient was admitted to hospital. The presence of organisms of fuso-spirillary type in the mouth was an indication for penicillin, but this was withheld because it was not known if BAL had any effect on the action of penicillin, and in addition the case offered an excellent opportunity to study the unaided action of BAL. Treatment with BAL was begun at once, the preparation used consisting of a 5% solution of 2:3-dimercaptopropanol in arachis oil containing 10% benzyl benzoate. He was given 2 ml. (by intramuscular injection into the gluteal region) thrice daily for two days, twice daily for four days, and once daily for four days, after which (i.e., 14 days after the onset of the complication and 10 days after beginning treatment with BAL) the condition had completely resolved, except for residual alveolar lividity, painful lingual oedema, and intense salivation. The bismuth deposits and the blue lines had vanished.

Local treatment of the complication was entirely palliative, and consisted of frequent cleansing of the teeth, gum massage, and use of a mouthwash containing ¼% zinc chloride.

Clinical response to BAL was evident almost from the first day of treatment, and improvement was continuous and rapid. On the seventh day of therapy the urine was albumin-free and microscopically showed no abnormality, and the temperature and differential blood count were normal. Fourteen days after onset of the stomatitis he was discharged from hospital, and seven days later arsphenamine therapy was resumed.

The toxic reactions to BAL were comparatively mild. The patient complained of headache, nausea, a burning sensation in the eyes, lacrimation, and some local pain at the site of injection. Salivation and painful lingual oedema persisted for several days after cessation of therapy. The blood pressure remained constant throughout.

A. A. M. Reekie, M.B., B.Ch.,
Physician-in-Charge, Special Department, Prince of Wales's General Hospital, London; Ashford Hospital, Middlesex, etc.

The Woods School, which is a school for mentally and physically retarded children at Langhorne, Pennsylvania, U.S.A., has been given by its founder, Mrs. W. M. Hare, to a board of trustees. The school was founded in 1913 with the aim of teaching children with behaviour problems and those with reading or speech difficulties to meet the problems of everyday life.

Reviews

OPERATIVE AND LABORATORY OBSTETRICS

Die Geburtshilflichen Operationen. By Professor H. Martius. Sixth edition. (Pp. 287; illustrated. M. 15.60.) Stuttgart: Georg Thieme.

Greffe Ovarienne Intra-oculaire chez la Lapine Castrée: Application au Diagnostic de la Gestation. By J. Vors. (Pp. 71. No price.) Paris: Vigot Frères.

Morphologie et Histologie des Corpsprogestatifs et Gestatifs (Corps Jaunes) de l'Ovaire Féminin. By G. Dubreuil and M. Rivière. (Pp. 102; illustrated. No price.) Paris: Vigot Frères.

Martius's *Obstetrical Operations*, first published in 1934, has now reached its sixth edition, and its popularity is well deserved. In 275 pages, with the help of 281 illustrations, Martius has given a comprehensive description of the art of operative obstetrics. The text is practical and the style is dogmatic, so that the reader is never in doubt of the author's meaning The subdivisions are excellent, and the arrangement of headings allows the salient features to be picked out without difficulty. The illustrations show Martius's usual judgment and ingenuity, and particular mention must be made of those depicting episiotomy. Although many of the diagrams are copied from old favourites, there is not always acknowledgment; it is well known that obstetrical illustrations are copied from book to book, and it is a matter of regret that the originators of some of the classical diagrams have been forgotten.

Like Pater in his essay on da Vinci, with its subtle emphasis on La Gioconda, Martius contrives to create the same emphasis on forceps delivery, and his description has seldom been equalled. Willet's forceps are mentioned, but there is no recognition of the modern English methods employed in breech delivery. Lovsett's manœuvre is not described, nor is the Drew Smythe catheter. The German classification of flexed and deflexed vertices has never been favoured in Great Britain, though it is found in the text-book of Jellett and Madill. The practical application of this method should not be completely ignored. It is probable that the work will be translated and published in America, and it is hoped that Martius will incorporate in the next edition the valuable contributions to operative obstetrics which have been made there and in Great Britain.

Grafting of tissues into the anterior chamber of the eye has been practised for many years, and important work has been done with this technique, particularly by Allen and Preist and by Markee. Vors describes in detail the transplantation of a homologous graft from a young rabbit into the anterior chamber of a castrated doe of adult age. The reaction of the graft to injected gonadotrophins can be accurately studied, and the author suggests that the method can be used to replace the Friedman test for the diagnosis of pregnancy. It is possible that the technique will be widely used in the future, and it might be employed to determine the concentration of gonadotrophins in the blood and urine of patients suffering from endocrine diseases.

Dubreuil and Rivière's short publication gives a general account of the histology of the corpus luteum of pregnancy and of the corpus luteum of menstruation. The authors endeavour to distinguish between the two types of corpora lutea in a way which is not altogether convincing. A valuable description of the cystic forms of the corpus luteum of pregnancy is given, and the retrogressive forms are described with some accuracy. The views of the authors on the colloid bodies are not likely to be accepted by many who have worked on the corpus luteum. The references are good, but it cannot be said that the publication is outstanding.

WILFRED SHAW.

PUBLIC HEALTH IN THE U.S.A.

Public Health in the World To-day. Edited by James S. Simmons. With foreword by James Conant. (Pp. 332. $5 or £1 7s. 6d.) Massachusetts: Harvard University Press. London: Geoffrey Cumberlege. 1949.

During 1947–8 a series of public health forums conducted by distinguished guest speakers was added to the regular curriculum of the Harvard School of Public Health. The papers presented at 22 such conferences are reproduced in this book. There is a foreword by the President of Harvard University and an introduction by James Stevens Simmons, who edited the volume.

The book, like the papers on which it is based, is intended primarily for our American colleagues, and it goes without saying that the need it will meet on this side of the Atlantic is entirely different from that in the United States. For the professional reader, or the intelligent non-medical reader in the States, the work provides a readable factual account of many aspects of American public health and its history and objectives—subjects which will obviously attract only a small number of readers here. Were these the only topics discussed, the book's main purpose in England would be to furnish a means of comparing American problems and the American outlook with our own. From this standpoint the English reader will be left in no doubt that there are big differences in matters of detail between the two countries, notwithstanding a close similarity of fundamental outlook. This is instanced by the relatively greater emphasis given in the U.S.A. to statistical researches into the need for medical care, the place of voluntary agencies, and the statistical evaluation of the efficiency of health programmes.

On the other hand, papers from the pens of C. Winslow, Professor Emeritus of Public Health at Yale, Hugh J. Morgan, and Louis I. Dublin—discussing respectively the evolution of public health and its objectives, public health, preventive medicine, and the practising physician, and public health and the diseases of old age—bring out resemblances between the evolution of public health thought, current practical problems, and aspirations for the future of preventive medicine on both sides of the Atlantic.

The topics covered by this stimulating symposium are too diverse to permit of any short summary of their scope, but chapters on subjects like world health, and public health problems connected with aviation and the atomic era, clearly have an interest which transcends national boundaries.

This is not a book which most people will read from cover to cover, at all events in this country. But almost every reader will find sections of great interest—some factual, and others somewhat philosophical. For the Englishman who is already acquainted with the public health services of the United States the book will have a special appeal, as it will also for teachers of preventive and social medicine and for the reader who wishes to have an American account of certain aspects of international medicine. The book should find a place on the shelves of medical libraries because of the facts, ideas, and appraisals it contains.

FRED GRUNDY.

STUDY IN NEUROSIS

The Neurosis of Man. By Trigant Burrow, M.D., Ph.D. (Pp. 428; illustrated. £1 8s.) London: Routledge and Kegan Paul. 1949.

This is not a book for holiday reading and it is difficult to understand even by patient study. I agree with a criticism of his views which the author himself quotes (p. 19): "It is not only that I find them hard to read because of the unfamiliar vocabulary and locutions; . . . I experience a positive feeling of opposition every time I read his work."

It is stated by the publishers that the book "sets aside discussion and opinion respecting human maladjustments and introduces a much-needed science of human relations." But the first few chapters are full of dogmatisms without shadow of proof or clinical illustration—indeed, the views are described as "a development away from clinical psychiatry."

The attitude adopted in the book may be illustrated by a few quotations. The author says (p. xiv): "In a moment of evident vexation, Freud once remarked to a mutual colleague of ours, 'Does Burrow think he is going to cure the world?' to which my unequivocal reply was, 'I most certainly do.'" "Our whole purpose . . . was to discredit all there was of man's behaviour prepossessions—all the inherited mental and social constructions habitually cherished by us—and to build anew." And on p. xvii: "It is a supreme effort to put into the hands of man what belongs in the hands of man, and not in the hands of a few absurd mental healers."

Some basic principles of his study are fully justified—the belief in the "oneness" of human life, for example, which he describes as its most powerful instinct. Again, he considers that attention is not an isolated mental function but a reaction of the whole organism to the environment by which it performs its "instinctive" functions. His effort to carry the reader back to biological principles is also welcome, for he studies man as such, especially in his primitive relations and reactions to the environment. Hence the author's criticism of Freud in his individual analysis, and his resort to "phylo-analysis—the analysis of the psycho-organism of man." Many mistakes in psychology and psychopathology could have been avoided if we had kept "close to nature" and based our psychological speculations on biological principles. I am also pleased to see his criticism of social standards of "right" and "wrong" as our infallible guide to human conduct. But Freud has already made us aware of the danger of blindly accepting "super-ego" standards which may do violence to our own nature and so cause neurosis.

The author refutes the idea that abnormality consists in the fact that the "patient does not think and feel as the community thinks and feels" (p. 232) on the grounds that the community itself which passes such judgment is only pseudo-normal. For this he substitutes the idea that the neurosis of man consists in a "maladaptation in the functions of man's brain in respect to its environment."

The author bases his concept of the organism reaction to life on what he terms "cotension," which is "the neurodynamic relation of organism to environment as it exists natively and indifferentiated within the cerebro-sympathetic system" and "relates the organism kinesthetically to the outer world" (p. 216). Cotension, for instance, enables us to perform the extremely complicated process of balancing with our eyes closed. Just as the skeleton is the organism's structural framework, so is cotension the organism's functional support (p. 247). But this primary tensional pattern has been superseded by ditension, one of the main causes of which appears to be the imposition of social patterns upon the individual, with its false dichotomy of "right" and "wrong" giving rise to a pseudo-identity or "I"-persona, so that it is difficult to recall the original submerged pattern. The real conflict in man is between the "I"-persona and this organism. Cotension means integration, co-ordination, and health, ditension means disintegration, disorder, and disease (p. 247). Neurosis appears to consist in the denial of this primitive adaptation of man to his environment in favour of the "I"-persona. This is not a problem of this or that individual, but a problem of man as such, and requires the reorientation of all our values, moral as well as social.

In practice the author protests against the teaching of parents who have been "brought up in the meshes of moralistic dichotomy," and who therefore inculcate in the child the vacillating law and vague shibboleths we call right (p. 83). Instead of this he proposes to "inculcate in the child a sense of its relation as an organism to its environment."

J. A. HADFIELD.

FUNCTIONAL PATHOLOGY

Die Permeabilitätspathologie. By Professor Hans Eppinger. (Pp. 755; 145 figures; unbound, £7 2s. 6d.; bound £7 7s.) Vienna: Springer. 1949.

According to Eppinger the general theory of pathology requires three concepts—cellular pathology, humoral pathology, and permeability pathology, which is the logical completion of the other two. For most pathologists, at any rate in the English-speaking world, the concepts of cellular and humoral pathology have lost their importance, the phenomena which gave rise to them having been vastly extended and regrouped. Humoral pathology has been transmuted into a separate group of disciplines, including physical chemistry, serology, and haematology, and the cell is now thought of as a complex biochemical system rather than as a little ball with a smaller one inside it. Modern pathologists are perhaps more physiological in outlook than they themselves realize, for they regard the histological section as simply a snapshot of one phase in a series of processes, clinical or experimental; they are all in varying degree functionalists, and the boundaries between cellular and humoral pathology have vanished.

Eppinger's book is a discussion of the role of membranes in disease, of physical chemistry applied to pathology. Most of it is concerned with general pathology, and among the many phenomena discussed are tissue fluids and cell metabolism, electrical phenomena at cell surfaces, oedema, albuminuria, histamine poisoning, and anaphylaxis. The last third of the book describes the special pathology of the kidneys, liver, and circulatory and alimentary systems.

The author's outlook is that of the nineteenth century, and the giants of German pathology so fascinate him that he neglects his contemporaries. The references are often very old, and the work of the past decade is hardly noticed. Much miscellaneous information is given, but in the main the book is platitudinous and extremely verbose. This is not the fault of the German language, which can be as crisp and clear as the best English; it is due rather to looseness of thought that might possibly be put down to advancing years or the stress of war. The book may well serve as a reminder that even the ablest writers pass the meridian, and that a time comes when it is best to be silent. The most attractive feature of the book is the author's affection for Rokitansky; in this many pathologists will be at one with him.

RAYMOND WHITEHEAD.

THE CHEMISTRY OF FOODSTUFFS

Elements of Food Biochemistry. By William H. Peterson, Ph.D., John T. Skinner, Ph.D., and Frank M. Strong, Ph.D. (Pp. 259; 34 figures. 21s.) London and New York: Staples Press. 1949.

In nutrition, you cannot be said to have your cake until you have eaten it. Many popular works on food stop short at the mouth of the consumer, but the purpose of this book by the Professor of Biochemistry and his colleague at the University of Wisconsin, and Dr. Skinner of the Kentucky Agricultural Experiment Station, is "to emphasize the chemistry of the constituents of food and the chemical changes that these constituents undergo in the process of metabolism." The exposition throughout is clear and precise, and a large amount of information is neatly arranged and tabulated in a relatively small volume. Separate chapters describe each chief class of nutrient; economic as well as dietetic factors are considered; important chemical reactions are specified; and each section is equipped with a short bibliography and a list of questions that will be helpful to busy examiners.

The figures are mostly selected from previously published photomicrographs of crystalline nutrients. While these have their value in showing the student that the substances have been isolated and "really exist," none of the illustrations gives any indication of the scale of magnification—the budding yeast cells in Chapter II are nearly as large as the nutritionally deficient rat, of unspecified age or weight, in Chapter VI.

In a book designed to emphasize the dynamic as well as the static aspect of food chemistry no mention is made of Frazer's important work on the mechanism of fat absorption, nor the use of tracer isotopes in metabolic studies, nor the applications of chromatography and microbiological assay to the estimation of the individual amino-acids and vitamins in the blood. This may be related to the fact that the bibliographical references do not go beyond 1942. The appendix of 22 pages contains extensive tabulations of the composition of foods, and includes valuable hitherto uncompiled data for the vitamins of the B group, based on work done in the Biochemical Laboratories at the University of Wisconsin.

W. R. FEARON.

The departments of Child Health and Medical Illustration, Guy's Hospital, are to be congratulated on the design of a card depicting breathing exercises for children from 5 to 10 years of age (*Special Breathing Exercises for Children*; 9d. each; Guy's Hospital, London). The card is constructed so that it can be stood on a mantelpiece to catch the child's attention. The amusing illustrations will undoubtedly attract the notice of all who enter the room, the brief directions are explicit, and the exercises entertaining. It still remains doubtful, however, how much good (or harm) breathing against resistance can do, so that the balloon exercise might with advantage be omitted.

The greater part of Dr. C. Berg's *Clinical Psychology* (pp. 503; £1 5s.; London: Allen and Unwin, 1948) is made up of graphic accounts of cases in the process of analysis. The theoretical background is substantially orthodoxly Freudian in character, but the more recent theories of depression, destructive impulses, and introjection-projection mechanisms in early childhood are not given sufficient weight. The complex pre-oedipal life of the child is very sketchily conveyed. This is a serious omission, as it would have enhanced the author's thesis of the tenuous frontiers separating psychosis from neurosis. The treatment section is very fair, and Dr. Berg adopts the more catholic technique of restrained interpretation as against the early sallies into interpretation by the more advanced or Kleinian wing of Freudian psychopathology. For those embarking on a psychiatric career this book is well worthy of study, and by the experienced analyst it will be read as a stimulus to lively discussion on points of technique and theory.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 26 1949

GENERAL PRACTITIONERS' REMUNERATION

Rejecting the claim of general practitioners for higher total remuneration, the Secretary of the Ministry of Health argues,[1] first, that in view of the amount now being paid "no reasonable case can be made for any increase," and, secondly, that the economic state of the country prohibits an increase at present. The profession's claims were set out in a report[2] prepared by the General Medical Services Committee and approved by the Special Conference of Representatives of Local Medical Committees on March 3. They were sent to the Ministry on March 4, and on March 29 the Representative Body supported them.

The Ministry meanwhile sought information from executive councils on how much had been paid to general practitioners. It was unable to present the results of its inquiry until August 18, and on September 23 found itself ready to discuss them with a deputation from the General Medical Services Committee. At that meeting the deputation drew attention to a number of inaccuracies in the document, and the Ministry admitted them; some seemed to be mistakes in arithmetic; others were due to disregard of one or two highly relevant factors. The Ministry promised to correct its mistakes, but that, in the Ministry's words,[3] "involved a good deal of research." Therefore on October 27 the Conference of Representatives of Local Medical Committees, after deploring the Ministry's delay in the matter, resolved that, as the central pool could be properly calculated without redrafting the Ministry's document, the calculation should now be made in agreement with the representatives of the general practitioners. Sir William Douglas's letter is the response to this demand.

The size of the central pool depends in the first place on the Spens recommendations, which were formulated in terms of the 1939 value of money, and the Ministry agreed with the B.M.A. that the pool, in those terms, should be £31.24 million. In order to convert this sum into one that reflects the higher cost of living to-day the Ministry assumed that practice expenses—taken as 40% of gross remuneration—have increased by 55%, and it added 20% (determined in 1946) to the net income. The betterment factor on gross incomes compounded from these calculations is 34%, and this brings the pool up to £41.46 million. Since the population of the country was estimated to have increased since 1939 by 3%, £1.24 million was added, making £42.7 million. The profession agreed with the Ministry that 95% of the population might be expected to use the Service, so the pool was reduced to £40.57 million. When the present population of the country is accounted for, the central pool for the financial year 1949–50 becomes £41.3 million.

An increase of 34% clearly does not reflect the change in the value of money since 1939. The B.M.A. took the advice of an expert economist, who concluded[4] that the cost of living of the professional classes had in 1948 risen by 85% above the 1939 cost. In putting its claim before the Ministry the B.M.A. argued that it was justifiable to ask for an increase of 70%, and, after other minor adjustments had been made, the Association's claim differed from the Ministry's estimated central pool by about £16.5 million.

The Ministry has tried to bridge this gap from both ends, though the structure does not quite meet in the middle. In the first place it has added to the central pool of £41.3 million the sum of £7.5 million derived from various additional sources such as payments for maternity medical services, provision of drugs, training assistants, and the Exchequer superannuation contribution. It thus brings the total amount to be paid to general practitioners in the financial year 1949–50 up to the sum of £48.8 million. Working from the other end, and assuming that there are 18,936 principals in general practice instead of the 20,000 estimated by the B.M.A., the Ministry has calculated the central pool in accordance with the Association's betterment factor of 70% to be £53.5 million. The difference between the two totals is £4.7 million, or about two shillings on the capitation fee. The Ministry points out that there are some other sources of income derived from the Exchequer to be considered also, such as payments for dental anaesthetics and work done for local authorities.

The General Medical Services Committee will meet on December 1 to consider these figures, and no doubt its members are aware, as the Minister of Health is said to be, of the "vital national need to avoid any unjustified raising of remuneration in any field." Had the same figures been discussed six months ago—as they would have been if the Ministry had been less dilatory—a decision could more simply have been made. Again, the situation may be easier—or more difficult—in six months' time. But on December 1 the committee will have a harder choice before it than the Minister's opinion quoted above would suggest. For it is not a

question of an "unjustified" increase being claimed but one that is related to the Spens Report, which the Government accepted in principle.

UNDERNUTRITION IN EUROPE

Opportunity to study the effects of prolonged undernutrition on the human body was all too frequent in Europe during and after the war, and several observers have published books on the subject. The findings of Brull and his assistants[1] are particularly interesting, for they were obtained by detailed studies on the general civilian population of all age groups over 14 years during the German occupation of Belgium. Their work is selective in that the individuals investigated were those who presented themselves at the Medical Clinic of the University of Liége. They undertook also special studies of small groups of school-children and heavy workers. Body weights were reduced by about 12% by the middle of May, 1941. During the following 12 months a further slight fall (12.9%) was observed. Between May, 1942, and the end of January, 1944, body weights rose slowly and were 7.8% below normal on the latter date. Disorganization of transport in the spring of 1944 caused a sharp decline to the level of May, 1941. In spite of these weight losses plasma-protein concentrations remained within the normal range: the mean value (3,137 observations) was 6.99 g. per 100 ml. Blood pressure fell (systolic and diastolic) on an average by 20 mm. Hg for a weight loss of 10 kg. There was no significant fall in haemoglobin concentrations between January, 1940, and October, 1944 (9,794 patients). In the adolescent group normal weights and heights were recorded in February–April, 1942: no signs of anaemia or of avitaminosis were found, but a slight fall in plasma-protein concentration, blood cholesterol, and phospholipids was noted. The heavy workers lost weight, but this was not sufficient to bring the level below that taken as the lower limit of normal for the age and height of the individual. This relatively small loss of weight was due to the effect of food grown in allotments or obtained through the black market. Famine oedema occurred mostly in males over the age of 40, but its frequency in the general population has not been recorded. Oedema was present even when the plasma-protein concentration was above that regarded as the "oedema level." The amounts of vitamins A, B_1, and C in the blood were estimated, and no signs of avitaminosis were found. As might be expected, the incidence of bone demineralization was extremely low: among 30,000 patients, five had osteoporosis which could be attributed to calcium and phosphorus deficiencies. Four of the five were females over 59 years of age; one case occurred in a young man who had suffered from severe undernutrition. Gastro-duodenal ulceration increased in frequency during the first year of the occupation; this was attributed to emotional factors.

Simonart[2] investigated undernutrition in prisoners in Louvain Gaol. As the reduced ration could not be supplemented, the effects of known diets could be observed and the results of various therapeutic measures assayed with accuracy. The classical work of Benedict on starvation was amply confirmed. Simonart, however, studied in some detail the role of vitamin B_1 (aneurin) in water and carbohydrate metabolism. Apparently the intake of this vitamin was below the normal requirements, for signs and symptoms of beriberi appeared: he found that intravenous injections of aneurin not only increased muscular power but when oedema was present they assisted the kidneys to eliminate water. He confirmed Brull's finding that famine oedema is not related to the plasma-protein concentration. In several of his cases the globulin fraction of the plasma protein was increased above normal, but a constant finding was that the serum albumin was reduced. When refeeding was possible, he was of the opinion that vitamin B_1 increased the rate of albumin regeneration. An interesting observation was that the blood pyruvate was raised; he related this to the vitamin B_1 deficiency. This is important for the light it throws on the intermediary metabolism of carbohydrate in man. Most of Simonart's clinical observations agree with those made by Brull and his colleagues, but the signs and symptoms were much more severe in the Louvain patients. Sudden heart failure was the usual cause of death. Coma, indistinguishable from diabetic coma, occurred and was treated by infusions of glucose solution.

The condition of the Louvain prisoners was intermediate between the undernutrition observed by Brull and the extreme emaciation of the majority of the 296 patients who came under the care of a team of Swiss workers headed by Hottinger.[3] Body-weight losses of 40–50% were common in this group. The similarity between the clinical conditions found and those described by Mollison[4] in the inmates of the Bergen-Belsen concentration camp is close. Many of the patients had skin infections, typhus and typhoid fevers, or tuberculosis. The Swiss workers have provided much information about the value of different methods of treating these starved persons. They also report in detail the pathological findings in 53 necropsies. These records are accompanied by a critical survey of the literature on every aspect of the starvation state. They began treatment with a "transition" diet, which was

given in small frequent meals (5–6 per day). This diet was rich in protein and contained only a small amount of fermentable carbohydrate and of fat. It amounted to approximately 2,500 calories per day. After 4–5 days a diet containing 4,500–5,000 calories was given: this, too, was rich in protein, low in fat, and contained little fermentable sugar in its carbohydrate fraction. Cases of anaemia and hypoproteinaemia were treated with blood transfusions and plasma infusions. Where necessary, cardiac weakness was treated with the usual cardiac stimulants. As avitaminoses were common, vitamin supplements were given. These provided vitamins A, B complex, C, D, and E (tocopherol) in quantities equal to about double the daily requirement of a normal adult.

INFECTION IN THE NURSERY

With the increasing demand for maternity beds the medical and nursing staffs of maternity departments have a heavy responsibility to ensure that proper precautions are taken to protect both mother and baby against the risk of infection. The newborn baby has little capacity to withstand infection even by bacteria of low pathogenicity, and a loose stool or pimple on the skin may be the danger signal of an outbreak that will cause havoc in the nursery, particularly among premature and artificially fed infants. However, most of the infections, the incidence of which has varied in recent reports from 3 to 30%, are relatively mild and, as Dr. Janet D. Roscoe pointed out in last week's *Journal* (p. 1144), affect principally the eyes ("sticky" eye) and the skin, with the staphylococcus as the most frequently found organism. Coagulase-positive staphylococci are common in the maternity nursery; they have been found in the noses of half the staff and 80–90% of the babies, in the throats and faeces of 20–50% of the infants, and in the dust and on bottles, towels, napkins, and the like. What is not yet known is whether these potentially pathogenic staphylococci vary in their capacity to initiate infection. Serological and phage typing of the staphylococcus may help to give the answer, and already there is some evidence that certain phage types are particularly associated with outbreaks of pemphigus.[1] Certainly when an outbreak of pemphigus is bacteriologically investigated it is usual to find a widespread dissemination of the infecting type, but more studies are needed on the distribution and types of staphylococci in non-epidemic periods. It might well happen that one type will establish itself in the nursery in the absence of infection, and this is likely to occur when penicillin is being used indiscriminately, with the emergence of a penicillin-resistant strain. Should an infant's skin be made more susceptible to attack by the use of a rough towel or cheap soap or the conjunctiva by prophylactic silver nitrate, the prevalent staphylococcus becomes the infecting strain and may thus be wrongly identified as an "epidemic" type. It is possible that invasiveness—the power to attack healthy tissues—is particularly associated with certain types of the staphylococcus, as seems to be the case with the pneumococcus. It has already emerged that the capacity to produce enterotoxin is limited to two or three types of the staphylococcus—in particular types 6/47 and 42D[2]; but, as Dr. G. Martyn demonstrated in a paper appearing in last week's *Journal* (p. 1146), the mere finding of enterotoxic staphylococci in the faeces of infants does not mean that these types are aetiologically associated with infantile enteritis.

With the coliform group of organisms, too, there may be "epidemic" and "endemic" types, for two serological types of *Bact. coli* have been recently found in association with outbreaks of gastro-enteritis. The studies of Drs. A. M. McFarlan, P. B. Crone, and G. H. Tee, whose paper on the normal bacterial flora in infancy also appeared in last week's issue (p. 1140), indicate that the opportunities for the spread of coliform organisms, as shown by their presence in the throat, are much greater in artificially fed infants, among which outbreaks of diarrhoea or vomiting mostly occur, than in breast-fed babies. However, the value of such studies would be considerably enhanced if the staphylococci, coliform organisms, or faecal streptococci found on the mucous membranes could be precisely identified by serological or phage typing, so that the introduction of a new strain, perhaps with pathogenic properties, could be recognized and related to any infective episode that might occur.

Meanwhile the wide variation in the amount of nursery infection suggests that conditions could be improved in many maternity departments. Pupil midwives and nursery nurses need to be taught that babies require very different handling from adults, and they should be instructed in the dangers of cross-infection in hospitals and the means of controlling it, as outlined in the Medical Research Council's Memorandum[3] on the subject. The new Ministry of Health film entitled "Tracing the Spread of Infection" would be a useful introduction to such instruction. The use of small units of four to six beds which can be filled within 1–2 days and cleaned between each new "intake" may also be recommended as a method of reducing hospital cross-infection[4] and has other advantages. The large often overcrowded nursery is fast becoming an anachronism, while the need for special units for premature babies is being increasingly recognized. Above all, breast-feeding with the minimum of supplementary feeds should be the objective in all maternity departments.

INTRAVENOUS PROCAINE

Although procaine was discovered by Einhorn in 1905 its intravenous use is comparatively recent, for standard textbooks on anaesthesia have pointed out for over 40 years that delirium, convulsions, and death might result from the injection of procaine directly into the vascular system. This is indeed true if a large dose is rapidly given, as many have testified since the drug was introduced. The first deliberate intravascular injection appears to have been given by Leriche and Fontaine[1] in 1935 for the treatment of endarteritis obliterans. During the war, following Lundy's observation that it relieved the pruritus of jaundice,[2] intravenous procaine was used to secure analgesia for the dressing of burns and wounds, and it was observed that it caused far less respiratory depression than morphine. It soon became clear that comparatively large amounts of procaine could be administered intravenously with safety if given slowly. The drug has been used in the last few years for a surprisingly large number of clinical conditions, ranging from "allergy to angina and pruritus to parturition."[3] There is no doubt that intravenous procaine can relieve pain without causing loss of consciousness or respiratory depression; this makes the drug particularly useful in the management of traumatic, inflammatory, and spastic conditions, and for the relief of pain in peripheral vascular disease. Not only is it analgesic but it causes peripheral vasodilatation. Fraser[4] and Mackersie[5] have supplemented thiopentone anaesthesia with intravenous procaine, and other workers have used it, with apparent success, to obtain analgesia in labour.[6-8]

There is evidence that cardiac irritability is reduced by procaine, which, in fact, is nearly as active as quinidine in this respect. It is now the practice of some anaesthetists to give procaine in an intravenous drip throughout thoracic operations because it not only prevents cardiac arrhythmias but abolishes the cough reflex, minimizes bronchospasm, relieves post-operative pain for several hours, and enables adequate analgesia to be maintained with smaller amounts of other agents.[5 9] Siddons and Landau[10] have recently used it in the treatment of post-operative atelectasis; the patient is given an intravenous injection which enables him to cough violently without pain. In a paper appearing elsewhere in this issue Dr. H. E. Pooler refers to the high incidence of pulmonary complications after operations on the upper abdomen. He used procaine by intravenous drip as a method of maintaining the vital capacity after an operation at its pre-operation level, and concluded that though this greatly relieved pain the increase in vital capacity was comparatively small. Good results with intravenous procaine have been reported in allergic states, such as serum sickness, drug and antibiotic sensitization reactions, asthma, and urticaria, though it has not been shown pharmacologically that it possesses an antihistaminic action.

Great care must be exercised in administering procaine intravenously owing to the danger of convulsions and respiratory failure, and facilities for the treatment of these complications should be at hand. Graubard and his coworkers[11] recommend a dose of 4 mg. of procaine per kilogramme of body weight; this is injected in a 0.1–0.2% solution over a period of 20 minutes. This calculated dose is usually tolerated without toxic effects. The rapid administration of a 1% solution is sometimes used for the treatment of cardiac arrhythmias or status asthmaticus. If convulsions occur as the result of the injection they are treated with an intravenous barbiturate such as thiopentone, and circulatory and respiratory depression with ephedrine or *d*-desoxyephedrine and controlled respiration.

TOTAL CYSTECTOMY

Tumours of the bladder vary considerably in their malignancy, but even benign growths tend to undergo malignant change if inadequately treated. While local removal or destruction is satisfactory in some cases, there are many in which the size, multiplicity, or situation of the growths makes more radical treatment necessary. In a number of these cases the tumours are of low-grade malignancy and can be removed in their entirety by excision of the bladder. The need for diversion of the urinary stream before cystectomy no doubt partly explains why this operation has not found greater favour with surgeons in the past. With cutaneous ureterostomy a double urinary fistula is an unpleasant necessity, and the method of choice is transplantation of the ureters into the colon. The fear of ascending infection of the kidneys is largely unfounded, for, as Ferris and Priestley[1] have pointed out, a kidney which has good drainage whether to the bowel or the skin seldom becomes seriously infected except by the blood stream. Once the technique of transplantation can be successfully mastered the removal of the bladder presents a less serious problem, unless there is gross infiltration. Ferris and Priestley reported a fatality rate of 13% in 119 cases treated in hospital; over a 10-year period they have reduced the number of stages of the procedure from three to two, and finally, as they acquired familiarity with the operation, to one in selected cases. They have adopted the intraperitoneal rather than the safer extraperitoneal operation, since they found that it could be accomplished with reasonable expectation that leakage at the site of anastomosis would not occur. The relative safety of the extraperitoneal operation has been pointed out by Riches,[2] who reported a fatality rate of 8.3% in 60 cases in which transplantation was carried out; in 49 of these the operation was undertaken for new growth of the bladder or urethra.

The results of cystectomy were further improved by Jewett and Lewis's[3] finding that curability in deeply infiltrating tumours was very low, but that it increased when only the submucosa or the superficial muscle layer was infiltrated. They also showed that the degree of infiltration could be assessed before operation by bimanual examination under full anaesthesia—the detection of a rubbery or stony mass almost invariably indicating deep infiltration. This is the most important single clinical method of distinguishing between the cases in which operative treatment is

5 *Proc. R. Soc. Med.*, 1933, 26, 1214.

likely to be successful and those in which the growth will recur after total cystectomy. Sworn[4] has recently reported in this *Journal* six cases in which he performed cystectomy with no operative mortality; he transplanted the ureter by embedding it in the bowel wall in continuity before its division. This method was described by Winsbury White[5] in 1933; it has the advantage of establishing firm union between ureter and bowel before either is opened, but it is no less liable to produce constriction at the anastomosis than other methods, and late results must be judged by renal function and by the appearance or otherwise of pelvic dilatation. Sworn's second case, in which the growth was fixed to the pelvic wall, would have been included in the unsuitable group by Jewett and Lewis, and the early recurrence was to be expected. It is a sign of progress that more surgeons are successfully undertaking this extensive operation; there would be even greater cause for satisfaction if more patients were examined with the cystoscope at an early stage of the disease, when such a formidable undertaking is less likely to be necessary.

CANCER AMONG DIABETICS

The proportion of diabetics who have cancer has been placed at from 1–9% by various workers, but the evidence on which their findings have been based has not been conclusive. The problem of discovering whether cancer occurs more frequently among diabetic patients than among the rest of the population appears to be quite simple at first sight, but objections can be raised to several procedures that have been used in attempts to produce a solution. Mortality data are readily available, but the use of cancer deaths to measure the association with diabetes may be unreliable owing to the absence of concurrent conditions on the death certificates. With an accepted major cause of death such as cancer the physician may not report associated conditions, especially if they did not contribute to death. It seems unlikely, therefore, that a study of the associated causes of death on death certificates will lead to an unbiased answer. Objections to the use of clinical data can be raised on several grounds, but chiefly because the patients may not be representative of the general population of diabetics.

Jacobson[1] has reviewed the work of previous investigators and has analysed the data collected by the National Health Survey of the urban population of the United States during the winter of 1935–6. This survey included 2,500,000 persons, among whom there were 2,912 males and 5,278 females (aged 25 and over) reported as diabetic. Cancer was recorded for 18, or 0.6%, of the diabetic males and 37, or 0.7%, of the females. The diabetics had more cancer than the general population questioned during the survey, and the ratio of the observed to expected cases was 1.26 for males and 1.43 for females. The excess among males could have arisen by chance, but for the females and for both sexes combined the excess was statistically significant. The possibility that this excess was due to cancer of the pancreas was examined. Analysis of the mortality and morbidity data showed that this hypothesis was not a complete explanation. An apparent excess of cancer of the pancreas among diabetics might, of course, be explained by the greater likelihood of diabetes being reported when this organ is affected than when cancer occurs elsewhere. The evidence brought forward by Jacobson supports the hypothesis that the incidence of cancer is higher among diabetics than among non-diabetics, but information obtained by canvass of households is subject to possible bias and may perhaps be diagnostically inaccurate. Despite these difficulties, this method avoids some of the objections that can be raised against data collected from death certificates or hospital records.

AUTOTRANSPLANTATION OF JOINT CAPSULE

In the aetiology of the rheumatic diseases allergic reactions have been regarded by many investigators as of great importance. Desensitization has therefore been the aim of several methods of treatment, but the results have not been always successful. In 1931 Forbes Mackenzie[1] published the case of an elderly woman with arthritis who fractured the neck of her femur. From the time of admission to hospital her arthritis steadily improved, she became much more active, the fracture united well, she lost her rheumatic pain and anaemia, and in her own words became a "new woman." Impressed with this result, Forbes Mackenzie decided to operate in certain cases of severe arthritis, including cases of Still's disease, by trephining the shafts of long bones, and obtained encouraging results. He found rarefaction and decalcification of the bone, and that the marrow had undergone a degenerative change, running out of the bone as a thin oily fluid, cultures of which were negative. These results were reported in the *Australian Medical Journal* in 1931 and in the *British Medical Journal*[2] in 1936, but afterwards seem to have been neglected. It is probable that the improvement obtained with this method of treatment rarely lasted long, as was the experience with treatment by injection of the patient's own blood.

Temporary improvement has often been noticed in rheumatic patients after operation on bones or joints and has been attributed to the entry into the circulation of antibodies from the damaged tissues. Novotny,[4] a Norwegian surgeon, was impressed with this effect, which often lasted for months, though most patients eventually relapsed. As injection of the patient's own blood was so commonly ineffective, he concluded that the improvement after operation might be due to the liberation of sessile antibodies from the damaged rheumatic tissues. Bray[5] had already suggested that the mobilization and introduction of sessile antibodies into the circulation might have a desensitizing action. Novotny therefore sought for a means of prolonging this effect, and about ten years ago he decided that it might be achieved by the excision of a piece of capsule from an affected joint and its subsequent transplantation. He has now reported the results in twelve cases of an operation in which he removed pieces of the capsule of the knee-joint and transplanted them in the abdominal wall in close contact with the deepest layers of the skin to take advantage of the active desensitizing power of the skin. In some cases he sought to prolong the effect

[1] *Med. J. Aust.*, 1931, 1, 441.
[2] Ibid., 1932, 2, 690.
[3] *British Medical Journal*, 1936, 1, 306.

[5] *Recent Advances in Allergy*, 1937, London.

by the subcutaneous injection of an extract prepared from a section of the capsule, but he has not yet made a large enough number of observations to report on this.

Results of the operation have been encouraging so far. Novotny describes some of his cases in detail and discusses the underlying pathology: the series included one of gout and one with a history of gonorrhoea many years previously, though it was probably a rheumatoid rather than a gonorrhoeal arthritis. He recognizes that unless the source of the allergen is sought for and removed, or unless it has died out over the course of years, the effect of treatment may not be of long duration. While the number of cases investigated is insufficient to justify any final conclusions, this method of treatment deserves further study.

NEW HOUSES

The well-being of the population, as reflected in the vital statistics, continues to improve in spite of the fact that many still live in conditions in which even to achieve cleanliness is a triumph. A few years ago it was estimated that about one-third of the houses in this country had no bathroom, and recent building will not have greatly increased the proportion. It is of course still a commonplace for three members of a family to share a small bedroom. Whatever may be thought of the speed with which new houses have been built since the war, or of the restrictions which limit the building of privately owned houses, the care which is now being taken by local authorities in the planning and construction of houses is a great improvement on the haphazard methods of the nineteen-twenties. To see what advances have been made it is only necessary to look at the excellent photographs in the Ministry of Health's new *Housing Manual*,[1] which is a credit both to the Ministry and to the Stationery Office. In the 1944 *Manual* the emphasis was primarily on the provision of three-bedroom two-storey houses. In the new *Manual* local authorities are advised to branch out and provide homes for the elderly, for the single man or woman, for the larger family, and even for the "high-income groups," and shown how to blend site planning and house design. The larger floor area permitted since 1945 (900–950 sq. ft. compared with 800–900 sq. ft.) has given architects a chance to design houses which, though they could hardly be called spacious, do allow a family some scope to expand, especially if space heating is used to make all the rooms habitable in cold weather.

Mackintosh[2] defines the essential purpose of housing "as the provision, so far as structure and equipment can do so within limits of cost in capital and maintenance, of the conditions of comfort, health, and enjoyment needful for making a home and for the nurture of a family." He adds that this calls for a new and progressive outlook in those responsible for providing the homes of the future and the abolition of traditional and conventional ideas and methods. It now seems to be accepted that every family, and many individuals, are entitled to a separate dwelling, whether it be a house or a flat, but before this can be achieved several million more houses will have to be built, and at the same time a great many will, we hope, be pulled down. It is therefore of the greatest importance that the form of houses and towns should not, in Mackintosh's words, prove a weakness in the structure of society, and on this the Ministry's *Manual* has much useful advice to offer. In this connexion it appears from the suggested lay-outs that the interests of the community in a residential area are grouped around the following: day nursery, school, shops, church, community centre, allotments, and public house. In *Charter for Health*[3] the British Medical Association made known its views about the importance of housing in relation to health, putting good housing first among the environmental factors which determine a people's health. Only by the application of new ideas and methods will it be possible to counteract the sense of frustration voiced by Clough Williams-Ellis,[4] who asked a few years ago: "Why have to waste energy of body and of spirit in fighting all our lives against inconvenience, ugliness, dirt, overcrowding, noise, traffic delays, lack of sunlight, lack of open-air amenities, lack indeed of all or most of the basic things needed even for a merely tolerable existence, when by reasonable forethought and planning we could secure them all?"

NEW MINISTRY APPOINTMENTS

Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health and of the Ministry of Education, will retire on May 11 next year on reaching the age limit. Dr. J. A. Charles has been appointed to succeed him, and Dr. G. E. Godber succeeds Dr. Charles as Deputy Chief Medical Officer. When Sir Wilson Jameson followed Sir Arthur MacNalty as Chief Medical Officer in November, 1940, he entered a period of office that was to be more arduous than any his predecessors had experienced. His energy and ability were conspicuous during the war years, when great responsibility lay on those who administered the nation's medical services, sometimes with barely adequate resources. Since the war the controversy about the National Health Service Act has put him in the difficult position of serving a Government often in conflict with the representatives of his own profession, but he has continued to serve both the Ministry and the profession's needs with distinction. Wilson Jameson, as he then was, became Dean of the London School of Hygiene and Tropical Medicine in 1931, and he was also Professor of Public Health in the University of London. In 1942 the Royal Society awarded him the Buchanan Medal for distinguished administrative service to the science and practice of hygiene. He received his knighthood in 1939, being created K.C.B. four years later; he was appointed G.B.E. this year.

Dr. Charles brings to the office a wide knowledge of medical administration gained as Medical Officer of Health of Newcastle-upon-Tyne and in his present post of Deputy Chief Medical Officer at the Ministry, which he entered in 1944. During the past few years he has paid official visits to all the Scandinavian countries—where he made a special study of the hospital and public health services—and to the U.S.A. Dr. Godber was appointed a medical officer of the Ministry of Health in 1939 and first served in the Nottingham Region. In 1946 he was appointed a senior medical officer and in 1948 became a principal medical officer. Before joining the Ministry he was Assistant County Medical Officer of Health for Surrey.

ORIGINS OF THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

BY

STANLEY ALSTEAD, M.D., F.R.C.P., F.R.F.P.S.

Regius Professor of Materia Medica and Therapeutics, Glasgow University

The Royal Faculty of Physicians and Surgeons of Glasgow owed its birth to a growing appreciation of communal responsibility in matters relating to health and disease. It often happens that popular opinion, amorphous and inarticulate, suddenly crystallizes out in the enterprise and energy of one man. Such a man was Peter Lowe, the Founder of the Faculty. No reliable information exists regarding his origin and early education, but we know that he spent 30 years of his professional life on the Continent—mainly in France, where he was successively surgeon to Henry III and Henry IV, Kings of France.

As Duncan aptly remarks on the period 1566–96: "During all these 30 years France was a prey to fierce internecine religious wars . . . There could certainly be no period better fitted for a military surgeon to practise all points and operations of surgery." There is indirect evidence that Lowe was an educated man and apparently a Master of Arts, though his university was never mentioned. Characteristically ahead of his time, Lowe published his professional writings in English rather than the learned tongue. When the occasion demanded it, however, he resorted to Latin with equal facility; and his publications were liberally seasoned with references to classical authors.

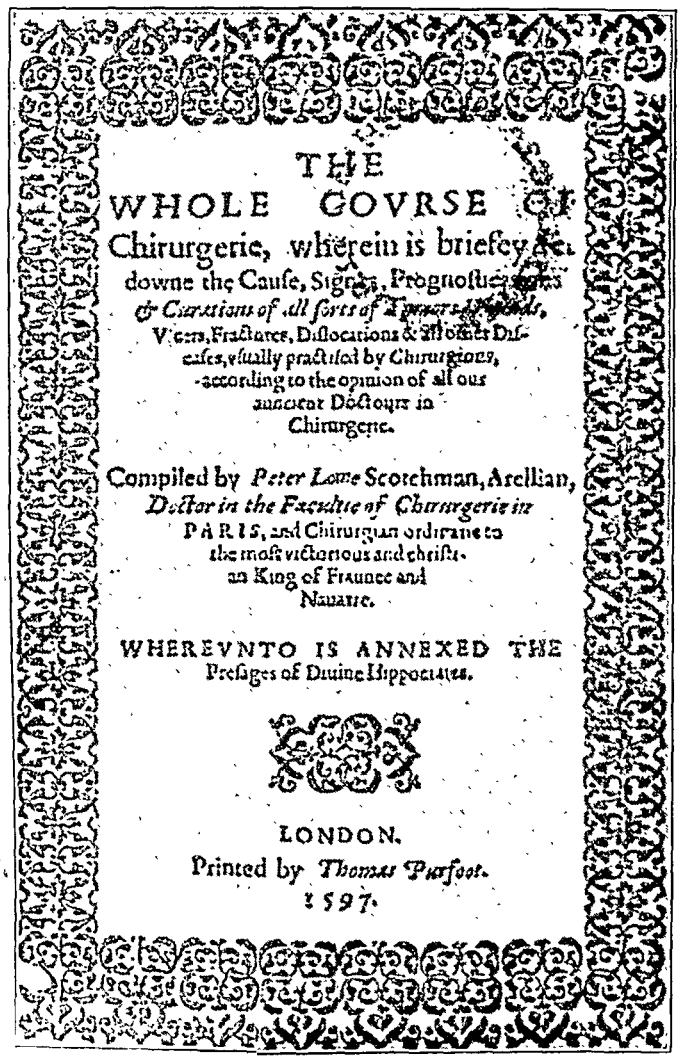
MAISTER PETER LOWE

Founder of the Royal Faculty of Physicians and Surgeons of Glasgow

Peter Lowe's Campaign

Immediately after his translation from Seine to Clyde, Lowe began his campaign for the organization of medical practice in the West of Scotland; and there is abundant evidence that he used the Paris institutions as his model. In 1598 there occurred in the Kirk Session a sudden ebullition of interest in the credentials of medical practitioners, and this resulted in the inauguration of an examining board. That the exertions of Master Peter Lowe were primarily responsible for these stirrings on the waters cannot be doubted. Not content with this, however, he memorialized King James VI on the subject, and in the second edition of his work, *A Discourse on the whole Art of Chyrurgerie*, he recalls this in the following words:

"It pleased his Sacred Majestie to hear my complaint about some fourteen years ago upon certain abusers of our Art, of divers sorts and ranks of people, whereof we have good store, and all things failing, unthrifts and idle people do commonly meddle themselves with our Art, who ordinarily do pass without either trial or punishment. The matter being considered, and the abuse weighed by his Majestie and Honourable Council, thought not to be tolerated, for the which I got a privilege under his highness privy seal, to try and examine all men upon the Art of Chirurgerie, to discharge, and allow in the West parts of Scotland, who were worthy or unworthy, to profess the same."



The Faculty's Charter

The Charter bears the date the penult day of November, 1599. After a brief reference to the lamentable state of medical affairs in the West of Scotland, it proceeds to confer on "Maister Peter Low, our Chirurgiane and Chief Chirurgiane to our dearest son the Prince [Prince Henry, heir apparent, who died in 1612 at the age of 19], with the assistance of Mr. Robert Hamiltone, professoure of medicine, and their successors, indwellers of Citie of Glasgow . . . full power to call before them . . . all persons professing or using the said Art of Chirurgerie."

"The Visitors"—the official designation of Peter Lowe and Robert Hamilton—were to "visit every hurt, murdered, poisoned, or other person taken away extraordinarily" and to report to the Magistrates. As regards the practice of medicine (as distinct from surgery), their powers were limited to inhibiting therefrom all but persons possessed of "a testimonial of a famous university where medicine be taught. . . ." Only drugs which had been approved by the Visitors, assisted by one William Spang, an old pharmacist of the burgh, could be offered for sale, and poisons which included "arsenick" and "sublemate" were to be sold, under pain of a fine of 100 marks, only by apothecaries, who were also charged to take caution

of the purchasers. Other duties of the Visitors are thus summarized by Duncan: to give monthly advice gratuitously to the diseased poor, to make provision for continuity of succession in the office of Visitor, to make by-laws, and to ensure the exemption of the members from taxation and personal service of specified kinds.

The comprehensive nature of the charter as an instrument of practical policy touching medical and pharmaceutical practice provides additional light on the character of the surgeon who inspired it, for it is evident that Peter Lowe returned to Scotland as a man with a mission. The distinction made between members practising as physicians and those practising as

surgeons was in accordance with the custom of the times. Surgery was a handicraft to be learned in the same way as any other manual art. Medicine was recognized as a subject of academic study; but in 1599 none of the Scottish universities had given a proper place to the teaching of medicine (Duncan), and accordingly the physicians were obliged to take their degrees at Continental universities.

Notwithstanding this difference of professional status and training, it was clearly Peter Lowe's firm intention to bind into a single fellowship those who represented the two great branches of the healing art. At the same time he carefully excluded the barbers from any mention in the charter, selecting for his surgical colleagues in the Faculty only those who did not "barbourize." In his *Chirurgerie* Lowe is unsparing in his contempt for the barbers: "Usurping the name of Chirurgion . . . they have scarce the skill to cut a bearde, which properly pertaineth to them." Nevertheless, and almost inevitably, the barbers were admitted to the Faculty within a year or two—but as dependants and not as crafts-brethren, being described in the Minutes of June 22, 1602, as "a pendecle of chirurgerie."

Problems and Anxieties

anxieties which the incorporation had to resolve in the three and a half centuries to follow the granting of the charter. These vicissitudes included the formulating of proper conditions for apprentices, the inauguration of systematic teaching, the contest between the surgeons and the barbers, and protracted differences of opinion between the Faculty and the Town Council and the University respectively. Details of some of these phases are available in Duncan's classical work, *Memorials of the Faculty of Physicians and Surgeons of Glasgow, 1599–1850.* The memorials also reveal the constant concern of the Faculty to foster the objects of its charter, protecting the public from the depredations of the charlatan while maintaining the honour and dignity of the profession of medicine.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

MANAGEMENT OF ACUTE PNEUMONIAS IN ADULTS

BY

J. G. SCADDING, M.D., F.R.C.P.

Dean, Institute of Diseases of the Chest; Assistant Physician, Brompton Hospital; Physician and Senior Lecturer in Medicine, Postgraduate Medical School of London

Since the introduction of chemotherapy most patients with pneumonia have been treated in their own homes. This means that therapy is often begun without the establishment of a specific diagnosis by laboratory methods; and, indeed, from the practical standpoint such a procedure is unnecessary in most cases, even though in a minority it is an essential guide in therapeutics. In the practical management of pneumonias, therefore, it is desirable to adopt a procedure which, while not leading to unnecessary calls on laboratory facilities for the general run of patients, makes available the maximal degree of help from the laboratory for the minority in which such aid is required. For working classification acute pneumonias may be divided into three main groups

Acute Bacterial Pneumonias

Of these, pneumococcal pneumonia is the most frequent, constituting 70 to 80% of the group. Haemolytic streptococcal, staphylococcal, and Friedländer's bacillus pneumonias are the most important other members. The pneumococcus and haemolytic streptococcus are, in general, sensitive to sulphonamides, and most strains of staphylococcus show some sensitivity. All three are sensitive to penicillin, though resistant strains, especially of the staphylococcus are encountered. Friedländer's bacillus is not responsive to either of these agents, but is fully sensitive to streptomycin; fortunately, acute pneumonias due to Friedländer's bacillus are rare in this country.

Virus Pneumonias

This is a group to which much attention is being directed at present. It may be subdivided as follows:

1. *Pneumonias Associated with Epidemic Influenza.*—There is good evidence that these are due to the combined effects of the influenza virus and a variety of independently pathogenic bacteria, the relative contribution of the virus and the bacteria to the pathological picture varying from case to case. These pneumonias are essentially of mixed origin, and it is certainly misleading to regard them as characteristic of virus pneumonias. It is probable that the bacterial component of the infection is susceptible to treatment by appropriate specific agents, but there is as yet no satisfactory evidence about the specific treatment of the group as a whole.

2. *Psittacosis–Ornithosis Group.*—Viruses of this group may give rise to illness in, or be carried by, birds of the parrot family, pigeons, certain other birds, and possibly by some small mammals. There is some evidence that the human infection is susceptible to very large doses of penicillin, but the newer antibiotic aureomycin appears to be fully effective.

3. *Pneumonias Due to Other Viruses.*—There are certainly other viruses which can cause pure virus pneumonias in man. The identification of these viruses has hitherto proved very difficult, and is a research project rather than a practical clinical procedure. Pneumonias due to viruses of this group generally show no response to sulphonamides, penicillin, or streptomycin; they may respond to aureomycin and possibly to chloromycetin.

Aspiration Pneumonias

Under this heading are included all those pneumonias which are occasioned rather by a breakdown of the normal mechanical defences of the lower respiratory tract than by the presence of specific invasive organisms. The most obvious examples are the hypostatic and terminal pneumonias, in which the prognosis is that of the underlying condition. Many other pneumonias belong to this group, notably some of those which occur in persons who have excessive secretions in the respiratory tract for one reason or another—e.g., the chronic bronchitics, sufferers from chronic nasal catarrh, and patients with acute respiratory catarrhs of various sorts. These pneumonias may be diffuse or localized. The former will present as basal bronchopneumonias in bronchitic subjects; the latter often do not present clinically as acute pneumonias at all, and will therefore not be further discussed here. In this group as a whole the organisms most frequently found in the sputum are *Str. viridans*, non-haemolytic streptococci, pharyngeal neisseriae, Pfeiffer's bacillus, and possibly some of the less invasive types of pneumococcus—in fact, a flora similar to that of the upper respiratory tract

Treatment

With these considerations in mind we may consider the management of a patient who presents with acute pneumonia. In such a case the invading agent will not be known at the beginning of treatment. Hence the most reasonable procedure is to obtain material for the later establishment of an aetiological diagnosis if required; to treat immediately on standard lines; and to modify treatment later, if necessary, in the light of any information which may become available about the aetiology. This standard treatment may be considered under two headings: general and symptomatic measures, and specific treatment.

General Measures Applicable to all Pneumonias

The patient with acute pneumonia must be kept in bed with adequate nursing care. He should occupy a well-ventilated room maintained as far as possible at an equable temperature of about 65° F. (18.3° C.). Patients are often more comfortable if kept slightly propped up with pillows, but some prefer lying flat, and the patient's comfort should decide the position in which he is nursed. In gravely ill patients slight changes of position should be made every few hours in order to avoid hypostatic effects. Physical examination should be done carefully, but not more frequently than once daily. If there is difficulty in diagnosis, either of the primary disease or its complications, bedside radiography imposes little strain on the patient and should be employed. It should be remembered that all drugs

used in symptomatic treatment can have undesirable effects, and no such drug should be prescribed unless there is a real indication for it.

Diet

In the acute stages of pneumonia the patient usually has complete loss of appetite, and as the duration of the disease is short there is little point in attempting to force unwanted food upon him, provided an adequate intake of fluid and carbohydrate is maintained. For an adult, a total fluid intake of about 4 pints (2,500 ml.) daily is suitable. Part of this may be given in the form of drinks sweetened with as much glucose or cane sugar as his taste will permit, flavoured with any suitable fruit juice, and made up in plain or soda water. Milk may be given, hot or cold, preferably with extra sugar and flavoured in any acceptable way. If the patient does not like sweet drinks lactose may be used instead of glucose or cane sugar; lactose may also be useful in cases with abdominal distension, as it gives rise to less intestinal fermentation. Eggs, cereals, custards, thin buttered bread or toast, fish, minced lean meat or chicken, mashed potato, and vegetable *purées* can be added when the patient's condition permits.

Relief of Pain

Pleuritic pain may be relieved by a kaolin poultice. Care should be taken that this is applied in such a way as to avoid interference with respiratory movement. If pain is severe, morphine or other opium derivatives, or pethidine may be required (see below). Occasionally the pleuritic pain may be extreme, and if in such a case it is well localized the injection of 5 to 10 ml. of 2% procaine just external to the parietal pleura in the painful area may be helpful.

Sleeplessness

The combination of restlessness, pleuritic pain, and irritating unproductive cough often demands the use of morphine or one of its analogues to secure sleep. The only danger of these drugs arises from their depressing action on the respiratory centre and the intestinal motility. They should not be given to patients with cyanosis due to a complicating bronchitis, or to those with any signs of abdominal distension. In all other patients morphine, 1/6 to ¼ gr. (10 to 15 mg.), or pethidine, 50 to 100 mg. hypodermically, can be used if necessary to secure sleep. If ineffective cough is the chief obstacle to sleep, codeine phosphate, ½ to 1 gr. (30 to 60 mg.), may be sufficient. Should it be necessary for the relief of pain and to secure sleep to administer morphine to a cyanosed patient, oxygen must be given by an efficient method. If there is so much complicating bronchitis or severe abdominal distension that morphine and its analogues are contraindicated, paraldehyde is generally the most useful hypnotic. It may be given by mouth in a dose of 2 drachms (7.5 ml.) in a suitably flavoured mixture, or in ½ oz. (30 ml.) of whisky or brandy; or by rectum, 4 drachms (15 ml.) in 6 oz. (180 ml.) of water.

Delirium

This complication may require treatment. Reduction of temperature by tepid sponging and the relief of anoxia by oxygen administration may be effective. Phenobarbitone soluble, 1 to 2 gr. (60 to 120 ml.) subcutaneously, or paraldehyde by rectum as suggested above may be helpful. In patients known to be alcohol addicts, whisky or brandy, ½ oz. (30 ml.) four-hourly, should be given if there is delirium. Apart from this, alcohol is of no value in the treatment of pneumonia.

Cough

Distressing and ineffective cough should be controlled with a suitable linctus containing codeine or, in more troublesome cases, diamorphine (heroin). A productive cough is to be encouraged by supporting the patient during bouts of coughing, by simple postural methods if the general condition permits, and by the relief of pleural pain.

Meteorism

Abdominal distension may become troublesome. In such cases treatment should be started with a simple soap enema and the passage of a flatus tube. If these measures are not sufficient, turpentine or bile enemas and the subcutaneous injection of pituitary extract, 0.5 ml., or of prostigmin, 1 mg., may be effective. The administration of oxygen in a concentration as near 100% as possible from a B.L.B. or similar mask may lead to diminution of the distension by causing absorption of the gases into the blood stream.

Oxygen Administration

The anoxaemia of pneumonia is probably responsible for many of the so-called toxic symptoms. It is due to many factors, some of which can be relieved by oxygen administration. In any cyanosed patient, therefore, oxygen should be administered by an effective method. This applies particularly to those forms of pneumonia which are complicated by much bronchitis. An efficient mask of the B.L.B. type or a tent should be used.

Cardiovascular System

Pneumonias mainly affect the heart indirectly, through the peripheral vascular system and by anoxia, though there may be some direct toxic effect on the myocardium. There is no justification for the routine use of drugs alleged to have an effect on the heart. In particular, digitalis should be given only if there is pre-existing cardiac disease for which its use is indicated or if an abnormal rhythm develops. The form of circulatory collapse most commonly seen in patients gravely ill with pneumonia presents a picture of falling blood pressure with rising regular pulse rate. Digitalis and similar drugs have no effect in cases of this sort. Analeptics such as camphor, nikethamide, and "cardiazol" are widely used to combat this condition but since the essential cause is a peripheral vasomotor failure, and any stimulating effect that may be produced by these agents is of central origin, their value is doubtful. Adequate oxygen therapy and the administration of glucose are the most rational procedures.

Specific Treatment

In the case of apparently primary pneumonias of lobar extent the pneumococcus is so frequently the causative organism that, pending an aetiological diagnosis, it is reasonable to treat all cases of this sort in the first instance as if they were caused by the pneumococcus; but whenever possible material should be obtained for bacteriological examination before beginning treatment. Sputum is the best material, if a good specimen is available, and this can generally be produced by encouraging the patient to cough. If sputum is unobtainable a throat swab may give useful information, but is less reliable. Lung puncture is justifiable only for special purposes. In any gravely ill patient a blood culture should also be taken before treatment is begun.

Sulphonamides

In a case of average severity, after a specimen of sputum has been obtained for culture sulphonamide treatment should be instituted. Of the commonly available sulphonamides, sulphamezathine causes relatively little nausea and vomiting and, having an acetyl derivative of high solubility, very rarely gives rise to renal complications. It is therefore

suitable for routine treatment. Adequate dosage is essential: for an adult an initial dose of 3 g. should be given, followed by 1 g. four-hourly, or in severe cases 1.5 g. four-hourly. This dosage should be continued for two or three days; if there has been a favourable response it may then be reduced to 0.5 g. four-hourly. In the average case treatment should be continued for five or six days, giving a total dose of 25 g. to 30 g. Adequate fluid intake should be ensured while sulphonamides are being given.

If there is a poor response to treatment, with no improvement in the patient's condition after 48 hours, the cause should first be sought. If material for bacteriological examination has been obtained at the beginning of treatment, the reports should then be available and may provide a clue to the failure to respond. It may be that the organism is poorly sensitive or not sensitive at all to the sulphonamide in use—e.g., infection with *Staph. aureus* or Friedlander's bacillus. The possibility of acute tuberculous pneumonia, or of the pneumonia being secondary to some underlying lesion of the lung, such as a carcinoma obstructing a bronchus, should also be considered. If all these possibilities can be excluded, local complications, especially the early development of empyema, should be suspected; if there is any suspicion of empyema the chest should be needled over the area most dull to percussion. If none of these factors is present and the organism is sensitive both to sulphonamides and to penicillin, or relatively insensitive to sulphonamides and sensitive to penicillin (such as *Staph. aureus*) penicillin treatment should be instituted.

Penicillin

Penicillin is not only indicated in cases which have failed to respond to sulphonamides or which are caused by organisms resistant to these drugs, but in certain instances is required from the beginning of treatment. Penicillin is indicated in cases of staphylococcal infection and those in which sulphonamides are contraindicated—for instance, in patients known to be sensitive to sulphonamides or in whom there is antecedent renal disease. In addition, in patients who are severely ill at the time when treatment is begun, who are severely dehydrated, or who have troublesome vomiting, penicillin from the beginning is a preferred form of treatment to sulphonamides in spite of the greater difficulty of its administration. In some severe cases it may be advantageous to give sulphonamide and penicillin treatment simultaneously. The most reliable way of giving penicillin remains the three-hourly intramuscular injection: 15,000 to 25,000 units three-hourly will maintain an effective blood concentration in most cases of pneumonia due to penicillin-sensitive organisms. The inconvenience of such frequently repeated doses may be avoided by giving larger amounts of soluble penicillin less frequently—e.g., 100,000 to 200,000 units six-hourly—but the maintenance of a constantly effective blood concentration is not entirely certain by this method. The most convenient way of administration of penicillin is by using one of the slowly absorbed preparations, such as procaine penicillin in oil. Of this, 100,000 to 200,000 units every 12 hours will usually, but not certainly, maintain an adequate concentration.

Treatment of Virus Pneumonias

The diagnosis of virus pneumonia is unlikely to be made in practice except as a result of exclusion of other diagnoses or in the presence of an epidemic.

Pneumonias Associated with Epidemic Influenza.—These should be treated on the lines applicable to the bacterial component of the infection. There is no indication at present of any agent effective against an influenza virus itself.

Pneumonias of the Psittacosis–Ornithosis Group.—These cannot be diagnosed with certainty clinically, but may be suspected when the illness starts with severe constitutional symptoms, when there is the later development of signs of consolidation, and if there is a history of contact with parrots or pigeons. Proof of the diagnosis will generally rest upon a positive complement-fixation test in blood taken during convalescence. If the diagnosis is suspected, very large doses of penicillin (up to 2,000,000 units a day) may be effective. Aureomycin appears to be curative in oral doses of 0.5 g. six-hourly, and should be used if available. Chloromycetin may also be effective.

Pneumonias presumably due to unidentified pneumonotropic viruses ("primary atypical pneumonia") may be suspected clinically when the illness starts with constitutional symptoms, the signs of pneumonia appear late (about the third to fifth day), the leucocyte count remains low, and there is no response to sulphonamides or penicillin. The suspicion would be supported by the occurrence of similar cases in the neighbourhood and by the development of a high titre of "cold agglutinins" in the blood during convalescence. In such cases aureomycin has been reported to be of value. It would be reasonable to give it by mouth in doses of 0.5 g. six-hourly to a severely ill patient, but the great majority recover after a relatively brief illness, and the drug is at present scarce and expensive.

Treatment of Aspiration Pneumonias

The mildest pneumonias of this group are unlikely to be recognized clinically without the aid of radiography: the most severe occur as complications of other serious illnesses. The types which are most likely to present clinically as "pneumonias" are the patchy basal bronchopneumonias of the bronchitic subject and some of the post-operative bronchopneumonias. In these, as in all pneumonias of this group, there is a considerable mechanical factor, early attention to which may cause rapid alleviation of the condition before there has been any severe invasion by bacteria, although infection by specifically invasive organisms may occur at any stage. It is therefore wise in such cases to start as with apparently primary pneumonias by obtaining material for bacteriological examination and instituting standard sulphonamide or penicillin therapy. At the same time the mechanical factors should receive careful attention. The patient must not be allowed to remain constantly in the unfavourable posture which he will naturally tend to adopt. He will most often be found lying in the position which prevents him from coughing—i.e., that in which the affected area of lung is least favourably placed for the expulsion of secretions. He should be made to change his position into a more favourable one and encouraged to cough. Deep breathing is helpful; administration of 7% carbon dioxide in oxygen may have a comparable effect in uncooperative patients. In post-operative cases no tight bandages which might obstruct full respiratory movement should be permitted. Abdominal distension, if present, should receive attention. Only in special circumstances will more drastic measures be required, such as bronchoscopy or bronchial suction. If these steps to deal with the mechanical factor result in rapid relief of symptoms and disappearance of physical and radiological signs it is usually safe to discontinue sulphonamide or penicillin treatment. If, however, this happy result does not ensue, it may be assumed that infection by an invasive organism has occurred, and investigation and treatment as suggested for apparently primary pneumonia are indicated.

Convalescence

Convalescence after pneumonia proceeds at a very variable pace. In a case of pneumococcal pneumonia of average severity the patient may be allowed out of bed after the temperature has been normal for seven days. In cases of greater or less severity appropriate periods of bed rest are needed. In pneumonias of the aspiration type the patient should be allowed out of bed as soon as his general condition permits. Breathing exercises, which should be applied as therapy in aspiration pneumonias, are helpful in convalescence from acute specific pneumonias by hastening the return to normal lung function, and should be started soon after the temperature falls. After resolution appears to be complete clinically it should be confirmed radiographically. An adequate period of convalescence should be enforced, the duration of which will depend upon the sort of life to which the patient has to return.

A SNOOP AT N.H.S.

Mass Observation, which since 1937 has been uncovering the opinions of the British people on such contrasting topics as juvenile delinquency, clothes rationing, and public houses, has now investigated their attitude towards doctors. In a report published this week[1] the observers conclude that the National Health Service is, so far, a welcome innovation, and record general appreciation and some surprise that the attitude of the family doctor underwent no noticeable change on the appointed day. "I called in the doctor to my baby son on the day of the inception of the new Service," said a young father who was interviewed. "I don't know what I expected, but I did feel mildly surprised when the doctor arrived at the house and behaved precisely as he had always done."

This survey not only records universal resentment against the size of the weekly contributions, but the inquisitors fall into the error of their witnesses in believing the entire sum of the National Insurance contribution to be paid into the Health Service. The reply from one housewife is typical: ". . . We never paid a doctor 5s. a week, but received the same attention from the hospital under the H.S.A. scheme for 4d. a week."

The report attempts to throw light on the ways in which patients occupy themselves in the waiting-room. All are resigned to a long wait, but appreciate that the doctor's slowness with each patient indicates a painstaking consultation for themselves. They complain they cannot afford to spend so long away from their own homes, and all condemn the person taking advantage of "free" treatment to worry the practitioner with a trivial complaint or a request for an unnecessary bottle of medicine. The conversation among the waiting patients is predominantly concerned with each other's pathology. An incidental disclosure of the report is the number of patent medicines still kept in British households despite the removal of the financial barrier to medical consultation. Three families in five maintain a medicine cupboard, the most popular contents of which are aspirins, laxatives, vitamin preparations, antiseptics, "tonics," and cough cures. The advantage offered by patent medicines is one of time—it is easier and quicker to swallow a dose in the house than to go out and visit the doctor.

The opinions of only two doctors are included in the survey, though a larger number of practitioners were interviewed by the authors. These two are anonymous partners with conflicting opinions about the N.H.S., but both are agreed on the increase in their medical and paper work since its inception, and on the inadequacy of the capitation fee.

The report is far from comprehensive and leaves the serious reader with considerable doubt whether it mirrors the true opinions of the public at all. It makes entertaining reading, however, and Mr. Ronald Searle's illustrations are scrupulously fair in their ungenerosity to the profession and the patients.

Correspondence

Alcohol and Cirrhosis of the Liver

SIR,—Your leading article entitled "Alcohol and Cirrhosis of the Liver" (November 5, p. 1030) raises several interesting points. There is evidence that in occupations which involve an excessive intake of alcohol there is a high mortality from cirrhosis of the liver. Thus the standard mortality ratio from cirrhosis of the liver in inn- and hotel-keepers is 1158—i.e., 11½ times the mortality from cirrhosis in the population as a whole. In barmen the standard mortality ratio is 600, or six times the rate in the population as a whole.

In inn- and hotel-keepers there is also a high mortality from diabetes, with a standard mortality ratio of 325, or three and a quarter times the rate in the population as a whole. The relationship between alcoholism and diabetes is an interesting one, and the association is partly explained by the fact that in many alcoholics the calorie intake is in excess of energy requirements. This will lead to obesity and hence a predisposition to diabetes. In diabetes, as in chronic alcoholism, there is often a fatty infiltration of the liver, as well as nutritional deficiencies caused, possibly, by deficient intake, defective absorption, or ineffective utilization of vitamins and amino-acids.

It has been pointed out that the addition of choline to alcoholic or saccharine beverages may be of benefit, but there arises the additional possibility that an excessive intake of sweets in children may lead to liver damage, as it would appear from the work of Professor C. H. Best and his colleagues (November 5, p. 1001) that alcohol and sugar are equally effective in producing cirrhosis of the liver, at any rate in experimental animals. There is a danger, therefore, that a child who is eating large quantities of sweets will have a diet which is unbalanced and defective in protective foodstuffs; this may lead not only to dental defects but possibly also to liver damage, a damage which may not show any immediate clinical effect but may possibly lead to a reduced resistance to hepatotoxic agents.

There is some evidence that an excessive intake of sweets during pregnancy may lead to an excess mortality in the infant. Thus the mortality is high among infants of mothers whose husbands are employed in certain occupations associated with sugar confectionery, as may be seen from the following table.

Code No.		Deaths of Legitimate Infants, 1930–2	Legitimate Births, 1931	Annual Rate per 1,000
375	Sugar confectionery makers, moulders, and coverers ..	24	101	79
671	Retailers of sugar confectionery (sweets)	79	252	105
701	Salesmen of sugar confectionery (sweets)	22	52	141
	Total ..	125	405	103

The combined rate of 103 per 1,000 legitimate live births, with a standard error about nine, must be regarded as significantly high in comparison with the national rate of 61.6 at that time. The adverse effects during pregnancy of an increased intake of sugar or alcohol may be due to liver damage and an increased liability to toxaemia. We know, for example, that there was a decreased mortality from toxaemia during the war years. It is interesting to note that during the period 1939–49, when sweets and sugar were rationed, there was a marked decrease in maternal and infant mortality, in dental defects in children, and in mortality from diabetes and cirrhosis. There are, of course, many factors involved in these decreases, but no doubt the diminished intake of alcohol and sugar was responsible for some of these effects.

If the suggestion of adding choline to alcoholic drinks is to be taken seriously, why not include sweets at the same time? At any rate mothers should be warned of the undesirability of giving large quantities of sweets to their children, a warning

which has often been given in the past, but to which additional support is given by this new evidence. It is possible that the rationing of sweets and sugar confectionery is a blessing in disguise.

All the standard mortality ratios quoted in this letter are statistically significant and refer to the experience in the years 1930, 1931, and 1932.[1]

—I am, etc.,

W. HOBSON.

Sheffield.

Uses of Streptomycin

SIR,—In your leading article (November 12, p. 1098) you state that the decision to use streptomycin is emphatically one for the expert only. This pronouncement would appear to preclude the general practitioner from using this valuable antibiotic, since he cannot claim to be an expert. General practitioners are however, by and large, sensible and responsible people who have received a careful scientific training and have satisfied their examiners that they are capable of carrying out treatment for their patients.

What is the use of spending time and trouble teaching students pharmacology and bacteriology and then preventing them from using the very substances they have been taught to use? What is the use of having scientific journals in which appear papers giving an account of the most recent discoveries? Are these papers intended to be read by experts only?

Now, Sir, every sensible practitioner will agree with the general tenor of your leading article and will concede at once that streptomycin is not a substance to be used indiscriminately, that it has serious toxic possibilities, and that the implications towards public health are not lightly to be disregarded. But surely it is not in the best interests of medicine that general practitioners should for all time be discouraged from using the potent remedies which science has placed at their disposal.

In this part of the U.K. the Northern Ireland General Health Services Board, acting on the advice of the Northern Ireland Ministry of Health, recently saw fit to prohibit the use by general practitioners of *para*-aminosalicylic acid, a relatively innocuous substance, on the grounds that it was "still in the experimental stage."

These prohibitions seem to imply that the general practitioner is a careless fellow, that he will take no trouble to find out the properties of a new substance, that he is sure to prescribe it in the wrong type of case, that he will either underdose or over-dose his patients, and finally that he is quite unfitted to be trusted with any new scientific discovery.

The point I want to make is that the general practitioner should be treated as an intelligent individual. He must be given the opportunity to use these new substances. To do otherwise would seem to be a further attempt to relegate him to the role he is fast assuming—that of a signpost to the nearest hospital.—I am, etc.,

H. J. CRONHELM.

Belfast.

SIR,—It would appear that the question of reinfection and reactivation in pulmonary tuberculosis is going to be one of even greater importance in the future than it has ever been. Development of resistance to a drug is due, I believe, to one of two causes: (1) the survival of a small number of "persisters" which continue to multiply when the vast majority of the sensitive organisms have been destroyed; (2) the exposure of the organisms to concentrations of a drug sufficient to retard growth but not to kill.

It is well known that live tubercle bacilli survive in a primary or other minimal tuberculous lesion which has long since ceased to show any evidence of activity, if it ever did, and that they can, years later, give rise to manifest disease. Will the streptomycin now released for general use, and the allied antibiotics which will in due course be available, leave in those people resistant strains of tubercle bacilli when the drugs are concurrently used for the many other infections against which they are potent?

Until someone demonstrates conclusively that they will not, I personally must agree with your leading article (November 12, p. 1098) that "streptomycin should be reserved for use only on the clearest indications and under the closest observation." In spite of the galaxy of talent apparently arrayed against your opinion in the columns of the *Sunday Express* (November 13)—some of it perhaps unwittingly—and in spite of forecasts of wonders yet to be in the same publication, it will be a very long time before we can dispense with the old-fashioned sanatorium routine, however carefully the drugs are used.—I am, etc.,

KENNETH MURRAY.

Eardisley, Hereford.

SIR,—I should like to pay tribute to the excellence of your leading article on streptomycin (November 12, p. 1098), arising from its general issue. Having pioneered the first trial in this country, I agree with all your points, and I only hope the medical reader will take to heart the sober advice given.

It was with great regret and misgiving that I read the bad press given to the article in some of the Sunday papers. Their reports were non-factual and irresponsible.—I am, etc.,

D. G. MADIGAN

Bromley, Kent.

Streptomycin in Ulcerative Colitis

SIR,—In your leading artucle on the uses of streptomycin (November 12, p. 1098) it is stated that in ulcerative colitis streptomycin is useless. This is true for the common type of so-called idiopathic ulcerative colitis, when no specific organisms can be isolated from the stools. In certain rare cases, however, Gram-negative bacilli, usually *Proteus* or *Ps. pyocyaneus*, can be grown from the stool. These organisms are probably secondary invaders, but if they can be eradicated, even temporarily, a remarkable cure of the ulcerative colitis may be achieved. Cases of ulcerative colitis harbouring these organisms often suffer from profuse rectal haemorrhages which ordinary treatment will not stop. A brief account of a case of ulcerative colitis treated with streptomycin might therefore be of interest.

A woman, aged 39, had been suffering from severe ulcerative colitis for 22 years. She had had periods of remission. Her present attack lasted six weeks before admission. She got rapidly worse and on admission was passing about 24 motions during the 24 hours. Her stools contained blood, pus, and mucus. Stool culture yielded a profuse growth of *Ps pyocyaneus* and *Proteus*. A blood examination showed bleeding time three minutes; clotting time four and a half minutes; prothrombin time 45 seconds; platelet count 300,000; haemoglobin 58%; R.B.C. count 3.0 m.; C.I. 0.9; W.B.C. count 18,000. She had a high, remittent pyrexia, and was markedly wasted and toxic-looking but mentally alert. Apart from tenderness over the colon no other evidence of organic disease was found. Sigmoidoscopy showed gross ulceration of the rectum and lower sigmoid colon typical of acute ulcerative colitis.

The patient was at first treated with a course of "sulphasuxidine" and penicillin injections, and was also given repeated blood transfusions. She had a high-calorie low-residue diet and added vitamins. On this treatment her diarrhoea did not clear up and her condition deteriorated rapidly. She continued to pass large quantities of pure blood per rectum, and the persistent blood loss required repeated blood transfusions. The patient's condition appeared hopeless. Another stool culture yielded the same two Gram-negative organisms, which in a broth culture were completely inhibited by streptomycin in amounts of 0.05 mg. per ml. of broth. I was fortunate in obtaining a small supply of streptomycin and started the patient on the following course of treatment: 2 g. of streptomycin was given dissolved in 12 ml. of saline; and 2 ml. of this solution was given intramuscularly four-hourly for two days, followed by 1 ml. four-hourly for three days. At the same time the patient was also given streptomycin by mouth: 2 g. of streptomycin was dissolved in 120 ml. of saline, and she was given 20 ml. of this solution four-hourly for two days, followed by 10 ml. four-hourly for three days. The patient thus received a total of 14 g. of streptomycin by mouth and intramuscular injections in five days.

This treatment had a remarkable effect. Within 36 hours of starting it the rectal bleeding had stopped, the patient's general toxic condition improved, and her pyrexia subsided. Her stools became less frequent, and two weeks after commencement of treatment she had only had one stool a day, and this was almost formed. Stool culture four days after commencement of treatment showed the

absence of the Gram-negative organisms, but they were found to be present again two weeks later, though at that time diarrhoea had ceased. She made an uninterrupted recovery. Seen four months after discharge from hospital she had gained 3 st. (19 kg.) in weight and had had no further attacks. A barium enema two months after commencement of streptomycin treatment showed appearances of the colon typical of advanced ulcerative colitis. It therefore appears that this rare type of ulcerative colitis responds dramatically to streptomycin.

—I am, etc.,

London, E.11. ERIC FRANKEL.

Medical Services of the Armed Forces

SIR,—May I hasten to reassure Dr. W. A. Bellamy (November 12, p. 1115) on the first of his two points? A field ambulance now includes one captain (non-medical) who is in fact, if not in name, an adjutant. I can support him from personal experience; the appointment is an extremely valuable one. But it does not free the commanding officer from his desk any more than does the presence of an adjutant in an infantry battalion. The amount of time spent with his men still depends, as it always did, more on the personal approach of the C.O. than on the establishment. Dr. Bellamy may rest happy on the subject of conferences. They are still fairly regularly attended. Their value is as problematical as ever.—I am, etc.,

Manchester. ROBERT G. W. OLLERENSHAW, Lt.-Col., R.A.M.C. (T).

Sudden Obesity and Psychological Trauma

SIR,—The article describing the sudden onset of obesity due to psychological trauma by Drs. H. J. Shorvon and John S. Richardson (October 29, p. 951) has prompted me to cite a case which I had in my own practice.

The patient, a woman aged 36, was married with one child. I had known her for many years. Her previous history was perfectly normal and her family history was of no significance. She was happy and well adjusted. In September, 1945, this patient underwent a dreadful experience. Her son, aged 7, was playing in the garden one afternoon. As it was becoming chilly, she called the child in and knotted a scarf round his neck. The boy returned to the garden to play and climbed a tree. He slipped while climbing, the muffler caught in a branch, and he was thus accidentally hanged. He was discovered by his mother. She immediately became hysterical, and I was called in by neighbours. Her husband at the time was serving overseas with the Army.

When I first saw the woman she was screaming and shouting and calling for her husband. I spent some time endeavouring to quieten her, and eventually gave her "nembutal," 4½ gr. (=0.6 g.). I made arrangements for her husband's immediate recall, and he arrived home within 24 hours. The patient was seen by me each day during the following week, during which time she was treated with sedation. At the end of that period she got up from bed, but refused to leave the house and spent most of her time in the garden gazing at the tree. She was depressed and became melancholic at times. For the next few months she suffered from insomnia, and took sod. phenobarb. (3 gr. = 0.2 g.) each night. Her sleep was disturbed by dreams of the accident. I may add that her husband did everything possible to help her. As he had been released from the Army, he was able to spend most of his time at home with her.

About January, 1946, I noticed that the patient was gaining weight, and she stated that she was developing a large appetite and was always hungry. In addition she had amenorrhoea, her last period being prior to the accident. On examination there was no evidence of pregnancy, and no abnormal signs could be found in any system.

I saw the patient regularly during the next six months. Her mental condition was showing some signs of improvement, but she still continued to dream about the boy each night. By August, 1947, her weight had increased to 13 stone (82 kg.) from her usual 10 stone (63 kg.). Her appetite was still voracious, and the amenorrhoea persisted. I considered that there was some relationship between the cessation of the menses and the shock, and was of the opinion that the whole clinical picture was due to some endocrine dysfunction. An estimation of her 17-ketosteroids revealed a normal figure.

Owing to the housing shortage it was impossible to remove her from her surroundings. I treated the patient with thyroid (4 gr. = 0.25 g.) daily, in conjunction with dienoestrol and progesterone. This therapy had no effect in reducing her obesity or in promoting the menstrual flow. She continued to see me periodically. She was considerably helped by the patience and sympathy of her husband, and she talked freely to me about the accident at each consultation. I considered this voluntary abreaction important and encouraged her confidences.

In October, 1947, the patient moved from her address, and away from the scene of the tragedy. Four months later menstruation restarted, and from that time her periods were regular and normal. She noticed that she tended to lose weight, her appetite became more normal, and her depression lessened. She was so much better, and her interest in life became so much more active, that in March, 1948, she obtained employment. Her progress has been maintained, and she is now restored to normal mental and physical health. Her present weight is about 10 stone, and she is most anxious to become pregnant.

There is no doubt that this patient suffered a severe psychological trauma, possibly complicated by a feeling of guilt, as she had tied the muffler which caused the accident. The immediate result was the appearance of signs and symptoms suggestive of a severe endocrine disturbance. In comparing this case with those described by Drs. Shorvon and Richardson, it will be noted that their patients all had a bad psychological history, and physical changes were only reversed after psychiatric treatment. Whereas my patient was normal, happy, and well-adjusted, and cure was effected by a simple change of scene. Her condition was probably naturally reversible.—I am, etc.,

Kingston-on-Thames. M. H. FRIDJOHN.

Congo-red Solutions for Intravenous Injection

SIR,—One of the reasons why the congo-red test for amyloid disease is little used is because the injection is often followed by severe reactions—sweating, headache, nausea, and sometimes vomiting. At least one death has been caused by its use. These reactions are due to the presence of particulate material in the injected solution. The particles cannot be brought into solution by heating, however long continued. Solutions prepared in the following way are free from particles, and can be injected rapidly (20 ml. per minute) without any subsequent reaction.

Ten millilitres of sterile water is heated in boiling water for five minutes and then transferred, using a sterile Pasteur pipette, to the ampoule containing 0.1 g. congo-red. The mixture is kept in the boiling water-bath for 1–2 minutes, then transferred to a sterile centrifuge tube, plugged, and centrifuged at 1,500 revolutions per minute for five minutes. The supernatant solution can then be cooled, removed with a syringe and long needle, and injected.

No preparation made in this way has caused a reaction, though it has been used on many patients. No doubt filtration of the solution would be equally effective, though less convenient for small volumes.—I am, etc.,

London, N.W.10. GEORGE DISCOMBE.

Use and Abuse of Vitamins

SIR,—One general practitioner must be allowed space to differ from Professor L. S. P. Davidson's views (November 5, p. 1036). Fully developed vitamin-deficiency states are not rare in this country (unless "this country" refers to Scotland). Two new cases of pellagra walked rather unsteadily into my surgery this week. I am able to select a number of cases from a series seen in the last 18 months to illustrate some unusual objective signs in frank vitamin-B-complex deficiencies to form a paper to be submitted for publication.

The altered extraction rate of flour has not solved the problem of vitamin-B deficiency. If this deficiency was of "such great importance in pre-war days" I should think it is important to-day, with the detrimental change of ratio between purchasing power and costs. Some housewives would find the following rather provocative: "If, however, after making the requisite investigations discussed above, the doctor concludes that there is a state of subclinical nutritional deficiency present, he should treat the deficiency by ensuring that the patient takes a properly balanced diet." In another place Professor Davidson emphasizes that "there is little doubt that all vitamin requirements can be adequately met at the present time from food

supplies readily available." Then follows a list of foods providing an adequate diet for a week. The list is satisfactory, but three of the items are seldom obtainable by many thousands of our people. The diet costs about 10s. per day, at a low estimate. Thousands of elderly people are living in roominghouses where the single room costs £2 per week.

If Professor Davidson and I see a similar sample of the country's population then I can only conclude that the relative rarity of vitamin-deficiency states in Edinburgh may have something to do with the higher intake of what I call porridge compared with its consumption in the deep South. Professor Davidson suggests that we should "discover and eliminate adverse social and environmental factors" and show the patient how to get an adequate diet. The factors are not difficult to discover. They make a long list added to the financial problem mentioned above, and their elimination is a complex problem occupying many worried politicians, economists, and world statesmen, as well as Lord Boyd-Orr, William Vogt, and a lot of other men and women in the street.—I am, etc.,

Hove, Sussex. JOHN F. BUCKMASTER.

Erysipeloid Treated with Penicillin

SIR,—Dr R. A. Bush reports (October 29, p. 964) a case of erysipeloid in which the identity of the infecting organism is without question. Professor R. S. Pilcher and his colleagues[1] mention briefly that eight cases of erysipeloid occurred in their series of finger and hand infections. Dr. Bush does not quote this authority; nevertheless, I believe that the University College Hospital experience is typical of many. Reports are few because "minor" conditions of the hand are still treated most frequently by house officers, and this one is unrecognized. I should like to submit to you the following observations.

1. In the last thousand septic hands seen by me a comparable clinical entity occurred eight times. One further case was suspected, but not definitely diagnosed. The severity varies considerably. The U.C.H. clinic had 8 cases in 388.

2. The very acute development Dr. Bush describes is unusual, but the virulence of infection in his case is unusual also.

3. Four of my cases only came to treatment in the second week, so that treatment of any sort was likely to be successful. In the normal course resolution occurs in two to three weeks.

4. Two early cases were treated with serum kindly provided by a veterinary surgeon. One responded promptly; the other did not, and was treated with penicillin four days later.

5. Cases seen late in the second week respond slowly to penicillin, and tend to carry over to the third when response to treatment cannot be assessed.

6. I personally use much bigger doses (1,000,000 units a day). I am not sure yet if this is necessary.

7. The commonest cause here, as in London, is minor trauma while handling fish.

8. The variability in response to penicillin and to specific serum makes one suspect that this is a picture which may be caused by a variety of related organisms. We have been unable to isolate any organism, as the cases never come to incision, and there is therefore no justification for obtaining material for examination.—I am, etc.,

Sunderland. THOMAS G. LOWDEN.

Treatment of Early Syphilis

SIR,—With reference to the paper entitled "Treatment of Early Syphilis with Penicillin Combined with Neoarsphenamine and Bismuth" by Lieutenant D. H. Miller and myself (September 24, p. 672), it has been pointed out to me that the number of cases considered by James, Mackay, and Wright[1] was not as quoted. It was stated by us that the latter had calculated the cumulative relapse rates following four different schedules of treatment for early syphilis, but, owing to a clerical error, it would appear as if only 281 cases had been considered by them, whereas in fact this figure should refer only to the sero-positive primary and secondary cases treated by one of the schedules—namely, that consisting of 2,400,000 units of penicillin alone administered over a period of 7½ days, this schedule being the one for which we cited their results. The total number of cases of early syphilis considered by these authors for the four treatment schedules was 1,034, this number being made up as follows: by 2,400,000 units of penicillin alone, 395 cases; by 4,000,000 units of penicillin alone, 126 cases; by penicillin and "mapharside," 271 cases; by penicillin, mapharside, and bismuth, 242 cases. It is very much regretted that the above facts were not brought out in our paper.—I am, etc.,

Post-operative Pulmonary Infections

SIR,—A recent typical medical coincidence with two cases prompts me to publish them together with a few conclusions and conjectures.

Case 1.—A woman of 43 had a total hysterectomy for fibroids, followed in 24 hours by an acute onset of pain in the left side of the chest accompanied by dyspnoea and slight pyrexia. There were crepitations and diminished air entry at the left base, and the condition resolved in three days with "sulphatriad" therapy. Following dilatation and curettage nine months previously she had experienced a similar attack about five days after operation.

Case 2.—A woman aged 35 had a total hysterectomy for anovular bleeding followed in 24 hours by an acute onset of pain in the left side of the chest with the same signs and course as in Case 1. In her past history a laparotomy was performed in 1941 for ectopic gestation. Evidence of chronic pelvic inflammation only was found, and it was followed by an identical chest condition.

The rarity of post-operative pulmonary complications in gynaecological surgery, together with the identical previous histories following minor surgical manœuvres—e.g., dilatation and curettage, a 15-minute procedure at a light plane of anaesthesia—prompts one to suggest the cause as embolic from the pelvic veins, and I therefore make the following suggestions.

Anatomically, the left pulmonary artery has a smaller deviation from the line of flow than the right and therefore any solid particle will tend to pass to the left lung, and, in the absence of evidence to the contrary, post-operative infections in the left lung are in the main embolic. Should the work along the lines propounded by Mr. G. W. Vause Greig (October 15, p. 845) ever bear fruit, patients liable to develop this complication could be recognized pre-operatively and the condition prevented.

Infection of the right base is a greater possibility from acute upper respiratory tract infection—e.g., otitis media, sinusitis, and coryza—as droplets and particles of infected mucus will tend to gravitate down the right bronchus owing to its straighter course, aided and abetted by gravity and the absence of the normal expulsive reflexes found during anaesthesia. In practice this type is the most severe, presumably owing to the absence of local pulmonary resistance to the invading organism. The bilateral post-operative infection tends to occur in already infected lungs and is found in the chronic asthmatic and bronchitic and in the heavy smoker.—I am, etc.,

Isleworth, Middlesex. D. F. REES.

Polythene Tubing and Blood Transfusion

SIR,—The article by Dr. W. A. L. MacFadyen (October 22, p. 925) on the administration of heparin by polythene tubing causes me to write to you to say that we have been using this tubing for the administration of blood and intravenous fluids for about twelve months with great success.

We pack up a small tin containing one rubber Record connexion to which is attached about a 3-in. (7.5-cm.) length of rubber tubing to fit on to the Record end of the connexion. Also in the tin is about a yard (0.9 m.) of stout thread wound on a piece of cardboard and a sharp 15-gauge donor-taking needle such as is used by regional blood transfusion teams. The polythene tubing just fits into these needles, and a suitable size can be bought from Messrs. Allen and Hanbury. I would point out, however, that these needles vary, and each needle should be tested with polythene tubing before packing for the autoclave to ensure easy access through the needle.

Before the infusion of blood the polythene tubing is washed well with saline to remove the sterilizing agent. Three ties of thread

are made on the rubber tubing attached to the Record end of the fitting, and the needle is then inserted in the vein in the usual way. The polythene tubing is passed through the needle about 6 in. to 9 in. (15 to 22.5 cm.) into the vein while gentle pressure is exerted by the thumb. The needle is withdrawn from the vein and from the polythene tubing, and after the polythene tubing has filled with blood to expel the air it is then inserted into the small rubber tubing on the Record attachment and the three thread ties are completed. The ties are left long to attach to the arm with strapping to prevent the polythene tubing from "creeping" (it has a tendency to "creep" inwards). The transfusion is then started in the usual way. Complete freedom of the arm is achieved without any alteration in the rate of flow.

I also find that, in the rare event of it being necessary to cut down on the internal saphenous vein, 6 in. to 8 in. (15 to 20 cm.) of tubing can be inserted into the vein like a cannula, and by applying pressure by bandage it is unnecessary to tie off the vein and it is often unnecessary to splint the leg. I would add that the smaller size polythene tubing is found to be unsuitable for blood, as a clot tends to form when infusing "packed cells."—I am, etc.,

Colchester, Essex. ALEC E. BLAXILL.

Pigmentation in Addison's Disease

SIR,—For years the pigmentation of Addison's disease has been explained by assuming that tyrosine, the precursor of adrenaline, accumulates in the skin in the absence of functioning suprarenal glands and is there converted to melanin pigment. This glib explanation, without a shred of evidence in its support, is copied from textbook to journal without questioning, and is repeated by Dr. B. Victor Jones in his paper on acute adrenal insufficiency (November 5, p. 1023). There seems reason to believe that the recent work of Stephen Rothman and his colleagues at Chicago on the mechanism of melanin pigmentation is not so widely known as it deserves.

Briefly it may be accepted that the melanin-forming enzyme in the skin is held in check by various reducing substances, notably sulphydrils and, possibly, ascorbic acid. In order that the enzyme might function it is necessary that the inhibiting action of these chemicals should first be overcome. Lea[1] found that the action of tyrosinase on tyrosine is inhibited partially by certain concentrations of sodium chloride, so it seems possible that the fall of blood chloride in Addison's disease might have some bearing on the pigmentation of this disease. Martini,[2] in a long-neglected paper, found a fall of the blood glutathione in adrenalectomized dogs, and Rivoire[3] and Leobardy and Labesse[4] claimed that by treating patients suffering from Addison's disease with cysteine they caused a marked alleviation of symptoms and a diminution of skin pigment. If these observations are of any significance it would seem that the hypothetical increased availability of tyrosine plays but a small part in a complicated story.

It is noted that the pigmentation of the case described by your contributor appeared within 48 hours of adrenalectomy and almost disappeared after eight days. The known facts about melanin pigmentation make it exceedingly improbable that the pigmentation could have been due to melanin formation. Under the impact of ultra-violet light melanin does not appear macroscopically for a matter of about five days and lasts for months or years. It is unfortunate that a skin biopsy was not taken to determine the nature of the pigment, for the phenomenon must have been a striking one warranting further investigation.—I am, etc.,

Gouty Arthritis

SIR,—Dr. Kenneth Stone in his review of the monograph on rheumatism by Professor Gunnar Kahlmeter (October 8, p. 796) writes: "It is surprising to read that the author has found colchicine of value in rheumatoid arthritis and in rheumatism of the menopause." It did not surprise me to read this. There are many cases resembling rheumatoid arthritis which are definitely gouty. The so-called "rheumatism of the menopause" is perhaps not investigated for uric acid and other clinical manifestations of acute or chronic gout because there is the fallacy, still prevailing, that gout is a rare disease, especially in the female sex.

Although it was accepted some time ago that every case of "rheumatism" should have blood tests for sedimentation rate, uric acid, and Wassermann, I wonder how many practitioners and even clinics perform these tests as a routine. In my experience in South Africa there are very large numbers of "rheumatic" cases in women with a normal or only very moderately raised sedimentation rate and only a small increase in their blood uric acid. In my opinion such cases are definitely gouty and not rheumatoid arthritis. These must be the cases which according to Professor Kahlmeter responded so well to colchicine—a drug which is regarded as a specific for gout.

The debatable point is the figure for normal blood uric acid. Unless we agree on a certain figure obtained by a certain method which may be regarded as normal (and the same must be said about the sedimentation rate) we cannot come to any amicable settlement at all. May I suggest that the next international rheumatic congress makes a serious attempt to agree on certain uniformity and criteria in laboratory and clinical investigations of the so-called "rheumatism and allied conditions"? This would be of definite benefit to our suffering patients.—I am, etc.,

Johannesburg. NATHAN FINN.

Prostatic Obstruction

SIR,—The article by Mr. H. Hamilton Stewart on prostatic obstruction (November 5, p. 1011) mentions calibration of the anterior urethra by direct measurement. I wonder whether it would be of interest to recall that a similar instrument was used by Otis in America towards the middle of the last century. He made the then very important discovery that the male urethra is of very much larger calibre than was realized, and his findings enabled Bigelow, then professor of surgery at Harvard, to make lithotrites and evacuating cannulae of sufficient size to put the operation of litholapaxy on a practical basis.

An illustration of a urethrameter is to be found in Sir Peter Freyer's book, *Stricture of the Urethra and Enlargement of the Prostate* (London, 1902, p. 18), and he comments that its use is made a little difficult by a tendency for the blades to catch in the urethral mucosa. In the same book (p. 13) is a reference to still earlier work on the subject, that of Sir Everard Home, who measured the urethra by making a cast of it in the cadaver, and an outline of one of these casts is reproduced.—I am, etc.,

Swansea. B. BRENDAN HICKEY.

Myoidema

SIR,—The article on myoidema by Colonel Geoffrey F. Taylor and Dr. P. N. Chhuttani (October 8, p. 784) interested me greatly. I feel that my experiences may be of interest, as they appear to support their contention as to the factors which lead to its production. I trust that I may be allowed to place them on record.

Until starting practice in South Africa I had always regarded the elicitation of the presence of myoidema (as defined in the article) as an indication for a careful clinical examination. It was a sign which I looked for early in my examination and which, when present, I regarded as an indication of ill health. Frequently I found it associated with tuberculosis, malignant growths, or other serious disease. Only when all other indications of disease were absent and I was satisfied did I dismiss it as of no serious import. On several occasions the sign has prevented my overlooking serious disease.

My clinical practice prior to arriving in South Africa had been restricted more or less to Europeans, mainly from Britain, whose diet was relatively good, even among the poorer groups of the population. I now practise in the Transkeii, a native reserve, and the bulk of my patients are natives. Malnutrition is general, pellagra of frequent occurrence, and nutritional oedema in children in times of drought and starvation common. The causes for malnutrition in the native are well known to all

control of drug sensitization reactions

with ANTHISAN® mepyramine maleate

The patient sensitized to penicillin, and to liver and insulin preparations, need no longer be deprived of the benefit of these essential drugs. The administration of ' Anthisan ' normally gives adequate control of symptoms and enables the treatment to be continued.

Failure to respond satisfactorily to ' Anthisan ' is an indication for the substitution of the more powerful antihistaminic ' Phenergan ' brand promethazine hydrochloride which extends the benefits of antihistaminic therapy to the patient whose allergic state has exhibited resistance to other drugs.

Supplies: ' ANTHISAN '

Containers of 25, 100 and 500 x 0.05 Gm. and 0.10 Gm. tablets.

Containers of 4 and 80 fl. oz. Elixir.

THE PLACE OF *Pertussis Vaccine* IN ROUTINE PROPHYLAXIS

Investigations in the Glaxo Laboratories have established criteria for the selection of strains of organisms and for methods of growth which result in a pertussis vaccine giving highest immunological response . . .

A vaccine prepared in accordance with these standards is incorporated in Diphtheria-Pertussis Prophylactic *Glaxo*—a preparation affording the convenience of combining pertussis immunisation with routine diphtheria preventive measures. Three injections are advised for primary immunisation—0.5 cc., 0.5 cc. and 1 cc. at 4-weekly intervals. For pertussis immunisation alone, Whooping Cough Alum-Precipitated Vaccine *Glaxo* is now widely employed, containing 20,000 million H. pertussis in each cc.

'PERNIVIT' FOR CHILBLAINS

Tablets of Acetomenaphthone B.P. and Nicotinic Acid B.D.H.

'Pernivit' is a scientifically formulated preparation combining nicotinic acid and acetomenaphthone (vitamin K analogue), both of which used separately have proved to be of considerable value in the treatment of chilblains. There is evidence that 'Pernivit' combines the effectiveness of both; it utilises the vasodilator properties of nicotinic acid and the effect of vitamin K in maintaining normal blood coagulability and vascular permeability. Itching and inflammation are quickly relieved following the administration of 'Pernivit.'

'Pernivit' is available in bottles of 50 and 500 tablets.

Literature and samples will be forwarded on request

administrative, medical, and welfare workers who deal with him. They embrace poor husbandry, soil erosion, ignorance and apathy, impact of civilization, economic disadvantage, etc. Maize forms the bulk of the native diet. Milk, meat, eggs, corn, and beans are also eaten, but in many cases the amount is small, especially during drought and starvation.

It was not long before I ceased to regard the elicitation of myoidema in the native as an indication of serious disease. It was present too frequently, and I tentatively put this frequency down to the native's nutritional state. The deficiency diseases which predominate in times of stress are those associated with the vitamin-B complex, and it is not unreasonable to attribute the high incidence of myoidema to a deficiency of one or more members of this complex.

Nevertheless the conclusion that myoidema is due to a local nutritional deficiency of muscle should not bring it into disrepute as a clinical sign. There may be more than one cause for this local nutritional state. Its presence in an individual known to come from a group normally well nourished should be regarded as a sign of possible serious disease until proved otherwise.—I am, etc.,

Tabankulu, South Africa. J. H. JACKSON.

The Acute Throat

SIR,—I notice in the *Journal* of November 5 (p. 1048) a letter from Mr. W. Stirk Adams with reference to the treatment advocated by Professor Wilkinson and himself in the *Birmingham Medical Review* (1947, 15, 170). As regards penicillin treatment, being a G.P. I have never used this by injection, nor have I seen any useful result from penicillin lozenges. Sulphonamides, especially sulphamezathine, have given good results, but in my opinion the treatment *par excellence* is by bismuth and sodium tartrate suppositories three times daily. I have employed these in between 40 and 50 cases, and with only one exception the improvement has been rapid and cure complete in two to three days.

In two cases where there was obvious pus formation in the peritonsillar tissues it was, of course, obvious that this would need to be evacuated, but I prescribed the suppository to see whether the pain was eased. In each case the patient informed me that relief was rapid and marked.

In ordinary cases of follicular tonsillitis several patients have remarked on the rapidity with which the suppository acts, stating that within half an hour the throat became much easier. Patients have been between 3 and 65 years of age. I have never seen any undesirable effects, even when suppositories containing 1 gr. (65 mg.) of the salt have been used in young children of 3 or 4 years. But for safety I have had suppositories containing gr. ¼ (16 mg.) made up for small children. In no case have more than six suppositories been needed, and the saving of pain and time to the patient and of time to the doctor make this to my mind a most valuable line of treatment.—I am, etc.,

Solihull, Warwick. C. T. MATTHEWS.

SIR,—Dr. T. Anderson (October 15, p. 860) has written a very practical and valuable article on the acute throat. There was an omission, however, which I feel merits recall. In discussing the treatment of the anginose type of glandular fever, no mention was made of the use of intravenous arsenic, which some years ago received high praise from Smith and Shaw[1] for its value in dealing with the occasional intractable and severe angina occurring in that infection. I have, since that publication, found a similar response in anginose glandular fever even in the absence of fuso-spirillosis and where there had been a failure to respond to other therapy, including penicillin. The drug is usually given in a single dose of from 0.3 to 0.45 g. intravenously, according to the weight of the patient.—I am, etc.,

London, S.W.6. W. HOWLETT KELLEHER.

A Long Gestation

SIR,—Dr. Madeline N. Gors (November 5, p. 1049) raises an interesting subject when she discusses the origin of folk tales dealing with long gestation periods. These myths are very common, and the suggestion that they arise from the practice of a man marrying his deceased brother's wife has been made before. This custom—technically known as the levirate—is widespread, but serious anthropological objections can be offered to the suggestion that it may be the origin of these myths. In the first place, other marriage systems such as the sororate or ghost-marriage of the Nuer type might equally well be advanced to account for such tales. Secondly, the expected results of this theory conflict with certain observed practices in various endogamous and exogamous groups. Thirdly, if this theory were correct certain significant correlations would be expected between the observed distribution of the levirate and the distribution of the bradycyesis myths. These correlations are not significantly found.

An attempt has been made to derive the myth from animal totem beliefs on the basis of the unknown length of many animal gestation periods. This attempt has not been very successful. Another theory links it with giant and longevity stories: where a culture-heroine is credited with a life of five hundred years she may reasonably expect to spend six years carrying a child. A further explanation has been sought in the occurrence of such conditions as foetus papyraceus and lithopaedion.

At present it does not seem possible for anthropology to offer a solution of this problem. Whatever the origin of the belief, however, there is no doubt that it is psychologically very acceptable to peoples of many different culture patterns.—I am, etc.,

Treatment of Basal-cell Carcinoma

SIR,—It was with great interest that I read the paper on this subject by Sir Cecil Wakeley and Mr. Peter Childs (April 30, 1949). Most people now recognize that Australia has the unenviable reputation of having the highest incidence in the world of skin and lip carcinoma. The reason for this (chronic sunburn effect in a fair-skinned population largely engaged in outdoor occupations) has been discussed elsewhere by myself[1] and other Australian observers. Sir Cecil Wakeley bases his experience on 237 cases seen over the course of 35 years. During my tenure of office at the Royal Prince Alfred Hospital, Sydney, the total of 237 cases of basal-cell carcinoma was greatly exceeded each year, especially if the many cases seen and treated by me in private practice are included.

The distribution of lesions in Sir Cecil Wakeley's collection of cases (214 on the face, scalp, and neck to 23 on other parts of the body not exposed to sunburn) is understandable, as in England there will be a larger proportion of basal-cell carcinoma due to other causes than ionization by the ultra-violet component of sunlight. In Australia the proportion would be at least 100 on exposed to one on unexposed areas.

There are a number of points in Wakeley and Childs's paper upon which I must express strong disagreement. First, I wish to point out that surgical intervention is highly inadvisable as treatment for basal-cell carcinoma on the edge of the lower lid, in that awkward corner just medial to the inner canthus and over the lacrimal sac, and in comparatively advanced lesions over the course of the facial nerve. Yet by local anaesthesia in the conjunctival sac and the insertion of a lead spatula under the diseased lid, these lower lid tumours (which are not so uncommon) can be easily and most efficiently treated by *x* rays without any possible damage to the eye, leaving only a very shallow bay on the edge of the lid and without any impairment of the wiping apparatus. The technical difficulty in treating by radiation the deeper growing basal-cell carcinoma is trifling if the operator is reasonably experienced. Of course radiation treatment is not standardized in the strictest sense any more than surgery is. But to all competent radiologists the dose in r units with allowance for fading effects is standardized.

In my experience the number of recurrences after surgical excision by competent surgeons notably exceeds those after irradiation by competent radiologists. Moreover, a competent radiologist, like a competent surgeon, can easily appreciate the surface extent and depth of penetration of a basal-cell carcinoma and allow a sufficient margin of apparently healthy tissue round and beneath the growth.

I cannot agree that "irradiation produces radiodermatitis," at least in doses suitable for the cure of basal-cell carcinoma. In certain cases which have been rendered radio-resistant by previous timid and inadequate dosage requiring too many repetitions radiodermatitis may occur, but the competent and experienced radiotherapist will rarely undertake such cases after they have been spoiled by previous tinkering by some inexpert operator. If it does occur the surgeon can excise it and graft the area if necessary with little or no more difficulty than if he were operating on the original tumour.

The use by Wakeley and Childs of the phrase, "Only rarely need a patient be *condemned* to irradiation," surely proclaims an ineradicable prejudice against radiation on the part of the authors. Without the support of any authority they state, "Recurrences occur *consistently* in 5% of cases treated by *x* rays." By the context this must be applied to cases of basal-cell carcinoma. If this is their experience they must have been most unfortunate in their choice of radiologists. If one excludes very advanced cases such a figure is very misleading. In my experience recurrences are less than 1%, and one can say with confidence that nearly all these are marginal recurrences due to the inclusion of too small a margin of apparently healthy skin around the tumour. Such recurrences are quite easily manageable by further irradiation excluding the previously treated area. With proper technique and dosage there should be no recurrence of basal-cell carcinoma after *x* rays or radium treatment any more than after "adequate surgical excision."

With regard to "time lost to work, admission to hospital, and mental trauma," I am bound to insist that "the advantages" definitely lie with radiotherapy. There is a very potent psychological factor which is entirely overlooked by Wakeley and Childs. Before it is possible to make arrangements for "premedication of patients to diminish their worry" it is necessary to persuade them to submit to an operation. The early stages of basal-cell carcinoma and even of a squamous carcinoma are so insignificant to the layman's eye that if nothing but surgery is offered to him he will procrastinate, perhaps till too late. The operation which seems trivial and safe to the surgeon looms large in the mind of the patient. He and his friends will probably conclude that the doctor is an alarmist, and he will "wait and see." This was frequently observed in Australia when for the first five years of this century the only form of treatment available was surgical excision. I and my contemporaries in those days saw dozens of hideous cases with deep invasion of bone, exposed antra, etc. Since radiation has entered the field such horrible cases are no longer seen because the patient does not regard *x*-ray or radium treatment as an operation."

The secretary of the Royal Prince Alfred Hospital, Sydney, has at short notice located 1,247 cases of basal-cell carcinoma treated in the superficial *x*-ray department in the year 1947–8 besides 50 cases treated as in-patients and others treated in the radium clinic. Almost all of these are referred to the skin department, the doses being prescribed generally by the officers of that department. I realize that these figures will appear exaggerated in the eyes of practitioners in the British Isles. But if any one of these who is interested in skin carcinoma come out here and see for himself. I believe, after a close study of skin carcinoma and a huge experience of cases of this disease and its treatment, that the suggestion made by Wakeley and Childs that all cases of basal-cell carcinoma should be treated surgically means an attempt to put the clock of progress back nearly 40 years.—I am, etc.,

Sydney, Australia. E. H. MOLESWORTH.

Pulmonary Embolism in General Practice

SIR,—It is now widely accepted that the correct treatment for pulmonary embolism is immediate administration of heparin. Various other methods are advocated as additions to this treatment, but the heparin administration maintains its position as the sheet anchor. The earliest moment at which heparin can be given to a patient with recent pulmonary embolism is the best moment for its administration. I should like to make a strong plea for general practitioners to include heparin as part of their emergency kit, so that they may administer an intravenous dose of 10,000 units (international) of heparin immediately they see a case of suspected pulmonary embolism in their practice. In this way they would be able to cut short the retrograde thrombosis occurring after the embolism has reached the lung. They would also give themselves a great deal more satisfaction by feeling that the patient was not likely to develop any further extension of thrombotic phenomena during transit to hospital. Best of all, they would have the joy of seeing the initial severe pain checked in a most dramatic way in many cases. One such dose, even if the diagnosis was inaccurate, would do no harm and would be sufficient to cover four hours, during which the patient would become fit for removal as the initial shock phase passed off.—I am, etc.,

Mauchline, Ayrshire. G. J. CLELAND.

Synovial Osteochondromatosis

SIR,—The excellent article by Mr. J. F. Curr (November 5, p. 1020) in which he states that synovial osteochondromatosis is very rare in the shoulder-joint prompts me to record the following case.

A young married woman of 23 was first seen on August 25, 1947, complaining of stiffness in her left shoulder-joint for one year. The onset was slow, there had been no injury or rheumatism, and she was then unable to raise her arm above shoulder level. On examination she was a very healthy woman apart from the trouble in her shoulder. Behind the joint there was some fullness and a bluish discoloration of the skin. The movements were limited in all directions below 90°, but these were only slightly painful, and indeed pain had never been a prominent feature. Palpation of the diffuse swelling behind the joint gave the feeling of fine crepitus; and there was slight local tenderness. *X*-ray examination of the left shoulder showed a deformed left glenoid: "arthritic changes in joint due to large calcifying osteochondroma arising from the glenoid region." A radiograph of the right shoulder was normal, the lung fields clear, and the E.S.R. 10 mm. in one hour. A further stereoscopic radiograph showed that the tumour was lying almost entirely behind the joint and was displacing the base of the coracoid medially. A diagnosis of diffuse osteochondromatosis of the synovial membrane of the left shoulder-joint was made, and the patient was admitted for operation on February 13, 1948, having requested delay until her husband arrived from abroad. At this time there was almost complete absence of true shoulder movement (flexion 25°, extension 30°, abduction 15°). General muscle-wasting was present, particularly the deltoid, and fullness at the back of the joint due to a palpable firm tumour. There was still very little pain.

At operation a posterior approach was made and the deltoid reflected up, the incision being carried through the infraspinatus muscle. A firm tumour attached to the capsule of the shoulder-joint posteriorly was opened and multiple firm loose bodies about the size and consistency of dried peas were scooped out. Many were lying free, but others were attached by a short pedicle or were embedded in the synovial lining. Over 100 of these cartilaginous bodies were removed, together with the redundant synovial diverticulum, and the capsule was resutured. Section of one of the loose bodies showed rapidly growing cartilage cells.

Recovery was straightforward. The patient was given physiotherapy over the next four months, with considerable improvement in the range of movement (extension 125°, abduction 90°). A radiograph taken eight months after operation showed a few fragments of the osteochondroma high up in the joint below the acromioclavicular arch, and the osteoarthritic condition of the joint was unchanged. When last seen on October 20, 1949, she had almost full movements of her left shoulder-joint, which was painless and without evidence of any recurrence of her tumour.

I am indebted to Dr. W. A. Steel for the operative findings and permission to publish this case.

The Nature of Lumbago

SIR,—Your annotation on lumbar "fibrositis" (September 24, p. 695), in dealing with the pathology of this condition, reflects the prevailing agnosticism on the subject. An excellent lead to the understanding of it is however given by Elliott,[1] who showed that myalgic nodules gave electrical discharges, as recorded by an oscillograph, identical with those given by muscle spasm.

The leading features of lumbago are that it is usually of sudden onset and is the result of a strain, either internal, such as coughing, sneezing, or parturition, or external, such as lifting a heavy weight when the body is bent forwards. Pain, often of great severity, then occurs in the erector spinae group of muscles, especially when movement is attempted, and these muscles are tender to palpation. Tenderness is also usually present over the sacro-iliac joints, and this may be elicited as follows: (1) by percussion over the posterior superior iliac spine; (2) by pressure upwards into the sciatic notch; (3) by deep palpation in the iliac fossa over the anterior border of the joint; (4) by palpation of the anterior border of the joint on pelvic examination.

The manipulation for low backache which I described in my letter (September 24, p. 710) is effective in cases of lumbago. In unilateral cases the manipulation is done on the one side only. In bilateral cases both sides are manipulated. In the past year the following results have been obtained by this method:

Cases manipulated (unilateral cases eight, bilateral cases 18)	26
Immediate abolition of the pain	26
No recurrence	14
Recurrence	12

The final state of the recurrent cases was:

Recovered after a second manipulation	2
Allowed to recover spontaneously	5
Considerable improvement	1
No improvement	4

Two cases had to be allowed to recover spontaneously because the manipulation failed when applied a second time. The four cases which did not improve had all had lumbago for many years.

That the manipulation acts on the sacro-iliac joints (*pace* Dr. Trevan Hambly, whose letter you published on October 15, p. 874) is suggested by the fact that the sacro-iliac joints are tender, that the condition is often bilateral and the two sides are manipulated separately, and that whenever crepitus or other noise or sensation accompanies the manipulation it appears to emanate from the sacro-iliac joints. The manipulation may possibly act also on other joints in the lower part of the back or may possibly reduce a herniated nucleus pulposus, since Burns and Young[2] demonstrated that such herniation may be pushed back at operation.

Lumbar fibrositis therefore appears to be nothing more than spasm in the erector spinae group of muscles, usually the result of a manipulable lesion in the sacro-iliac joints and is comparable with the spasm around a dislocated shoulder-joint, which also disappears at once when the dislocation is reduced without anæsthesia. The popular term "lumbago" includes the cases of lumbar "fibrositis" discussed above and also cases of severe low backache without marked involvement of the erector spinae muscles.—I am, etc.,

Botulism or Polio-encephalomyelitis?

SIR,—I was most interested to read of the case of botulism described by Dr. David Kendall (November 12, p. 1094). It seems to me, in the light of current events, that the combination of cranial-nerve palsies with bulbar involvement, pyrexia, vomiting, residual weakness of the dorsiflexors of the ankle, and even survival is more likely to be caused by an attack of polio-encephalomyelitis, which has now become so common, than by botulism, which is so rare.

I think that it is unfortunate that too much attention has been focused on the ingestion of canned tongue and that this has served only to mislead. The clinical picture so ably described by Dr. Kendall is to be seen all too frequently in those hospitals where acute cases of infantile paralysis are admitted. It is well known that the protein content of the cerebrospinal fluid rises during the third week of an attack of poliomyelitis: though Dr. Kendall saw the case at a late stage, I think that lumbar puncture might have revealed this phenomenon.—I am, etc.,

E. VIVIAN LAMBERT.

Uxbridge, Middlesex

SIR,—I have read with interest the report by Dr David Kendall of a case of "botulism" (November 12, p. 1094), but I feel that from the epidemiological point of view there must be some considerable doubt about the diagnosis. It seems to me to be very surprising that, if the tin of tongue contained botulinum toxin, only one of those who ate it should have had an illness involving the cranial nerves. Botulism is the nightmare of manufacturers of canned foods, and in commercial canning processes great care is taken to ensure that foods which are a suitable medium for *Cl. botulinum* are heated to a temperature which will kill the spores.

I hesitate to enter into a discussion of the clinical features of the case, but have just re-read the official account of the outbreak at Loch Maree in 1922, and it does seem to me that the clinical picture was very different in this case from that described in the report. I suggest that the possibility of some other diagnosis should be considered.—I am, etc.,

Death by Hanging

SIR,—It is often said that death by hanging is "instantaneous." What is the evidence for this statement? The following might be causes of unconsciousness: (1) Concussion when the rope breaks the fall. (2) By nervous impulses originating in or near the crushed cervical cord. Both (1) and (2) seem improbable. (3) By compression of both vertebral and both internal carotid arteries; this could hardly be predicted with certainty. (4) By immediate asystole; this, if it occurred, would lead to unconsciousness in about six seconds. It may not occur, for people have survived compression of the cervical cord. (5) By loss of vasomotor tone and consequent inadequacy of the cerebral circulation—a slower process than the last. (6) Fall of oxygen tension in the blood; this factor by itself would produce unconsciousness in a matter of minutes.

Many medical men besides myself must have an uneasy suspicion that the last two factors are the cause of unconsciousness and death from hanging, and that the subject may remain conscious for many seconds after the drop.—I am, etc.,

Memorial to Sir John Fraser

SIR,—Some months ago (August 13, p. 389) you granted us the courtesy of your columns to announce the opening of a fund to establish a memorial to the late Sir John Fraser, Bart., K.C.V.O., formerly regius professor of clinical surgery and principal of Edinburgh University.

It is our intention to close the fund on December 3, and those who may still wish to contribute are reminded that subscriptions should be sent before that date to the treasurer, John Bruce, Esq., C.B.E., F.R.C.S.Ed., Department of Surgery, The University New Buildings, Edinburgh.—We are, etc.,

Firework Injuries

SIR,—Shortly after reading the annotation entitled "Burns and Bonfires" (November 5, p. 1033) I was called, on Guy Fawkes' night, to operate on a boy of 12 who had a severe injury to his right hand. Another boy had lit a firework; it fell over, and this boy picked it up and it "exploded" in his hand. Half the thumb was blown off; the metacarpal, with its muscles hanging loose, was held by a flap of skin. The index finger was badly injured and fractured, and the palm opened up right down to the carpal bones, at least one of which was fractured. Muscles and tendons were torn and charred. One hopes that conservative surgery may save most of the hand and give some, but not normal, function. Such injuries to the thumb and index finger of the right hand in a boy are a big price to pay for an evening's enjoyment.

Your annotation rightly mentions that most of these firework accidents could be prevented if common-sense precautions were taken, but children in the excitement of the moment do not always remember these. Also the instructions on the firework cannot be read in the dark. I would suggest that the makers might distribute two distinct classes of firework: harmless ones for children, and a more powerful type for adult use. The children's fireworks would be such that no serious damage could occur even if they "go off" in the hand, and it would then be up to the parents to see that their children purchased this type only.

Your annotation also states that the medical profession, since it is aware of the dangers, has a responsibility to make them known and so prevent these injuries occurring. My impression is that these injuries are much more common than we imagine, but I have never seen any statistics about Guy Fawkes' night casualties. I should be interested to hear of similar accidents to this one (where some permanent disability is likely to remain) which have occurred this year, and would be obliged to any surgeon who could send me brief details of such cases. In this way we may be able to do something to prevent these rather unnecessary war-like injuries.—I am, etc.,

L. A. H. SNOWBALL.

Wakefield House,
Compton Street, Eastbourne.

POINTS FROM LETTERS

Pronunciation of Chemical Terms

Dr. W. BRYCE ORMB (Hove, Sussex) writes: Doctors and chemists are aware that difficulties occur in reaching consistency in the pronunciation of certain chemical terms, such as benzene and benzine, but generally it is conceded that the former should be rendered as ben'zēn and the latter ben'zin. It was, however, a shock to hear several highly qualified and distinguished chemists at a well-known pharmaceutical laboratory all referring to the radical CH_3 as mēthyl. I had the temerity to correct them and pointed out that the term was derived from the Greek μεθυ = wine + ὑλη = wood. . . . Neither Dorland's *Medical Dictionary* nor our old school friend, Liddell and Scott's *Lexicon*, refers to any latitude in the pronunciation of methyl.

Recovery of Drugs from Urine

Dr. G. D. WILD (Derby) writes: The cost to the nation of such drugs as penicillin, streptomycin, and P.A.S., etc., must still be very great. I believe they are all very largely excreted by the kidneys, either unchanged or only very slightly modified. There appears to be no revulsion from the use of drugs prepared from urine of pregnant mares. I consider the recovery of valuable drugs (costly even when they cease to be in short supply) from the urine of human and veterinary patients affords a chance to economize which should be seriously considered at times like these present.

Cigarette Cough

Dr. D. A. HERD (Leeds) writes: I was pleased to read the letter (October 15, p. 876) on cigarette cough by Dr. B. J. Gallighan. When discussing this very important subject with patients, they frequently tell me, "But I never inhale." Now this statement is sheer nonsense, for although they do not pull the smoke through the cigarette they, and others in the vicinity, are compelled to inhale the surrounding contaminated atmosphere. This fact is proved beyond doubt by the intense discomfort experienced by victims of asthma and bronchitis. I entirely agree with his remarks about the cinema and theatre, but are not the majority of smokers inconsiderate?

Obituary

T. P. McMURRAY, C.B.E., M.Ch., F.R.C.S.

We announce with deep regret the sudden death of Professor T. P. McMurray, President-Elect of the British Medical Association. Professor McMurray, who died at Ealing Broadway station on November 16, at the age of 61, had been Professor of Orthopaedic Surgery in the University of Liverpool since 1938. He had been staying with his son-in-law and daughter and had intended to go on a visit to South Africa.

Thomas Porter McMurray was born in Belfast on December 5, 1887. He was educated at the Belfast Academy and at Queen's University, where he graduated M.B., B.Ch., B.A.O. in 1910. In 1919 he proceeded to the degree of M.Ch. and he took the F.R.C.S.Ed. in 1923. He was elected F.R.C.S. by the English College in 1948. Soon after qualifying McMurray was appointed house-surgeon, and later surgical tutor and registrar, at the Royal Southern Hospital, Liverpool. There he came under the influence of the late Sir Robert Jones and decided to devote himself to orthopaedics. He was appointed honorary orthopaedic surgeon to the David Lewis Northern Hospital in Liverpool in 1913, and in 1914 he was commissioned as a captain in the R.A.M.C. He had, however, only a brief period in France. He was recalled to spend most of the war at the Orthopaedic Centre at Alder Hey, where Sir Robert Jones was responsible for the treatment of cases and for the training of English, Canadian, and American surgeons. McMurray's connexion with Alder Hey Hospital, which began in 1915, was to continue for the rest of his life. He served for an even longer period the Royal Liverpool Children's Hospital, with which he was associated just before the outbreak of the 1914–18 war. Originally appointed as an honorary surgeon, he became honorary orthopaedic surgeon to this hospital in 1919. He acted as consultant for the Ministry of Pensions from 1920 onwards, and from 1933 he was orthopaedic consultant to the Lancashire County Council.

[*Bacon, Liverpool*

McMurray was appointed lecturer in orthopaedic surgery at the University of Liverpool in 1924. In 1933 he became director of orthopaedic studies, and when a chair was established in 1938 McMurray became Liverpool's first professor of orthopaedics. He had been president of the British Orthopaedic Association in 1940–1 and president of the Liverpool Medical Institution in 1948. He was president of the Section of Orthopaedics at the Cambridge meeting of the British Medical Association in 1948. He was awarded the C.B.E. in 1946.

Professor McMurray published many papers and a number of books, of which perhaps the best known were his *Life of Hugh Owen Thomas*, which appeared in 1935, and *A Practice of Orthopaedic Surgery*, which followed two years later. All his writings are simple and clear to the

ANAESTHETICS

'TRILENE'—in addition to its use in analgesia—is employed with success for the production of a light plane of anaesthesia. Contra-indications are few, and recovery is rapid with no unpleasant after-effects.

Containers of 250 and 500 c.c. Crushable ampoules of 1 c.c. in boxes of 5; ampoules of 6 c.c., boxes of 1, 5 and 25.

'KEMITHAL' SODIUM is a highly efficient ultra-short-acting barbiturate used for induction and surgical anaesthesia of short or prolonged duration. Notable features of its use are minimal respiratory depression and a consistently good post-operative recovery, free from vomiting, restlessness and protracted depression.

Ampoules of 1 or 2 grammes, with or without distilled water. Containers of 5 and 25.
Ampoules of 5 grammes, without distilled water. Containers of 5.

Other anaesthetics and analgesics include: 'Avlon' brand Chloroform, Procaine, and Pethidine (with and without Hyoscine).

point of being dogmatic. They reflect his teaching methods, which were direct and penetrating, though not unrelieved by humour.

A glance at McMurray's record will convey some idea of his experience, but it cannot reveal the uncanny instinct which guided him in diagnosis, in treatment, and also in knowing where to draw the surgical line. For instance, some of his colleagues will recall, in the early days of his displacement osteotomy, an occasion when the first blow of the osteotome shivered into bits the whole upper end of the femur. "That," said McMurray, "will be fine," and he stitched up immediately. The end-result was perfect. Watching him operate induced mixed feelings of pleasure and humility. A surgically beautiful pair of hands, perfectly co-ordinated with the directing brain, carried out operations the approach to which was as direct and purposeful as the performance was clean and swift.

It was typical of McMurray that in May, 1941, the destruction of 11, Nelson Street with all its orthopaedic treasures provoked no more than a snort of irritation. The German bomb destroyed his rooms, his instruments, and his unique mementos of his predecessors, but its only effect on McMurray's implacable spirit was to harden it. Although the list of honours accorded to him by his fellows indicates his status in the medical profession, distinctions were not sought by him. Two years ago many of his former students were gathered together to pay tribute to McMurray on his retirement from the chair of orthopaedic surgery at Liverpool University and to present him with a hand-made book containing signatures and portraits of his old students. To those who knew him well it often seemed that McMurray derived more pleasure from this book than from the many distinctions that came his way. The words inscribed by the donors of this book are worth recalling: "This book is signed and presented by your old students as a symbol of their respect and affection and to record for ever the debt they and their country owe to you. By your skill and by your teaching you have enhanced a great tradition this is now our treasured heritage and by our deeds we will preserve it."

Sir Henry Cohen writes: The rise of orthopaedic surgery to a major specialty in this country owes much to two world wars and to the increasing mechanization of industry and transport, but it owes most to the calibre, vision, and zeal of those who have been pioneers and leaders in this field. Among these we in Liverpool recall with gratitude and pride Hugh Owen Thomas, Robert Jones, and T. P. McMurray, whose sudden passing a few days ago stunned us with grief. It is over a quarter of a century ago that, as a dresser, I first met this tall young surgical teacher, of attractive and imposing presence, intent on imbuing his students with the importance of orthopaedic surgery. In didactic method he favoured the dogmatic and was somewhat impatient of the Socratic. He criticized fearlessly the incompetence in the treatment of fractures and skeletal injuries of many of his "general" surgical colleagues. Indeed, his outspokenness freed him from the dangers of that peril of which, on high authority, we are warned to beware, when all men speak well of us. But it was as a colleague, both in practice and at the University, after he succeeded his master and mentor, Robert Jones, as director (and later as professor) of orthopaedic surgery that I came to know him best in the intimacy of his home and his family and in University and hospital administration. He mellowed but little as the years advanced. He still exposed our faults and errors, though with complete sincerity, and I believe he would have been both hurt and surprised if he had known that some of his remarks were taken amiss. In committee he sometimes provoked by a veneer of cocksureness, but his views were generally right. He was not a polished orator, but he had a ready wit and could rebut the small facetiousness with a pungent thrust.

To his orthopaedic students and colleagues he was at once an example, a stimulus, and an inspiration. He handled the injured part with meticulous care and extreme gentleness. He never failed to preach that he was a servant, not the master; that in his hands lay the power not to heal but to help healing; that Nature was the great healer. No one exemplified more perfectly the precepts of Ambroise Paré. He was impatient of those who introduced operations hoping for eponymous fame when he knew that simple measures in his hands yielded even better results. No one applauded more heartily the quip that many orthopaedic surgeons published operative "cures" in 100% of cases in an apologetic tone which suggested that they hoped to do better next time. For him the aim of therapy in orthopaedics was to get the best out of the natural defensive mechanisms and healing powers of the body, and to eschew the spectacular and dramatic. Yet he was himself a superb craftsman; he had no superior in operative skill and no one could make an operation look more like a work of art.

His associations with Robert Jones and the Liverpool school, and his outstanding skill, brought him a very large practice. But he did not prostrate his gifts to the service of Mammon; he used them for the benefit of his fellow men in all stations of life, and by that measure of a man's height in the sight of humanity McMurray's stature was indeed great. Others will write with greater knowledge of the gifts which he brought to the principles and practice of orthopaedic surgery, but I believe that history will record that his greatest contribution lay in his keeping brightly burning the torch handed down by Robert Jones, so that through the hundreds of students trained in the Liverpool school, many of whom now adorn the major teaching centres and great hospitals not only of this country but of the world beyond, the crippled and the disabled have been given greater hope. Of him it can with truth be written that "his way was known upon earth and his saving health among all nations."

Sir Harry Platt writes: The sudden and unexpected death of T. P. McMurray has come as a shock to his friends and contemporaries, and his passing will be mourned by a great concourse of pupils now scattered throughout the Commonwealth. For "Mac," or "T.P.," as we called him, bore his years lightly; his youthful appearance was always a source of comment wherever orthopaedic surgeons met together in conference. His death marks the end of a chapter in the story of the evolution of orthopaedic surgery in Great Britain, and, indeed, in the English-speaking nations. Since the retirement of McCrae Aitken, McMurray had represented the last direct and intimate link with the teaching and practice of Sir Robert Jones. McMurray was Robert Jones's private assistant during that period of amazing activity which characterized the seventh decade of the life of that great master surgeon. It was for "Mac" a time of quiet self-effacement, but during those years of unique experience he laid the foundations of that clinical wisdom which later was his outstanding attribute as a teacher and leader of young men. McMurray, as a true son of Ulster, was unswerving in his devotion to a cause, and he felt impelled to enunciate the truths in which he believed; like Luther, he "could do no other." In his later years what appeared on first acquaintance as an uncritical and uncompromising acceptance of the doctrines of H. O. Thomas as self-evident and eternal verities repelled many of the restless spirits among the younger generation of orthopaedic surgeons on both sides of the Atlantic. His resistance to the ever-increasing practice of wedding metal to bone, and to the urge to cut short the long-term diseases of the skeleton in the evolutionary stage by early operative intervention, had persuaded them that he had become an old-fashioned and doctrinaire advocate of outworn principles. Few realized that the dogmatic Ulsterman was essentially a tolerant man, and that his philosophy was "Live and let live." He taught the value of conservative methods not because he himself was indifferent to the lure of the operating theatre—few surgeons of his generation in any field could compete with McMurray in sheer manual dexterity. His innate skill as an operator was manifest at a very early stage in his career. I well remember an occasion at the Alder Hey Military Hospital during the first great war. He was then in

his thirty-first year, and in the large audience in the operating theatre there were many experienced surgeons from the Dominions and the United States. McMurray picked up a scalpel, poised it for a moment in the air, and with one artistic sweep made a long incision accurately over the line of the ulnar nerve in the upper arm. This was followed by a second perfectly executed cut which divided the deep fascia covering the nerve trunk above and below the site of lesion. There was a murmur of admiration from the spectators.

In a long unbroken friendship with McMurray, with our careers running parallel in university cities not more than thirty-five miles apart, I cannot recall any occasion of misunderstanding or any feeling that we were rivals. When Robert Jones turned to me for help in the formidable task of preparing a second edition of Jones and Lovett, "Mac" showed no trace of resentment. He recognized with his essential generosity of spirit that others could also serve our great leader—each in his own fashion. McMurray's lasting personal contribution to his surgical generation was the building up of the great postgraduate school of orthopaedics in Liverpool associated with the M.Ch.Orth. degree of that University. The recognition of that great achievement by his elevation to professorial status was a source of pride not only to him but to his many colleagues and former pupils. Before I bring this tribute to the memory of my colleague to a close, I must refer to his uprightness and above all to his courage. He bore the tragic death of his first wife with great stoicism; and for some years he was a very lonely man. His second marriage brought him a new contentment, and in their country home in Denbighshire many years of happiness in retirement seemed to stretch out before him.

Sir Reginald Watson-Jones writes: Until recent months T. P. McMurray was still teaching postgraduate orthopaedic students and saying: "Feel it, laddie"; "I think you're splendid"; "Get on with it, laddie"; "You're a credit to us." Last week at the Hugh Owen Thomas Lecture in Liverpool he welcomed "a lost sheep" back to the fold; and in London he was planning his presidency of the British Medical Association. The suddenness with which we have lost an alert vitality, a boyish good humour, and a tall, handsome presence is difficult to believe. His manner was abrupt and brusque, but the kindness of it was warmed with a sentimentality that he himself would have denied and of which he would almost have been ashamed had he known that we recognized it. His original contributions to surgery were important and he was astonishingly quick and dexterous as an operator; but it is by his teaching that he will be remembered. He was forceful, dogmatic, and even intolerant if the principles of Hugh Owen Thomas and Robert Jones were denied. It is difficult to measure the full extent to which he maintained and enhanced a great tradition. In Australia, Canada, and South Africa, as well as in this country, many young surgeons will remember a brilliant clinician, a great teacher, and a friend whose affections lay deep.

Mr. Bryan McFarland writes: It is difficult to believe that from what was to have been a visit to South Africa McMurray will never come back to Liverpool again. He seemed so young and vigorous a few days ago, still working and still taking his place in our councils and our celebrations. He was full of interest in his presidency of the B.M.A., and had already planned part of his presidential address, which incidentally would have left his listeners in no doubt about his opinion of merit awards. He was never inclined to "pull his punches." And he would disapprove most strongly if we were to allow our sorrow to interfere with the work which he has left us. Rather would he expect us with increased determination to devote ourselves to the threefold purpose which, up to the moment of his untimely death, had absorbed all his energies. To prevent and relieve crippling defects, to teach and to train orthopaedic surgeons, and to stimulate research constituted his whole *raison d'être*. The high tradition of skill, of experience, and of teaching handed on by Hugh Owen Thomas to Sir Robert Jones and in turn by him to McMurray was strikingly maintained. Through the Liverpool School there passed innumerable men who are now practising orthopaedic surgery in all parts of the world.

McMurray was essentially a good companion. Whether playing a game of golf (in which with hardly a glance at the ball he would sink ridiculously long putts), or playing cards (at which he invariably won), or throwing at coconuts in a fair, he was great fun. I never saw him happier than at a fair in Chester in 1940 when he smashed a whole stand of crockery for an outlay of half-a-crown. When he was doing nothing he did it just as thoroughly, and to see him sitting in the sun at Ystrad Cottage, gazing peacefully at the distant Denbighshire hills, the inevitable day-old newspaper on his knee, was an education in relaxation. He was a big man in the full sense of the expression. Just as there was nothing fiddling about his surgery and nothing mean in his dealings with men, so also there was nothing paltry in his reactions to the blows of fate. The death of his first wife caused neither a pause in his work nor an alteration in his manner, and only those who were very close to him knew how hard he was hit. We were overjoyed when his second marriage healed a wound to which he never admitted but of which we had begun to despair. He was very happy for the succeeding six years. Now we have lost one of our great men, and it will seem lonely in Liverpool without McMurray. But there is consolation in the knowledge that in all parts of the world there are men and women whose achievements will render immortal the personality and the work of Thomas Porter McMurray.

Mr. K. W. Monsarratt writes: Thirty years' friendship with McMurray has left chiefly in memory how completely and simply his vigorous activities were devoted to the work he chose for his own. He chose early, not long after he qualified, when good fortune brought him into association with Sir Robert Jones. This association was typical of all his loyalties; it was not only unbroken but never relaxed. It began with a house appointment at the Royal Southern Hospital; its last phase was when his name-plate was fixed on the door of 11, Nelson Street, Liverpool, under those of Sir Robert Jones and Hugh Owen Thomas. On the morning in May, 1941, the morning after 11, Nelson Street had been reduced to rubble by a bomb, he called at the Medical Institution. "I've lost my home," he said. About the beginning of the first world war he was appointed to a new department of orthopaedic surgery at the Northern Hospital, and he stayed on its active staff until he reached retiring age, two years ago. He was operating in the hospital the day before he died. He remained at home during the 1914–18 war, but what it cost him to stay at home only his intimate friends knew. The development of an organization for the treatment of the crippled soldier was in Robert Jones's hands, and McMurray was told he could not be spared to the Army. The first orthopaedic hospital in this country was established in Liverpool and he was put in charge. Seven or eight years after he had been appointed orthopaedic surgeon to the Northern Hospital he was pressed to join the staff of the Royal Infirmary. The Northern Hospital had been wise enough to give him the beds he wanted; his answer to the invitation from the senior hospital was characteristic. He said, "Thank you, I have what I want where I am." It was in the Northern Hospital that most of his adult orthopaedic work was done, but he had a full share in the development of this work among children, particularly in the Open Air Children's Hospital at Heswall, Cheshire, and in the Municipal Children's Hospital, Alder Hey.

In the University, recognition of orthopaedic surgery as a major specialty seemed to some unduly slow; it was represented by a lectureship only up to 1939, when a chair was established and McMurray became the first professor. His leadership among the younger men was worthy of the tradition of his chief, Robert Jones; perhaps he even exceeded his chief in the personal interest he took in those who passed through the school to work elsewhere. He was sparing of emotional expression, but his friends were not surprised by his grief at the loss in North Africa of his brilliant young disciple, Eastwood, in 1942. During the recent war he worked himself hard, as his many consultant appointments testify. Many young men will remember the courses of instruction in military orthopaedics

he organized and conducted, in place of the normal courses for the M.Ch.Orth., for whose high reputation he was principally responsible.

Those who were most closely associated with him wondered sometimes how little the ways to honours seemed to matter to him. Year in and year out it was the quality and perfection of the work he did, and saw done, that occupied him, but he was not too preoccupied to indulge freely in a sense of humour. He loved to "pull a leg." In 1941 a medical superintendent, much tried by a flood of air-raid casualties and not given to enthusiasms, said, "Professor McMurray's visits are an entertainment," then, after a moment, "and an inspiration." It may be said that the whole medical profession of Liverpool welcomed the opportunity of nominating him President of the British Medical Association. To him this meant that he would have a chance of helping to decide how the present changing conditions of medical practice might be directed to greater public benefit. He had already chosen this subject for his presidential address.

Professor G. R. Girdlestone writes: The sudden death of T. P. McMurray is a great loss to orthopaedics and a very sad blow to his friends and admirers all over the world. His achievements, distinctions, and eminence speak for themselves; but I would like to add a few words of personal appreciation, for I have known him intimately for thirty-five years, and we had many happy times together. His gifts of ability and temperament and his long association with Robert Jones enabled him to perceive by what procedure he could best help his patients; and to them he gave his unrivalled knowledge, experience, and skill with generosity and great kindness. He had an admirable confidence in his own judgment, but recognized in himself a certain capacity for nonconformity, so that when he brought out his excellent, if brief, textbook he was careful to call it *A* (not *The*) *Practice of Orthopaedic Surgery*. Unassuming, warm-hearted, and very friendly, his company was always delightful, with a wholesome appetizing flavour peculiarly his own. We mourn a great craftsman, and a great man, wise, direct, gay, and serene.

Dr. DALTON MALLAM died suddenly on October 23 at the age of 64. His early life was spent in the neighbourhood of Oxford, where his father was in practice. After qualifying at the London Hospital in 1913 he served as house-surgeon at Addenbrooke's Hospital, and it was there that he first practised his later well-known and very successful technique for tonsillectomy. He came to Redhill in 1919 and remained in general and surgical practice until 1947, when he retired owing to ill-health. During this time he was a member of the surgical staff for 25 years, and later consultant surgeon, at the East Surrey Hospital. He was always a sound, safe, and able general surgeon. During the 1914–18 war he served in France and the Middle East with the R.A.M.C. Dr. Mallam was associated with the development of the East Surrey mobile physiotherapy unit. He was chairman in 1939–41 of the Reigate Division of the B.M.A. In his spare time and holidays he loved birds, boats, and plants. He was a man of high principles, from which he never wavered; and this, combined with a meticulous attention to detail, a natural tidiness and punctuality of habit and mind, made him much valued as a trusted friend, a very able practitioner, and a colleague whom it was a pleasure to have known. To his widow and two sons the sympathy of all their friends will be extended.—W. W.

The Services

The Efficiency Decoration of the Territorial Army has been conferred upon Majors H. J. Heathcote, A. H. M. Richards, and J. T. Wybourn, Captain (Honorary Major) J. H. Whittles, and Captain T. R. W. Millar, R.A.M.C., T.A.

Colonel K. B. Fraser, R.A.A.M.C., has been appointed Honorary Surgeon to the King in succession to Brigadier (Honorary Major-General) R. W. W. Walsh, D.S.O., retired.

Medical Notes in Parliament

NATIONAL HEALTH SERVICE (AMENDMENT) BILL

The House of Lords on November 17 went into Committee on the National Health Service (Amendment) Bill.

Lord SHEPHERD, for the Government, accepted minor amendments to Clause 7 after the first six clauses of the Bill had been agreed without discussion. The first important Government amendment was a new clause to be inserted after Clause 14 as follows:

> Regulations made under Section 34 of the Act of 1946 and regulations made under Section 35 of the Act of 1947 may confer or impose on the Medical Practices Committee or, as the case may be, the Scottish Medical Practices Committee such additional functions in relation to arrangements for the provision of general medical services as may be prescribed.

Medical Practices Committee

Lord Shepherd said the purpose of the clause was to add to the authority of the Medical Practices Committee. The functions of that committee were, at present, technically limited to granting applications for inclusion in a medical list by doctors not yet on a medical list. The Government thought it important that the committee should have authority to look at all applicants for appointments. When a doctor on the list desired to appoint an assistant but the executive council for his area refused the appointment, the doctor should be able to appeal to the Medical Practices Committee, who could hear and determine the case. That was an illustration of the kind of extra authority which the new clause would give to the committee. The same powers would also be applied in Scotland by reference to the Act of 1947.

Lord LLEWELLIN said the new clause met a point made by the British Medical Association and had been agreed upon between that body and the Minister. He asked Lord Shepherd to see whether there ought not also to be consequential amendments to Sections 33 and 34 of the original Act. The advisers of the British Medical Association were not satisfied on that point. Section 33 expressly directed that regulations should be made requiring executive councils and not the Medical Practices Committee to arrange for the distribution of patients. Perhaps there ought to be some amendment to include the Medical Practices Committee in those regulations. Section 34 might require amendment in the same way, because as it stood it limited the functions which devolved on the Medical Practices Committee. He hoped Lord Shepherd and his advisers would look into these points before the report stage.

Lord SHEPHERD promised to respond to Lord Llewellin's suggestion, and the new clause was then agreed to.

Charge for Prescriptions

Lord Shepherd then moved to insert another new clause providing for the recovery of charges in respect of pharmaceutical services.

> Section 38 of the Act of 1946 and Section 40 of the Act of 1947 (which provide for the making of arrangements for pharmaceutical services) shall be amended by the addition at the end of each of those sections of the following subsection:
>
> (3) Regulations may provide for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such pharmaceutical services, as may be prescribed, and may provide for the remission or repayment of the charges in the case of such persons as may be prescribed.

Lord Shepherd said this clause gave the necessary statutory authority for the proposal already announced by the Prime Minister in the House of Commons to make a charge for prescriptions under the National Health Service. The clause was drafted in general terms because the exact nature of the arrangements to be made had not been settled. The Prime Minister had announced that the charge would in any case not exceed one shilling and that old-age pensioners would be relieved of it. The Minister of Pensions had explained that

war pensioners would continue to receive free treatment for their pensioned disabilities. No further particulars could be given at this stage.

The object of the amendment was twofold. It was to act as a deterrent to excessive or unnecessary resort to doctors and chemists and to reduce expenditure. Eventually it might be possible to tackle these problems on other lines. The Central and Scottish Health Services Councils had set up a Joint Committee to advise whether it was desirable and practicable to restrict or discourage the prescribing by doctors in the National Health Service of medicines of doubtful value or of unethical character, and of unnecessarily expensive brands of standard drugs. This Joint Committee consisted of members suggested by the Standing Medical and Pharmaceutical Advisory Committees of England and Wales, the Scottish Medical, Pharmaceutical, and General Practitioner Services Advisory Committees, the three Royal Colleges and the Scottish Corporations, the British Medical Association, the British Pharmacopoeia Commission, and the Society of Apothecaries. It was too early to say what might be found possible on those lines, but it was conceivable that in the long run the better way of handling the problem might be by general acceptance of a list of drugs of recognized value, with the corollary that a doctor would be expected to justify the prescribing of any not so recognized or unnecessarily expensive brands of recognized drugs. The clause would be applied to Scotland by the necessary reference to the Act of 1947. It was of a permissive character and would enable the Minister to vary conditions governing these practices.

Lord LLEWELLIN said he was glad that the Minister of Pensions had ensured that disabled ex-Servicemen would not have these charges placed upon them. That provision would give general satisfaction. He did not understand one sentence used by Lord Shepherd. He had not the faintest idea what an "unethical" medicine was. He noted that the new clause was a wide one. It gave general power to the Minister to make regulations to make charges. The House would have to watch what those regulations did when they came out. He did not know whether the principle of one shilling per prescription originally adopted by the Government would work in practice. He was told that 70% of the prescriptions which were made under the National Health Service were not handled by the pricing bureau. He was informed that a charge of one shilling for every prescription would require a much larger staff in the pricing bureau than there was at present, unless the intention was to make an average adjustment, as had apparently been done so far under the Health Acts. He asked whether the price was to be per prescription or per item on the prescription. A number of prescriptions given by doctors included more than one item. In addition to the provision for old-age pensioners and ex-Service people, some provision should be made so that people who had to take regularly a drug such as insulin did not have to obtain a fresh prescription each time and thereby have to pay for each issue of a drug which they must have.

Lord HAWKE asked when the financial effects of this scheme would be seen. Could Lord Shepherd give some forecast of when the charge would be imposed?

Lord SHEPHERD agreed that the time for discussion of many of these details would arrive when the regulations came before Parliament. This new clause merely gave the Minister power to prescribe regulations which would, he hoped, see the light of day before long. There would have to be consultations about them. Not only would the question of prescribing be reviewed by the Joint Committee, but there would also be consultation with the professional organizations about the details of the scheme for the recovery of charges. Many of the points which were causing disquiet in certain quarters would undoubtedly be considered by the Minister before the regulations were drafted.

He found it difficult to answer Lord Llewellin's inquiry. A suggestion had been given to him that "unethical treatment by the supply of drugs appears to be something that stimulates the emotions." As to the statement that 70% of the prescriptions were not handled by the pricing bureau, Lord Shepherd said that an attempt was being made to secure the system which under a fairly inexpensive administration would give the results which the Ministry required. The point Lord Llewellin had raised about the repetition of prescriptions for a given complaint would receive consideration. He might be able to give definite replies to Lord Hawke when the regulations were brought before Parliament. A certain amount of the financial effect would be in this year and the full fruits in a full year.

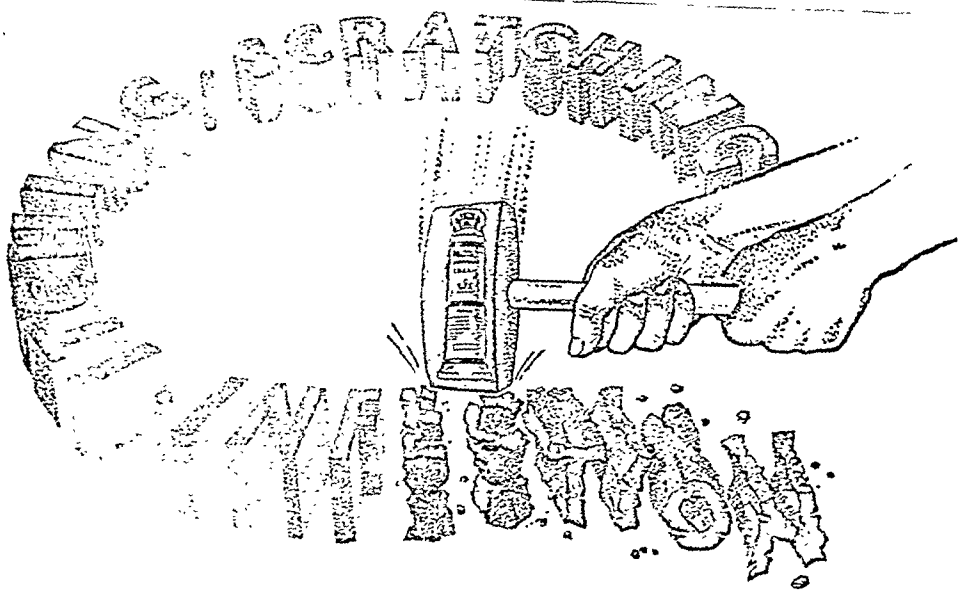
The proposed amendment was then agreed to.

Checking Abuse by Foreign Visitors

Lord Shepherd moved to insert another new clause on the recovery of charges from persons resident outside Great Britain.

.—(1) The powers of the Minister to make regulations under the Act of 1946 shall, notwithstanding anything in Section 1 of that Act, include power to make regulations providing for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such services provided under the Act of 1946, as may be prescribed, being services provided in respect of such persons not ordinarily resident in Great Britain as may be prescribed; and such regulations may provide that the charges are only to be made in such cases as may be determined in accordance with the regulations.

(2) This section shall apply to Scotland with the substitution for the reference to the Minister of a reference to the Secretary of State and for the reference to the Act of 1946 of a reference to the Act of 1947.



Lord Shepherd said the proposed clause gave power to make regulations for the making and recovery of charges for any use which might be made of the National Health Service by persons not ordinarily resident in this country. It was not the intention to exclude all foreign visitors from the benefits of the Health Service. Reasonable use of those services by those who fell ill when visiting this country was, in Mr. Bevan's view, a part of hospitality. Abuse by people who perhaps came to the United Kingdom mainly to take advantage of a free service was another matter. This clause was meant to give power to check abuse. Any regulations which might be made would not debar any person in this country from using the National Health Service but might require him to pay a charge for so doing. Subsection (1) of the new clause provided that the regulations made under the clause should specify to what services the charges would apply and what the charges were to be. The regulations would also lay down to what classes of persons not ordinarily resident in Great Britain the charges would apply. Owing to the difficulty in framing regulations which would not prove too rigid in their application to individual cases it was provided that the charges should be made only in cases where the Minister so determined.

Lord LLEWELLIN said the clause imposed on the Minister the responsibility for making regulations to recover from overseas visitors a charge for the use of health services. He recalled that Mr. Bevan, speaking in the House of Commons about an amendment on almost identical lines, had said that for him to accept such a responsibility was "absolutely and utterly impracticable." He was glad that on second thoughts the Minister had changed his opinion. He recalled that when the National Health Service (Amendment) Bill first came before the House of Lords he had remarked that it fulfilled promises three and a half years after suggestions on the same lines had been made in that House during discussions on the principal Act. He congratulated the Government that this time the suggestions of the House of Lords had been adopted within three and a half weeks.

The proposed new clause was agreed to.

On Clause 15, which concerns the superannuation of officers of certain hospitals, Lord Llewellin said that any hospital management, before availing itself of the facilities under the clause, would have to appreciate that as an employer it would place round its neck an unknown and unlimited liability in the matter of a deficiency contribution to the Minister's superannuation account. The same thing had happened under the Local Authority (Superannuation) Acts.

Lord SHEPHERD said he found that if there were an actuarial deficiency in the scheme of any particular hospital, the payments into the fund for that hospital might be increased. It would not be a question of making good a deficiency over the

POLYCREST

ANTIPRURITIC CREAM

A Causal and Symptomatic Therapy

THE "VICIOUS CIRCLE" OF PRURITUS

In the past in the treatment of pruritic conditions counter-irritants were employed which merely superimposed pain on itching.

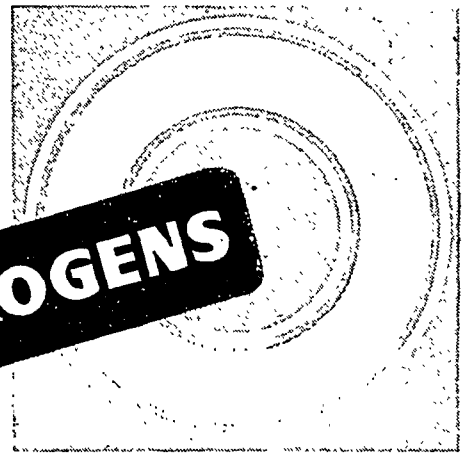
To-day it is realized that antipruritic therapy can only be effective if it is not only curative but also breaks the 'vicious circle' of itching — scratching — infection — more itching — and so on.

A CAUSAL AND SYMPTOMATIC THERAPY

This modern approach to the problem is embodied in Polycrest Antipruritic Cream, which combines the high bactericidal and fungicidal properties of Phenylmercuric Nitrate with the prompt and prolonged surface anaesthetic action of Amethocaine and Benzocaine, thereby affording simultaneous causal and symptomatic therapy.

INDICATIONS

Pruritus Ani, Haemorrhoids, Anal Eczema, Diabetic Pruritus and other pruritic conditions of diverse origins, including Epidermophytosis and other Tinea infections.



FORMULA

Phenylmercuric Nitrate	..	0.25%
Amethocaine	.. ..	0.50%
Benzocaine	.. ..	5.00%

INDIVIDUAL CORSETRY

When health demands surgical supports, the Strodex Service meets medical needs exactly. Every Strodex Corset and Belt is designed-to-measure and fitted by our qualified corsetieres to give effective support and personal comfort for such conditions as—Visceroptosis, Nephroptosis, Colostomy, Kyphosis, Sacro-iliac Strain and Hernia. Brassieres specially made for prolapsed breasts, maternity and nursing.

We illustrate a surgical abdominal support, or "Health Belt".

May we send you a copy of our booklet—"Surgical Supports"?

general body of hospitals. He promised to talk with Lord Llewellin about the point.

Clause 15, together with the remaining clauses and schedule, were then agreed to and the committee stage concluded.

Dispensing Doctors

Mr. SKINNARD on November 17 asked what proportion of medicines prescribed under the National Health Service was dispensed by doctors; and how payment for the drugs was made in such cases.

Mr. BEVAN said no precise information was available, but the estimated proportion supplied by doctors under Part IV of the National Health Service Act was one-tenth. Doctors giving general medical services and maternity medical services supplied medicine to their patients in the following circumstances, and it was paid for in the following ways.

1. Prescribing doctors were required to supply drugs and appliances needed for immediate administration or before a supply could be obtained from a chemist. For this they received payment at the rate of 2s. 6d. per hundred patients on their list, with additional payment for expensive drugs in a Special List.

2. Prescribing doctors might themselves supply any drug normally administered by a doctor in person—e.g., an injection. For this they were paid the value of the drug plus a fee.

3. In country districts where no chemist was readily available, doctors might be required to supply all drugs and appliances needed for the treatment of their patients. For this they might be paid in two ways: (*a*) at the rate of 6s. 6d. per dispensing patient with additional payment for expensive drugs in a Special List, or (*b*) on the basis of the Drug Tariff for all drugs and appliances actually supplied.

Cost of Prescription

Dr. BROUGHTON asked on November 17 what was the average cost of National Health Service prescriptions; how much of that amount was dispensing fee; and how much the cost of container.

Mr. BEVAN in reply said the average cost of National Health Service prescriptions in England and Wales was at present about 3s. Of that amount one shilling and one-third of a penny represented the average dispensing fee and a penny farthing the average cost of containers. He had no changes in mind in these forms of expenditure.

Mr. PIRATIN asked Mr. Bevan, before introducing his regulation on payment for prescriptions, to consider reducing the average price of prescriptions, even if this involved lowering the profits of certain firms.

Mr. BEVAN replied that these matters had been looked into and the profits of the firms had already been reduced.

Diphtheria.—Local authority returns show that in England and Wales 2,431 children under the age of 15 were reported as suffering from diphtheria in 1948, and that 783 of them had been immunized. Of 126 children who died from diphtheria only six were immunized.

Hearing Aids.—Asked what assistance he gave to deaf persons to whom the Medresco deaf-aid was of no use but who could hear with the aid of other appliances, Mr. BEVAN replied on November 1 that non-electrical aids were provided in suitable cases. Steps were being taken to develop a new Medresco aid for the small minority who needed it.

Invalided Out.—The average yearly number of men who have been invalided out from the Army since August, 1945, is 32,616. This figure excludes 9,518 men who were invalided out as a result of wounds between August, 1945, and December, 1946.

Items Prescribed.—Mr. SKINNARD on November 17 inquired what percentage of the prescription forms dealt with by the pharmaceutical pricing bureaux carried a single prescription, and what percentage more than two. Mr. BEVAN said that precise data were not available. Evidence before him suggested that the average percentages were about 60% and a little under 10%, respectively.

Professor Crighton Bramwell, professor of cardiology in the University of Manchester, has recently gone to Italy for a lecture tour sponsored by the British Council. He is lecturing in Turin, Milan, Padua, Bologna, and Rome on "The Normal Heart," "Heart Disease and Pregnancy," "Phonocardiography," and "Subacute Bacterial Endocarditis."

UNIVERSITY OF MANCHESTER

The Council has appointed Sir John Stopford, F.R.S., as representative of the University on the Court of Governors of the University College of North Staffordshire.

The Council has decided to apply the gift of £1,699 made by the parents of children who during the 1939–45 war were evacuated to Canada in the establishment of a fund to make grants to Canadians wishing to conduct postgraduate studies and/or research in the University, a preference being given to students who shall have graduated in the University of Toronto.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 5. [No. 44

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Rate per 1,000 total births (including stillborn)			31					25		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

Notifications in England and Wales in the week ended November 12 were: poliomyelitis 293 (318), polio-encephalitis 23 (12). Figures for the previous week are in parentheses. Thus the slow decline in incidence continues.

Multiple cases were reported from the following counties. London 50 (55), Bedford 6 (2), Berkshire 7 (3), Buckingham 2 (4), Chester 16 (10), Derby 3 (2), Devon 3 (3), Dorset 7 (3), Durham 3 (2), Essex 24 (26), Gloucester 6 (9), Hereford 4 (2), Hertford 4 (9), Huntingdon 5 (0), Kent 15 (16), Lancaster 26 (32), Leicester 12 (3), Lincs, Lindsey 5 (13), Middlesex 14 (17), Norfolk 7 (5), Northampton 4 (1), Northumberland 4 (2), Nottingham 9 (8), Oxford 2 (2), Salop 2 (0), Somerset 2 (11), Southampton 9 (13), Stafford 7 (3), East Suffolk 2 (2), Surrey 6 (14), East Sussex 5 (9), West Sussex 1 (3), Warwick 7 (8), Westmorland 3 (1), Wiltshire 2 (1), North Yorks 2 (2), West Yorks 36 (50), Glamorgan 4 (7).

Discussion of Table

In *England and Wales* increases were recorded in the notifications of whooping-cough 149, acute pneumonia 116, measles 87, and scarlet fever 76, while decreases were reported for dysentery 56 and diphtheria 15.

The incidence of scarlet fever is about three times the level of 10 weeks ago, and the notifications give the largest weekly total for almost two years. This rise in the incidence of scarlet fever during the week was contributed by the northern section of the country; in the southern section a small decrease was reported. The largest of the local increases in notifications was Cheshire 44.

The chief feature of the returns for diphtheria was a decrease of 6 in the number of notifications in Staffordshire and in Lancashire. In only a few counties was any variation recorded in the trend of measles. The only increase of any size in the incidence of measles was Durham 81, due to a rise from 16 to 70 in South Shields C.B.; the largest decreases were Kent 31 and London 30.

The largest variations in the incidence of whooping-cough were a decrease of 26 in Lancashire and a rise of 32 in Durham, mainly due to Hetton U.D., where the notifications rose from 3 to 21.

The only large return for dysentery was 43 notifications in Lancashire (Liverpool C.B. 17, Ince in Makerfield U.D. 10).

In *Scotland* increases were recorded in the notifications of acute primary pneumonia 46, scarlet fever 45, dysentery 15, and cerebrospinal fever 13. The largest rise in the notifications of scarlet fever was 20 in Zetland county. An increase of 7 in the notifications of dysentery was recorded in both Edinburgh and Glasgow.

In *Eire* there was an increase of 63 in the notifications of scarlet fever with a decrease of 49 for measles. A rise in the incidence of scarlet fever occurred throughout the country; the largest increase was 31 in Dublin C.B. A fall of 68 in the notifications of measles was recorded in Waterford C.B. An increase of 14 in the notifications of diarrhoea and enteritis was reported from Dublin C.B.

In *Northern Ireland* there were increases in the notifications of measles 23 and scarlet fever 15. These rises were mainly due to the experience of Belfast C.B.

Week Ending November 12

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,163, whooping-cough 977, diphtheria 85, measles 1,055, acute pneumonia 534, cerebrospinal fever 20, acute poliomyelitis 293, acute polio-encephalitis 12, dysentery 92, paratyphoid fever 7, typhoid fever 18, food-poisoning 50.

Medical News

General Medical Council

Professor David Campbell, Regius Professor of Materia Medica in the University of Aberdeen, was elected President of the General Medical Council on November 22 in succession to the late Sir Herbert Lightfoot Eason.

New Dean Appointed

Professor Andrew Topping has been appointed whole-time Dean of the London School of Hygiene and Tropical Medicine. He will take up his duties in the middle of February, 1950. Professor Topping graduated M.B., Ch.B. at the University of Aberdeen in 1914, and served with the R.A.M.C. in Gallipoli and Mesopotamia during the first world war. For some years he was senior medical officer at Abadan in Persia and, on his return to England, became medical officer of health of Rochdale. After serving in the London Fever Hospital service he became deputy medical officer of health to the London County Council and lecturer in public health at Charing Cross Hospital Medical School. During the second world war he was deputy chief of the Relief Services of Unrra and subsequently director of health of the European division. He is at present Professor of Social and Preventive Medicine in Manchester University. As previously reported, Professor J. M. Mackintosh has resigned from the position of Dean, but will continue to teach in the school as Professor of Public Health.

Queen's Gift to Royal College

The Queen has given £1,000 to the Royal College of Obstetricians and Gynaecologists. This was announced by Sir William Gilliatt on November 22, speaking at a luncheon at the College's House to launch an appeal for £400,000. Of the sum required, £350,000 was for research, building, and general funds, and £50,000 for a travelling professorship.

B.C.G. Vaccination in London

The Health Committee of the London County Council is proposing that the Council shall participate in the local health authorities' arrangements for the prevention of tuberculosis under Sect. 28 of the National Health Service Act by providing for B.C.G. vaccination. The vaccination, in the terms of the proposal to be submitted to the Minister, will be provided "by, and at the instance of, physicians with specialist knowledge and experience of tuberculosis, as regards persons to whom it is judged medically expedient, subject to the necessary preliminary tests, to afford such vaccination in view of their known contact with tuberculous infection or selected groups of the population, as agreed by the Ministry of Health." It is considered advisable that all contacts, both children and adults, of tuberculous patients in London should be considered for vaccination. All the chest physicians in charge of the chest clinics in London will be nominated for the purpose. The person to be vaccinated may have to be segregated from known sources of infection while tuberculin testing and vaccination are being carried out, up to a total period of 12 weeks, or more if the vaccination is not at first successful. The Council itself may have to provide for the segregation of at least 150 children and, in special circumstances, a small number of adults at any time during the year. Copies of the proposal have to be served on every voluntary organization which, to the knowledge of the Council, provides services of the kind dealt with in the proposal, on the London Executive Council, the four metropolitan regional hospital boards, and the boards of governors of each teaching hospital in the county, and on every local authority within the administrative area. It is not proposed that the arrangements for B.C.G. vaccination of persons other than hospital staffs and medical students shall be brought into operation until after April 1, 1950.

Sheriffs

Dr. D. R. Lewis, of Swansea, has been nominated a sheriff for Breconshire and Dr. R. Davies Jones, of Llanidloes, a sheriff for Montgomeryshire for 1949.

Sickness Benefit Regulations

Under the National Insurance scheme increases of unemployment and sickness benefit may be paid to beneficiaries with dependants who fulfil certain conditions. The National Insurance Advisory Committee has been asked to consider and report on the preliminary draft of regulations which extend to one month from the date of entitlement the maximum time for claiming an increase of unemployment or sickness benefit for a dependant. The regulations also provide for extending the period of one month in cases in which good cause for delay in claiming is shown. Copies of the preliminary draft of these regulations (the National Insurance (Claims and Payments) Amendment (No. 3) Regulations, 1949) can be bought for 1d. from H.M. Stationery Office or any bookseller. The committee will consider written objections to them if sent before December 16 to the secretary, National Insurance Advisory Committee, 6, Curzon Street, London, W.1.

Analgesia Administered by Midwives

The total number of administrations of analgesia by midwives in the domiciliary midwifery service of London during the first six months of the present year was 5,204, being 61% of all the confinements taken by midwives. The figure for the previous six months was 3,611, or 42% of all confinements. The number has risen considerably each half-year since analgesia was introduced for their use in 1946. The figures given exclude maternity nursing cases in which analgesia or anaesthesia was given by doctors. Of the L.C.C. midwives, all but one of the 149 in the service are qualified to administer analgesia, and of the midwives employed by the district nursing associations and by hospitals on district work 88 out of a total of 93.

Institute of Medical Laboratory Technology

At the annual general meeting of the Institute held in Oxford on July 29 the following exemptions from Institute examinations were approved. Exemption from the final examination for associateship may be granted to those in possession of a science degree (or an A.R.I.C.—Associateship of the Royal Institute of Chemistry), in approved subjects with not less than one year's experience in approved pathological laboratories, on payment of the appropriate fee. These associates may qualify for fellowship by thesis after a further three years' experience. Exemption from the intermediate examination may be granted to those having not less than 15 years' experience in approved pathological laboratories prior to July 29, 1949, on payment of the appropriate fee. Copies of the Institute's memorandum and articles of association may be obtained from 76, Brewer Street, W.1. Price 1s., plus 2½d. postage.

William Hyde Award

The Research Board for the Correlation of Medical Science and Physical Education has awarded the William Hyde Award of £300 for 1948 to Dr. J. M. Tanner, of the Sherrington School of Physiology, St. Thomas's Hospital, in recognition of his work on somatotypes in medicine and his papers on the relation between physique and physical function. He states that he will use part of the gift for a monograph on "The Physique of the Human" which he is now writing. The award is made from funds provided by the Nuffield Trust in memory of William Hyde, who died in 1945, and whose concern for the future of the hospital services of the country to a large extent led to the establishment of the Nuffield Provincial Hospitals Trust.

Hospital Directory

The Ministry of Health has prepared a directory giving information about the hospitals and their boards and management committees in England and Wales. Addresses and telephone numbers are given, and the number of beds at the hospitals. Entitled "Hospitals Directory, England and Wales," it is obtainable from H.M. Stationery Office for 3s.

Wills

Sir Thomas Crisp English, who was for many years surgeon to St. George's Hospital, left £31,061. Dr. Henry Anstey Cookson, of Sunderland, left £21,266; and Dr. Frank Butterfield, of Blackburn, £7,745.

COMING EVENTS

Scientific Films

The Society for Cultural Relations with the U.S.S.R. has arranged to show two films in connexion with the Pavlov Centenary celebrations. The first, "Mechanism of the Brain," will be shown on Monday, November 28, at 5 p.m. at the Anatomy Theatre, Guy's Hospital Medical School, London, S.E.1, and the second, "Academician Pavlov," at the Hammer Theatre, Wardour Street, London, W.1. Admission to the first film will be by series ticket already issued, or by ticket (2s. 6d.) on application to the society at 14, Kensington Square, London, W.8. Admission to the second will be by series ticket or by the "Pavlov" issue of the *Anglo-Soviet Journal* (2s. 6d. from the society).

Osler Club

The next meeting of the club will be at the Medical Society of London, 11, Chandos Street, W.1, at 8 p.m., on Thursday, December 1. Professor J. Z. Young will speak on Pavlov and the work following his pioneering research, and Mr. R. Scott Stevenson will speak on Sir Felix Semon and his work in laryngology.

Bolton Royal Infirmary

Mr. Harold Balme, Medical Officer in Charge of Rehabilitation, Ministry of Health, will open the extensions to the Department of Physical Medicine and Rehabilitation at the Bolton Royal Infirmary on Thursday, December 1, at 3.15 p.m.

The Victor Horsley Memorial Lecture

The Victor Horsley Memorial Fund, which was raised in 1920 to commemorate the services of Sir Victor Horsley to science and the Empire, is devoted to the giving of a lecture triennially in London entitled the "Victor Horsley Memorial Lecture." By invitation of the trustees (the Presidents for the time being of the Royal Society, the Royal College of Surgeons of England, and the British Medical Association, the Senior Physician of the National Hospital, Queen Square, and Mr. Stanley G. Robinson, son-in-law of Sir Victor Horsley) the eighth lecture will be delivered by Sir Hugh Cairns, Nuffield Professor of Surgery, University of Oxford, in No. 1 Lecture Room, University College Hospital Medical School, University Street, Gower Street, London, W.C.1, on Thursday, December 8, at 5 p.m. The title of the lecture is "Disturbances of Consciousness with Disorders of the Brain Stem," and the chair will be taken by Dr. F. M. R. Walshe, F.R.S. Admission to the lecture is free on presentation of visiting-card.

SOCIETIES AND LECTURES

Monday

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W.—November 28, 8.30 p.m., Discussion: "*Impotence*," to be introduced by Drs. S. L. Simpson and E. B. Strauss.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C. November 28, 6 p.m., "*Bread*," Cantor Lecture, by Mr. D. W. Kent-Jones, Ph.D.

UNIVERSITY COLLEGE, Gower Street, London, W.C.—November 28, 4.45 p.m., "*Bacterial Toxins*," by Dr. W. E. Van Heyningen.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—November 29, 5 p.m., "*Lupus Erythematosus*," by Dr. W. N. Goldsmith.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—November 29, 3.45 p.m., "*The Virus Theory of Cancer in the Light of Recent Work*." Imperial Cancer Research Fund Lecture by Dr. C. H. Andrewes, F.R.S.

Wednesday

BRITISH PSYCHO-ANALYTICAL SOCIETY.—At Royal Society of Medicine (Barnes Hall), 1, Wimpole Street, London, W., November 30, 8 p.m., "*Poetical Truth and Scientific Truth in the Light of History*," by Professor Arnold Toynbee.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—November 30, 3.30 p.m., "*The Need for Smoke Abatement*," by Sir George S. Elliston.

SOCIAL PSYCHOTHERAPY CENTRE, 7, Fellows Road, London, N.W.—November 30, 5 p.m., "*Shorter Methods of Child Guidance*," by Miss J. Balls and Mrs. S. Kras.

Thursday

HONYMAN GILLESPIE LECTURE.—At Anatomy Theatre, University New Buildings, Teviot Place, Edinburgh, December 1, 5 p.m., "*Observations on Cirrhosis of the Liver*," by Dr. D. M. F. Batty.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—December 1, 5 p.m., "*Ulceration of the Mouth*," by Dr. L. Forman.

INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill, London, S.E.—December 1, 4.30 p.m., "*The Visual System*," by Professor W. E. Le Gros Clark, F.R.S.

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., December 1, 5.30 p.m., "*Some Problems of Old Age*," by Dr. J. H. Sheldon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—December 1, 5 p.m., "*Intracranial Abscess*," Otolaryngology Lecture by Professor Geoffrey Jefferson.

ROYAL PHOTOGRAPHIC SOCIETY: MEDICAL GROUP.—At 16, Princes Gate, London, S.W., December 1, 7 p.m., "*Criticism of Lantern Slides from a Medical Point of View*," Surgeon critic, Mr. Hedley J. B. Atkins; Medical critic, Professor G. W. Pickering.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—December 1, 4.30 p.m., lecture-demonstration: "*Neurology*," by Dr. A. Feiling.

Friday

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, London, S.E.—December 2, 4.30 p.m., Legg Memorial Lecture by Mr. Geoffrey Keynes

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES MEDICAL SCHOOL, Maida Vale, London, W.—December 2, 5 p.m., clinical demonstration by Dr. H. E. Dimsdale.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—December 2, 8 p.m., "*Disseminated Sclerosis*," by Mr. J. J. MacCabe.

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY, Whipps Cross Hospital, London, E.—December 2, 8.30 p.m., "*Recent Advances in Therapy of Mental Diseases*," by Dr. T. P. Riordan.

Saturday

KENT PAEDIATRIC SOCIETY.—At Children's Hospital, Woodland Way, West Wickham, December 3.

YORK MEDICAL SOCIETY.—At 17, Stonegate, York, December 3, 8.30 p.m., "*Deformities of the Jaw*," by Professor M. A. Rushton.

APPOINTMENTS

BROWN, GEORGE GORDON, L.R.C.P. & S. Ed., L.D.S., D.P.M., Medical Superintendent, St. Mary's Mental Defective Institution, Newport, Isle of Wight.

CHARLTON, E. P. H., M.D., D.P.M., Consultant Psychiatrist and Deputy Physician Superintendent, Graylingwell Hospital, Chichester, Sussex.

MAYES, JOYCE B. M., M.B., B.S., D.P.H., Medical Officer of Health, Blandford Borough, Blandford Rural District, Wimborne Urban District, and Wimborne-Camborne Rural District, and Assistant County Medical Officer of Health and Assistant County School Medical Officer, Dorset County Council.

WILLIAMS, T. M., B.M., B.Ch., F.R.C.S., Consultant General Surgeon at West Suffolk General Hospital, Bury St. Edmunds, East Anglian Regional Hospital Board.

WILSON, WILLIAM D., M.D., D.P.H., Medical Officer of Health, Burgh and County of Inverness.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Russell.—On November 14, 1949, at 9, Baring Crescent, Exeter, to Stephanie, wife of P. M. G. Russell, F.R.C.S., M.R.C.O.G., a daughter—Susan Gordon.

Tweedie.—On October 25, 1949, to Isobel (née Cochrane, M.B., B.Ch.), wife of W. M. Tweedie, 56, Richmond Hill, Richmond, Surrey, a son.

Welch.—On November 18, 1949, at Elvet House, Dean Road, South Shields, to Dr. and Mrs. H. D. Welch, a son.

DEATHS

Blank.—On November 16, 1949, at 38, Mapesbury Court, Shoot-up-Hill, London, N.W., Dagobert Blank, M.D., aged 69.

Braithwaite.—On November 10, 1949, at Whitehaven, Henry Mounsey Braithwaite, M.D., Surgeon Captain R.N., Ret., aged 67.

Evison.—On November 13, 1949, at Brook Lodge, Huxley, near Chester, Hanson Cotton Evison, M.B., C.M.

Felce.—On November 14, 1949, at The Cedars, Lingfield, Surrey, Stamford Grant Felce, M.D., aged 83.

Finlayson.—On November 18, 1949, at Edinburgh, William Thomas Finlayson, O.B.E., L.D.S., L.R.C.P.&S.Ed., Lieutenant-Colonel, R.A.D.C.

Hall.—On November 14, 1949, William Scott Hall, M.B., Ch.B., late of Scunthorpe, Lincs.

Husband-Clutton.—On November 19, 1949, at Crowland, Peterborough, Frank Husband-Clutton, M.R.C.S., L.R.C.P., J.P., aged 78.

Mackay.—On September 27, 1949, at Edmonton, Alberta, Canada, Joseph Bogue Mackay, M.B., Ch.B., aged 64.

McMurray.—On November 16, 1949, suddenly, in London, Thomas Porter McMurray C.B.E., F.R.C.S., Emeritus Professor of Orthopaedic Surgery, University of Liverpool; President-Elect, British Medical Association, aged 61.

Price.—On November 18, 1949, at St. Bartholomew's Hospital, London, E.C., David Cromwell Price, F.R.C.S.

Thomson.—On November 16, 1949, at the home of his niece, Andrew George Anderson Thomson, M.B., C.M., of Bridport and Bournemouth.

Weaver.—On November 15, 1949, after a short illness, Alfred Ernest Remmett Weaver, M.D., D.P.H., of 55, Beach Road, Weston-super-Mare.

Virol

A GREAT BUILDING-UP FOOD FOR CHILDREN AND INVALIDS

VIROL is a concentrated food of high nutritional value, and provides just those factors most likely to be needed to complete the diet.

THE INGREDIENTS of Virol are : malt extract, refined beef fat, maltose, sugar, malto-dextrins, glucose, fructose, egg, orange juice, salt, flavourings, phosphoric acid, calcium phosphate, iron phosphate, sodium iodide, and added vitamins.

VIROL CONTAINS per ounce : Vitamin A, 500 i.u., Vitamin D, 1,000 i.u., Vitamin B_1 (Aneurin), 0.2 mg., Nicotinic Acid, 3.0 mg., Iron, 8 mg., Iodine, 75 Micro-g., together with unstandardised amounts of other essential nutrients.

The addition of Virol to ordinary cows' milk for infant feeding is a valuable means of supplying those minerals and vitamins which are deficient—except Vitamin C, which is readily obtained from orange or other fruit juice. Virol is also an invaluable supplementary food for growing children. During illness and convalescence, when it is necessary to maintain the patient's strength without undue strain on the digestion, VIROL—because it is so palatable and easily absorbed—has proved to be a most nutritious restorative.

Virol completes the diet

VIROL LIMITED, LONDON, W.5.

For Control in Parkinsonian States

PARPANIT

Trade Mark Brand

l-phenyl-cyclopentane-l-carboxylic acid diethylaminoethylester hydrochloride

PARPANIT is a new substance for the treatment of conditions characterised by muscular rigidity and tremor, particularly Postencephalitic Parkinsonism and Paralysis agitans; it has been the subject of many clinical trials, including that reported in *The Lancet*, 1948, 2, 724. The action of Parpanit is not limited to the relief of symptoms of disorders of the extrapyramidal system and a trial is justified in all affections accompanied by an increase of muscle tone.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Alcohol after Infective Hepatitis

Q.—*For how long after an attack of "jaundice" should a patient keep off alcohol? What form of alcohol might he start off with?*

A.—It is difficult to lay down any hard-and-fast rule about the period for which a patient who has had infective hepatitis—it is assumed that this was the cause of the jaundice in question—should abstain from alcohol. There is no experimental evidence that alcohol has any direct toxic action on the liver, and the paper by Best and his colleagues in a recent number of the *Journal* (November 5, p. 1001) shows how improbable such an effect is. Nevertheless, a relapse of hepatitis has followed the taking of alcohol shortly after the primary attack, and it is well known that the tolerance for alcohol of patients who have had hepatitis is often diminished for weeks or even months afterwards. Headache, anorexia, flatulence, and abdominal discomfort may be the result of taking even one or two drinks, particularly after severe attacks. For these reasons most physicians advise their patients not to drink for a time after infective hepatitis. The period stipulated varies with the individual physician, and experience alone can decide what it should be. The writer always suggests six weeks without alcohol after a mild attack, but if the attack has been more severe than the average, and particularly if there has been a relapse, the time is increased to three months. It must be admitted that there are only empirical grounds for this recommendation. Experience suggests also that extreme moderation is advisable when alcohol is taken, and that indulging in heavy wines and taking drinks before meals are unwise.

Intranasal Oil and Cancer of Lung

Q.—*Preparations of vasoconstrictors in oil are increasingly used intranasally in the treatment of a number of conditions. Is there any evidence that the use of mineral oils for this purpose is a factor in the increased incidence of pulmonary carcinoma?*

A.—There is certainly no evidence that the administration of vasoconstrictors in oil is a factor in the increased incidence of pulmonary carcinoma, although any further answer to the query is necessarily limited by absence of information on the oils themselves (and particularly whether they are in fact carcinogenic), and by lack of data concerning the extent to which these medicaments are employed and for how long. The only possible way of arriving at an answer to the question is by consideration of the intrinsic carcinogenic effects of the oils concerned. Although it is known that in certain circumstances some of the oil introduced into the nose in this way will reach the lungs, the duration of its contact with the bronchi is very brief, and, if it is not removed by the normal defences, it comes to rest in the terminal part of the broncho-pulmonary tree, far from the site of origin of the vast majority of bronchial carcinomata. Also, if these oils are carcinogenic, one would expect the effect to be much more noticeable in the case of malignant disease within the nose itself; so far as is known there is no evidence that the incidence of this is increasing. These considerations aside, it is improbable that we have here a likely factor. On the general problem the query assumes the recorded increase of pulmonary cancer to be real—a conclusion which is increasingly accepted and almost certainly correct. While any new facts or even hints as to causation must always be welcome, the prevailing tendency is to regard the increased consumption of cigarettes which has occurred in most communities over the past 30 years as a major factor, though there is so far no conclusive statistical evidence of cause and effect.

Proguanil as a Malaria Suppressant

Q.—*What is the efficiency of proguanil as a malaria suppressant? What incidence of clinical attacks of all types of malaria might one expect on leaving an endemic area if suppressive administration of proguanil (0.1 g. daily) is continued for a period of seven to 10 days? Can any other measures be taken to ensure that clinical attacks are reduced to the absolute minimum?*

A.—Proguanil is a relatively efficient and non-toxic malaria suppressant, although certain African strains of *Plasmodium falciparum*, when compared with Pacific strains of the organism, appear somewhat resistant to the drug, and instances where the drug has failed against such resistant strains have been recorded. Few attacks of falciparum malaria should be expected after leaving an endemic area if suppressive proguanil 0.1 g. daily is continued for 10 days, but vivax malaria may of course relapse despite such treatment. The frequency of relapses of vivax malaria may be reduced by taking one of the 8-aminoquinoline drugs—for example, pamaquin, 0.01 g. thrice daily for 10 to 14 days; with each dose of the drug it may be more effective to combine quinine 0.6 g. or mepacrine 0.1 g.

Osgood-Schlatter Disease

Q.—*What is the latest treatment for Osgood-Schlatter disease?*

A.—There have been no recent developments in the treatment of Osgood-Schlatter disease of the epiphysis of the tibial tubercle. Although the exact cause is still unknown, the condition is thought to be a form of osteochondritis; the underlying cause may be some disturbance of the blood supply of the epiphysis. The treatment depends on the severity of the symptoms. When pain and local tenderness are severe the best treatment is to immobilize the limb for eight to 12 weeks in a plaster cylinder. After this the symptoms as a rule are no longer troublesome, and the disease gradually becomes resolved in the ensuing months. When the initial symptoms are slight, plaster may be dispensed with without risk to the knee.

Idiopathic Epilepsy

Q.—*What investigations are called for in the case of a man who at the age of 34 has for the first time an attack of sudden unconsciousness with marked cyanosis and convulsions? On examination later there appeared to be no obvious neurological abnormality. What are the possibilities?*

A.—It is unusual for idiopathic epilepsy to manifest itself first at the age of 34, but this is a possibility. If the patient has resided in the Tropics cysticercosis would need to be considered. Although recently published figures show that intracranial tumour is the cause of epilepsy beginning in adult life in only about 12% of cases, nevertheless steps must be taken to exclude it. Syphilis also requires to be thought of, and inquiries should be made about any history of head injury. This list includes all the most probable causes. Investigations must begin with a complete clinical examination of the patient, especially of the ocular fundi and the nervous and cardiovascular systems. An electroencephalogram should be obtained. It may prove normal, but modern methods yield a positive result in a high proportion of cases even in adult life—a diffuse dysrhythmia would suggest idiopathic epilepsy, and a focal dysrhythmia, either of irregular spikes or of delta rhythms, would support a focal cause. A blood Wassermann test and a complete examination of the cerebrospinal fluid should be carried out. These procedures would serve to exclude syphilis, while a raised protein level as the only abnormality in the cerebrospinal fluid would favour a diagnosis of tumour. A complete radiological examination of the skull should be made, and of the soft tissues around the shoulders and hips for the presence of cysticerci. In some cases it may be necessary to carry out air encephalography and cerebral angiography.

Treatment of Asthma

Q.—*A patient claims that she was cured of asthma by taking large doses of a preparation containing theophylline on going to bed. Is this result possible, and what dosage is called for in a young adult?*

A.—Theophylline is an effective bronchodilator, and is often used in the symptomatic treatment of asthma. It is most effective when injected intravenously, but can be given in tablet form. When taken by mouth it is a gastric irritant. The usual dose by mouth is 0.2 g., or intravenously 0.25 g. It may control the symptoms of mild asthma, but is no more likely to lead to cure than is adrenaline, stramonium, or any other symptomatic remedy.

Distension of Gut

Q.—*(a) How does obstruction of the lower bowel cause ballooning of the rectum? (b) How does uraemia cause distension of the bowel? (c) How does strangulated omentum cause constipation?*

A.—*(a)* The rectum derives its nerve supply from (i) sympathetic fibres following the superior haemorrhoidal artery and derived from branches of the pelvic sympathetic plexus accompanying radicles of the middle haemorrhoidal artery, and (ii) the pelvic splanchnic nerves derived from the third and fourth sacral roots (sometimes also the second) with communicating branches from the second and third lumbar roots. Obstruction of the lower bowel, either by distension or by direct involvement of the wall, paralyses the sympathetic fibres in the coats of the bowel, the nerves being motor to the circular muscle. At the same time the spinal nerves, which are not usually involved until a late stage, are unopposed in their inhibiting action on the circular muscle. Both effects lead to passive ballooning below the obstruction—this being most marked in growths of the lower sigmoid colon and pelvi-rectal junction.

(*b*) Although of recent years a great deal more has been discovered concerning uraemia, the actual by-products of inefficient filtering by the kidney are unknown; but it is a reasonable assumption that one or more of these are toxic substances which when circulating in the blood stream lead to irritation of the intestinal mucosa. The entero-colitis of the terminal stages of uraemia is a well-known entity. The inflammatory reaction causes a pouring out of fluid into the gut, thus accounting for a certain part of the distension. The fact that this fluid contains large numbers of gas-forming organisms accounts for yet further distension, and it is possible also that a circulating toxin may have an inhibitory effect on the sympathetic nerve supply of the gut and so lead to paresis.

(*c*) If strangulation is taken to imply vascular obstruction, then it is unlikely that the patient will remain long enough without surgical treatment for constipation to develop.

High-pitched Voice in Adult Male

Q.—*What are the commonest causes of a high-pitched voice in an adult male? Is it possible for the speaking voice of a man so affected to be lowered—that is, to be made more masculine? If so, what is the treatment?*

A.—Physiologically the voice breaks at puberty, and this is due to the increased secretion of androgens, which stimulate enlargement of the larynx. If puberty is late, the break in the voice is correspondingly delayed. In eunuchoids the break may be delayed until the third or fourth decade, or may never occur. In women who develop virilism due to an adrenal tumour or adrenal hyperplasia there is an increased secretion of androgens with deepening of the voice. This may also occur when testosterone is given to a woman for various reasons—for example, in the treatment of menorrhagia or carcinoma of the breast.

The above clinical considerations indicate that testosterone may be effective in lowering the man's speaking voice if there is other evidence of androgen deficiency. However, there are cases in which the patient is otherwise completely normal, and we must postulate an abnormality in the construction of the larynx or an absence of sensitivity to the testosterone stimulus. In these circumstances no benefit would result from such therapy.

Specificity of Spa Treatment

Q.—*Is it true that the medical profession generally during the last few years has indicated that it does not believe that there is any specific medicinal value in any mineral or spa waters?*

A.—If the literature on rheumatic affections and other types of disease which are generally regarded as being suitable for spa treatment is examined the impression emerges that the physicians who practise in spas in this country no longer believe much in the *specific* attributes of their waters. The tendency nowadays is towards explaining the undoubted benefits of spa treatment on the basis of the physical methods employed. Medical hydrology ranks as an important branch of physical medicine; balneology has become rather "old-fashioned," except in one or two countries on the continent of Europe.

Stainless Steel Dentures

Q.—*What complications may follow the use of dentures with a stainless steel face, as compared with plastic dentures? Which type would normally be preferred?*

A.—Good stainless steel is an excellent material for use as a denture base, having the advantages that it is non-staining, clean, and heat-conducting. It has, however, the great disadvantages that it cannot readily be cast, so that it cannot be employed for skeleton dentures as can gold alloys; if it is used even as a base for full dentures powerful and expensive presses are necessary to mould it to the shape of the jaw. So far as is known no particular complications are likely to follow the use of stainless steel bases in the mouth when properly made and fitted, other than certain disadvantages inherent in all dentures. Electrolytic action if the stainless steel comes into contact with different metallic fillings—for example, gold and amalgam—is, however, a possibility. Acrylic resin is far easier to process, and greater accuracy in fitting can therefore be obtained more readily. Bulk for bulk it is lighter; its colour is a further advantage, and the attachment of acrylic teeth is easy. It does not, however, transmit heat in the same way, and must of necessity be more bulky in the mouth.

NOTES AND COMMENTS

Acute Nephritis and Sweating.—"RETIRED SISTER" writes: In reply to Dr. Charles Romer's remarks (November 12, p. 1128) I would like to state that we always nursed cases of both acute rheumatism and acute nephritis in blankets, the former because the patient sweated excessively and the blanket absorbed the sweat, and the latter to encourage the patient to sweat so that some of the toxins might be excreted through the skin, thus taking some of the strain off the kidneys.

Treatment of Tinea Pedis.—Dr. JOHN S. MEIGHAN (Bristol) writes: I have found the following treatment very efficient in refractory cases of tinea pedis. (1) Apply 6% silver nitrate in spirit once daily for one week. (2) Remove eschar. (3) Apply Whitfield's ointment for one week. (4) Apply silver nitrate as above for one week. (5) Apply Whitfield for one week. (6) If clear, continue with Whitfield for one month. Having tried the whole gamut of new remedies for tinea, I still think Whitfield the best.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY NOVEMBER 26 1949

THE SECRETARY REPORTS

THE REMUNERATION OF GENERAL PRACTITIONERS

The General Medical Services Committee will hold a special meeting on Thursday next, December 1, to consider the reply of the Ministry to the case approved by the Conference of Local Medical Committees for an increase in the medical pool for general practitioners. Pending the decision of the committee on the next steps to be taken, it may help to draw attention to the significance of some of the calculations in Sir William Douglas's letter published in the *Supplement* of November 19 (p. 218).

The letter began with a résumé of the calculations made before the appointed day. The total gross income of the 17,900 principals in general practice before the war was estimated by Professor Bradford Hill to be £28.14 million, of which £11.35 million was for practice expenses and £16.79 million was net income. The first step was to add the £3.1 million, the amount by which the Spens Committee thought that the remuneration of general practitioners before the war was too low. In fact, this means that the pre-war gross income of general practitioners should have been £31.24 million. To the practice-expenses element of the remuneration was added a betterment factor of 55%; to the net income there was added a betterment factor of 20%. This brought the total to £41.46 million.

As by 1948 the population had increased by some 3% over the figure for 1938, a further 3% was added to allow for this increase. This brought the total to £42.7 million. In other words, the £28.14 million, the figure for pre-war gross aggregate general practitioner income, was brought to a figure of £42.7 million by allowing for the betterment factors, the Spens recommendation, and the population increase.

But this sum of £42.7 million, being calculated from the gross pre-war general practitioner income, was earned from the whole of the community. As it was provisionally agreed for the purposes of the first two years of the Service that it should be assumed that 95% of the population would use the new Service, the sum of £42.7 million fell to be reduced by 5% so as to represent the money to be derived from public sources. Ninety-five per cent of £42.7 million is £40.57 million, which was estimated to amount to 18s. per head of 95% of the population.

So far no objection can be raised to this calculation as a matter of arithmetic *on the assumption of a 20% betterment factor on net income*. Having calculated the central pool in this way, the Ministry proceeded to add certain additional sums for maternity medical services, for the exchequer contribution to superannuation, and for the Inducement Fund. It was implicit in the Ministry's first calculation of remuneration that these should be regarded as additional to the main pool. In fact, it *offered* them as additions to the main pool. In the Ministry's present answer it takes quite a different line, for in effect it says that these (as well as others since received—e.g., increase in the mileage fund) should now be regarded as part of the total pool.

In the case to the Ministry it was asked that certain defects in the original pool calculation should be made good, notably the adjustments for betterment and for the increased number of doctors. In its reply the Ministry says that, even if these adjustments be made, our case amounts only to something in the region of £5,000,000 after taking into account the items not formerly included in the pool and, incidentally, after failing sufficiently to allow for the increased number of doctors. Having by this line of argument purported to reduce our claim to something in the region of £5,000,000. it proceeds to reject the claim.

Main Issues

Two main issues which arise from the calculations can be summarized as follows. First, having in the first instance proffered certain additional moneys over and above the pool calculation, is the Ministry entitled—now that we criticize the original pool calculation—to say that those additional moneys are really part of the pool? Secondly, has the proper adjustment been made in the Ministry's calculation for the increased number of doctors?

On the second point the Ministry has pointed out, quite rightly, that we cannot expect an adjustment both for population and the increased number of doctors. It has, in fact, allowed for an increase of 4.3% on grounds of population. It says that the doctors have increased only by 5.8% to 18,936, arguing that this amounts only to a claim for £600,000. We have asked the Ministry how it reaches the conclusion that the number of principals for the purpose of this calculation is only 18,936; on our calculation the number is 19,221.

The substance of the Ministry's reply is that, although *by the Ministry's own arguments* general practitioners are getting £4½ million less than they claimed, the Ministry tninks that no reasonable case has been made out. Lest its calculations should be successfully assaulted it proceeds to bring to its aid the argument of the national emergency. This suggests to one's mind that the Ministry is not so satisfied with the cogency of its statistical arguments as to rest its case wholly upon them.

Public Health Negotiations

At long last there are signs that the Whitley machinery for the medical profession will shortly be established. This will mean not only the translation of some of the current negotiations in the consultant and general practitioner field to the formal machinery of Whitley but—what is even more urgent—the opening of negotiations on the remuneration of the public health service.

We have seen what has happened to the school dental service as a result of the failure to adapt the remuneration of school dentists to modern conditions and to the remuneration in other branches of the same profession. We are determined that no such fate shall befall the public health service. In practice this means that every effort must be made properly to relate the remuneration of the public health service to the remuneration obtaining—as a result of the application of the Spens Reports—in consultant practice and in general practice. It is hoped that the negotiations may be opened by the end of the year.

HOSPITAL MEDICAL STAFF

Inquiries received at Headquarters reveal that there is still misunderstanding on some aspects of the terms for hospital medical staff. In anticipation of the offer of permanent contracts we shall discuss in this and succeeding issues the main points which seem to give rise to difficulty.

One matter which is not clearly understood is the way in which in certain cases the new salary scales will be applied to existing members of hospital staffs. The salary scales are as follows:

Main Scale for Consultants.—At age 32, £1,700–£2,750 by regular annual increments. Consultants appointed at 31 or earlier start at £1,550 or £1,400 respectively, and then proceed automatically along the main scale. Where a practitioner is first appointed to a consultant post after the age of 32, the board may, at its discretion, fix the initial salary at any of the four next incremental points in the scale by reason of age, special experience, and qualifications, or on age alone where seniority has been lost through service with H.M. Forces, provided that the salary may in no case be higher than the practitioner would receive on age alone.

Senior Hospital Medical Officers.—£1,300 (at 32)–£1,750.

Junior Hospital Medical Officers.—£700–£1,000.

Initial Salary

Where a member of an existing hospital staff now graded as a consultant has been continuously in consultant hospital work without a break, except one occasioned by war service (or National Service on call-up), the terms provide that the initial salary payable to him as from July 5, 1948, will be that which he would have been receiving at that time if the new scale had been operating since the date when he first obtained a hospital staff appointment with full clinical responsibility.

In practice the initial salary will be that which he would have attained on the anniversary of the date of first appointment immediately preceding July 5, 1948. Any period between those two dates which might amount to just under the 12 months is lost, because the next increment will not be payable on the anniversary of the appointment following July 5, 1948, but on July 5, 1949. This is made clear from the following illustration quoted by the Ministry:

A practitioner first appointed to a consultant post in August, 1945, at the age of 32 will start on the main scale £1,700–£2,750 on July 5, 1948, at the point £1,950, receiving his first increment on July 5, 1949:

August, 1945	August, 1946	August, 1947	July 5, 1948
£1,700	£1,825	£1,950	

Allowance for Age

Where the practitioner obtained his first consultant appointment after the age of 32, boards may exercise the same discretion that they have in the case of new entrants of fixing the initial salary at any of the four next incremental points in the scale.

Where the practitioner achieved consultant status in H.M. Forces, and obtained his first civilian hospital consultant appointment only after demobilization, the initial salary will be related to the date on which the civilian appointment was first held. But here again the employing authority has discretion to advance the initial salary where the practitioner was over 32 at the time he secured his civilian hospital appointment.

In the case of practitioners graded as S.H.M.O. there is no provision similar to that for consultants to secure that they shall receive the benefit of previous service in hospital appointments of the same level as the one now held or offered. It is in the discretion of boards to decide the point in the scale at which existing staff shall start. The only proviso is that the salary shall not be higher than it would be if based on age alone.

In the case of J.H.M.O.s, however, those officers who immediately before July 5, 1948, were receiving more than the minimum of the new scale will enter the scale at the salary they were previously receiving, rounded off, at the discretion of the board, to the next incremental point. Where the salary immediately before July 5, 1948, was less than the minimum of the scale, the officer will begin at the lowest point in the scale.

Registrars

No difficulty is likely to arise in the case of registrars or junior registrars, as in those cases the salary range covers only a two-year period at most. But it is understood from the Ministry that where a practitioner now graded as a senior registrar has held the same post and carried out the same duties since before the appointed day he would enter the scale for senior registrars as on July 5, 1948, at the appropriate point, having regard to his previous service in the appointment. There is no provision in the case of registrars for augmentation of the initial salary on grounds of war service, but if subsequently a registrar obtains a consultant appointment for the first time after the age of 32 his previous experience may then be taken into account by the board in determining the initial salary.

Transferred Officers

The terms of service contain special provisions safeguarding the position of officers who were transferred under Section 68 of the N.H.S. Act, 1946, who immediately before the appointed day were receiving salaries better than those now introduced.

PROBLEMS OF ASSISTANTS

The General Medical Services Committee has set up a subcommittee to look at the problems affecting assistants (other than trainee assistants) taking part in the National Health Service.

The subcommittee would be glad to consider any points or problems which assistants wish to put forward.

ENTRY INTO PRACTICE

MEDICAL PRACTICES ADVISORY BUREAU

At the beginning of this year the Association set up the Medical Practices Advisory Bureau to help doctors establish themselves in practice, and to advise them on personal problems associated with entry into, and the conduct of, medical practice. Its service is free to members of the Association. The London office is at B.M.A. House, and there are also branches at Manchester and Edinburgh. Inquirers should write to the Medical Director at the following addresses:

B.M.A. House, Tavistock Square, London, W.C.1 (Telephone: EUSton 2111); 33, Cross Street, Manchester (Telephone: Deansgate 3691); 7, Drumsheugh Gardens, Edinburgh, 3 (Telephone: Edinburgh 33531/3).

General Practice

The report of the Bureau presented to Council on November 16 gives an account of its activities for the first nine months of this year. A survey carried out at the London office suggests that the "standing pool" of doctors seeking openings in general practice is not as large as some have thought. About 600 have applied to the London office, but only about one-third of these are likely to be suitably placed in general practice. It is virtually impossible to find openings for about one-third, and difficult for the remaining one-third. Many doctors in the last group are over 40 years old, and, as in so many other professions, age is a handicap. Nevertheless, the Bureau has suitably placed 50% of those applying in the third quarter of this year.

Another difficulty arises because established practitioners seeking assistants with view or partners want doctors with fairly well defined qualifications. Conversely, many of those seeking openings require conditions which make it very difficult to find suitable introductions without long delay.

The report cites a case of a recent vacancy in a South Coast town. The practice was industrial, but beautiful country was easily accessible. A house on a corner site was offered for sale at a reasonable price, and a half share after a short assistantship. The Bureau sent the particulars to over 100 doctors; a fortnight later the principal had received only six applications.

It has been said that the National Health Service has encouraged general practitioners to employ a succession of assistants,

and deterred them from seeking partners. The Bureau has found this to be untrue, and there seems to be an increasing tendency for the retiring doctor to want to preserve the practice as an entity by securing the introduction of a "logical successor" or by taking a partner. The demand for locums is subject to seasonal variation. For nine months of the year it exceeds the supply, while for three months the reverse is the case.

Part-time Appointments

Many doctors want part-time appointments and sessional work—e.g., medical boards, industrial appointments, and evening surgeries. The Bureau has found it difficult to meet these demands, for, except in the big cities, it is seldom asked to introduce part-time assistants. In most regions there are large panels of practitioners waiting for vacancies on medical boards.

Hospital Appointments

Hospital appointments are always advertised, and the Bureau's work in this field has been to advise applicants rather than to introduce them to particular appointments. The report considers that there is likely to be great difficulty in providing locums for hospitals unless fees comparable to those paid in general practice are obtainable.

BRITISH MEDICAL STUDENTS' ASSOCIATION

The eighth annual general meeting of the British Medical Students' Association was held at B.M.A. House, Edinburgh, on November 11–13, when 63 delegates attended, representing all but two of the 25 affiliated schools. Dr. P. Eggleton gave an interesting address on "From Laboratory to Textbook." The association was also honoured by the presence of Professor J. H. Gaddum, F.R.S., Dr. I. D. Grant, chairman of the Scottish Committee, and Dr. E. R. C. Walker, Scottish Secretary of the B.M.A., at the formal dinner held at the Edinburgh University Union.

Student Health

The B.M.S.A. has undertaken, together with the National Union of Students and other interested bodies, to investigate the possibility of arranging special facilities for tuberculous students whereby they may continue their studies as a form of occupational therapy under the supervision of a university and at the discretion of the physician in charge of the case.

Further Education and Training Grants

Several anomalies in the administration of the grants have been corrected, and the Ministry of Education has agreed to make a special concession in favour of medical students and to continue some measure of financial support to the newly qualified ex-Service houseman who is supporting a family.

The meeting appointed a Grants Secretary, who will be responsible for matters concerning the ex-Service grants and advise students in receipt of other awards.

Medical Films

The B.M.S.A. has formed a film-viewing panel to review medical films from the student point of view.

Clinical Conferences

Successful clinical conferences were held at Cardiff, Manchester, Sheffield, and Glasgow. It was decided to encourage the holding of conferences for preclinical students, thus stimulating the interest of students of all stages in the work of hospitals in other parts of the country.

British Medical Journal

The reduction in price of the *British Medical Journal* to 10s. 6d. a year for students, a concession now extended to preclinical students, was received with enthusiasm.

Help from B.M.A.

The meeting expressed its gratitude to the British Medical Association for all its interest and help during the past session, especially for the services of Mr. Vince as permanent secretary at B.M.A. House, and for the hospitality shown by the B.M.A. staff at the Edinburgh B.M.A. House for the 1949 meeting.

Elections

P. L. C. Diggory, of University College Hospital, was elected president and Jane Stanley Evans, of Cardiff, as secretary for the session 1949–50.

Heard at Headquarters

B.M.A. Gold Medallist

The decision of the Council to award the Gold Medal of the Association to a leader of the profession in New Zealand is of special interest. Dr. J. P. S. Jamieson has been practising in Nelson for thirty years. When the Labour Government came into office in New Zealand in 1935, and it seemed likely that legislation would be introduced affecting medical practice, a National Health Insurance Committee was set up by the Association out there and formulated Association policy. On this body, and in the conduct of such negotiations as the profession had with the Government, Dr. Jamieson was the acknowledged leader, and it was largely due to him that the Branch maintained a united front against the Government's clear intention to nationalize the profession and eliminate private practice. The Branch itself states that "it is now clear that but for Dr. Jamieson's personal efforts, his courage in negotiation, and his untiring advocacy of a medical service with unlimited clinical responsibility for the practitioner, the entire medical service in New Zealand would really have become a State department."

News-letter

The secretary of the Stirling and Clackmannan Local Medical Committee has started an excellent news-letter that he sends round quarterly to his constituents. He has some interesting figures to give them. In the first year of the Service 16% of the doctors there earned under £1,000; 18.5% earned £1,000–£2,000; 39.3% earned £2,000–£3,000; 9.8% earned £3,000–£4,000; 14.7% earned £4,000–£5,000; and 1% earned £5,000–£6,000. These are gross incomes earned from the National Health Service alone. The doctors' pay compared poorly with the dentists in his area, the average gross National Health Service remuneration for single-handed dentists being £5,098 for the year, that for general practitioners £2,488. In spite of this there were 22 applicants for a rural practice in the area. The secretary starts off with an admonition that we have unfortunately often heard before—more doctors should attend the meetings that are held on their behalf.

Questions Answered

Private Consultation

Q.—*If an N.H.S. patient requests a private consultation with a specialist and asks me to arrange it, am I entitled to charge a fee for doing so and also for attending at the consultation? If an operation is advised, this type of patient often wishes to arrange admission to a private ward or nursing-home and contracts to pay a fee to the surgeon. I may be asked to assist or give an anaesthetic, and will certainly be expected to visit, even if I am not allowed to supervise after-treatment. Am I to receive nothing more than a capitation fee for these services from a patient who thus does not wish to use the free consultant and hospital services available to him?*

A.—The General Medical Services Regulations preclude a practitioner from charging a fee to one of his public patients except in certain defined circumstances. The circumstances set out in the above question are not included among these exceptions, and therefore no private fee may be charged.

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, November 16, 1949

A meeting of the Council of the Association was held at B.M.A. House, London, on Wednesday, November 16, at 10 a.m., Dr. E. A. Gregg presiding.

Obituary

The Chairman referred to the long list of seven members of former Councils and one member of the present Council whose deaths had been reported since the last meeting. Many of them had given long and able service to the Association. The member of the present Council was Air-Commodore James Kyle, who since last year had represented the Medical Branch of the R.A.F. The others were Sir Crisp English, who was well known in the Metropolitan Counties Branch, Dr. W. G. Willoughby, President of the Association in 1931, Sir Richard Needham, Dr. D. E. Finlay, of Gloucester, Dr. William Lyle, of Belfast, Dr. P. T. Sutcliffe, of Stratford-on-Avon, and Dr. C. O. Hawthorne, one-time Chairman of the Representative Body. Many of them would recall in particular Dr. Hawthorne, who was distinguished by the degree of his personal service and the devotion of his great gifts to the work of the Association.

The members signified their regret by standing in silence.

Procedure at Annual Representative Meeting

Dr. Vaughan Jones moved, "That chairmen of committees presenting reports at the Annual Representative Meeting be given adequate time for the presentation to the Representative Body of such reports."

He said that this related to what took place at the end of the Harrogate meeting, but it involved no criticism of the chairman. He was convinced that some radical alterations were necessary if the Representative Body was to do its work properly. The Association had an increasing number of committees. Their number had been criticized by a correspondent in the *Journal*, but it was obvious that the writer knew nothing about committee work. The time allotted to the presentation of important committee reports in the last hour or two of the meeting was fantastic, especially having regard to the time allowed for the "pettifogging blather" which distinguished much of the business of the first two days. A proper amount of time must be allotted to the chairmen of committees. The Annual Report of Council was only a skeleton, and it was the chairmen in their presentation who gave it flesh and blood. The members and the public ought to be informed by a proper presentation of the vast volume of work which was undertaken in the Association committees.

The motion was supported by Dr. J. C. Arthur, Dr. O. C. Carter, and Dr. N. E. Waterfield, and was carried unanimously.

It was referred to the Organization Committee to consider how it could best be implemented on the understanding that the committee's considerations would be passed on to the Agenda Committee.

A Legal Co-ordinating Committee

Dr. J. A. Gorsky referred to the request from the Representative Body to the Council to consider, in view of the increasing complexity of legislation since the inception of the National Health Service, the advisability of appointing a committee of competent members to act as a legal co-ordinating committee. He commended this proposal to the Council. It was not desired or contemplated that the proposed committee should be charged with the discussion of legal matters pertaining to the work of the Association; that was covered by the terms of reference of the Legal Actions Committee of the Council and also by the memorandum and articles of association. Certain of the standing committees, including the Private Practice and the Central Consultants and Specialists Committees, had had already to discuss legal matters arising out of recent legislation, and it would be useful to have available for advice a Legal Actions Committee with enlarged membership and terms of reference. This body might appoint a subcommittee charged with the co-ordination of legal matters in the same way as a similar function in connexion with remuneration was discharged by a committee.

Dr. Wand considered that they had too many committees already; any co-ordination of this kind should be done by the Council itself.

Dr. Gorsky's proposal was lost.

The World Medical Association

Dr. J. A. Pridham, one of the Association's delegates to the recent assembly of the World Medical Association in London, said that the meeting had been singularly successful. Excellent work had been done on its behalf by the whole staff of the B.M.A. from the Secretary (Dr. Charles Hill), who was President of the Association, downwards. One fact brought out at the meeting was that nine-tenths of the finance of the Association was in dollars collected by the United States Supporting Committee, and of this a considerable proportion came from individual medical men and medical bodies in the States. He thought they would have to consider the question of a similar supporting committee in this country. It appeared that there was no machinery at present whereby the conclusions of the World Medical Association could be presented to the British Medical Association. Last year, for example, the WMA elaborated an ethical code which was called the Declaration of Geneva, but this had not come—and indeed there was no channel for it to come—before the B.M.A. He moved that it be referred to the International Relations Committee to bring before the Council proposals showing how best the Council could be informed of the work of the WMA.

The Chairman said that they were very proud of the fact that Dr. Hill was made president of the WMA, and he suggested that the Secretary be asked to prepare a memorandum on their relationship to the WMA and the ways in which they could support it and most efficiently participate in its work.

This was agreed to.

British Commonwealth Medical Conference

A report of the first meeting of the British Commonwealth Medical Conference, held at Saskatoon in June last, and attended by Dr. Dain and Dr. Hill as delegates of the B.M.A., was placed before the Council. Dr. Dain said that the Council would receive this report with considerable satisfaction. The Canadian Medical Association, which organized the meeting, had arranged a programme which made it certain that matters of interest to the various medical bodies in the Commonwealth would be discussed, and from the nature of the discussion a very large field of matters of common interest was covered. He added that the Association was becoming more and more international in its activities, and this would have to be seriously considered because it involved time and expense. But the British Commonwealth Medical Conference had made a useful start, and he hoped the B.M.A. would maintain its position as the "mother" of the Commonwealth Associations, and continue to encourage them to talk together about their problems.

Dr. Hill added that at the conference they learned a great deal from Dr. J. O. Mercer, of the New Zealand Branch, from Dr. Hunter, of Australia, and from Dr. Tonkin, of South Africa, and he thought the Dominion representatives learned a great deal about what was going on in this country. The conference was very efficiently conducted, for which thanks were mainly due to Dr. T. C. Routley and other Canadian colleagues.

The report was accepted, together with a proposal to support a similar meeting at Brisbane next year, though it was stated

that, owing to the expense involved, later conferences would probably be held only every two years.

The Nutrition Report

Lord Horder, chairman of the Committee on Nutrition, presented the report of his committee. He apologized for some delay in its presentation, but the job which the Council gave his committee was a prolonged and difficult one. It was necessary to analyse a great mass of material and to arrive at the greatest measure of agreement amongst the eminent experts on the committee. He added his own personal thanks and those of the committee to Dr. A. Macrae (Deputy Secretary), who had acted as secretary of the committee, and proposed that an acknowledgment of the value of his work should be appended to the report.

The Council approved the report of the Committee on Nutrition for publication, and endorsed Lord Horder's reference to Dr. Macrae. The Chairman said that the Council would desire to express its appreciation and thanks to Lord Horder and to his committee, and this was done by general applause.

Constitution of the Council

Dr. Pridham, as chairman of the Organization Committee, brought forward a report on the constitution of the Central Council. He reminded the Council that the last Annual Representative Meeting, while approving the principle of increased direct representation on the Council, had referred the detailed proposals back for further consideration. The committee had carefully considered the proposals again, but, apart from a proposed increase in the number of directly elected members by grouped Branches from 37 to 39, it did not suggest any modification of the plan submitted at Harrogate. The proposed number of members elected by the Representative Body remained at 13—a figure which the committee did not think should be exceeded. Occasion had been taken to put right two anomalies by increasing by one in each case the seats allocated to Yorkshire and to the Metropolitan Counties Divisions.

Dr. Wand moved that the recommendations be referred back. The Organization Committee had taken no note at all of the feeling expressed at the Representative Meeting at Harrogate. He was very anxious that some system should be devised whereby members who had been on the Council for a long time and had done excellent work, although perhaps they had not come into prominence as chairmen of committees, should not be subject to a chance defeat when they came up for re-election. To meet such cases—which would be only limited in number—some system of co-option or creation of "aldermen" should be devised.

Dr. Carter had hoped that the chairman of the Organization Committee would bring forward some new arguments to support his proposals. The only result of the debate in the Representative Body and the fresh consideration given to the subject by the committee was an increase of two in the directly elected membership. This was not an opportune moment for the cutting down of the membership elected from the Representative Body. The whole agitation which had led to these proposals started from the premise that the Association was predominantly medico-political and that members of Council must go round to their constituents talking medical politics. It would be regrettable if as a result of these changes the Council were flooded with medical politicians, to the detriment of other interests and activities.

Dr. Vaughan Jones supported the reference back for the one reason that the Organization Committee seemed to have decided that the size of the Council must be conditioned by the architecture of the council chamber; this was a wrong principle. Dr. F. Gray agreed that the size of the building should not be a governing factor, but it did serve to bring them up against the question, Was an increase in size desirable? If the view of the Organization Committee were accepted that the present size was sufficient, these proposals were the only way to tackle the situation. Dr. J. C. Arthur thought there should be some small number of seats—even if only three or four—available for co-opted members or "aldermen."

Dr. Pridham said that to refer the proposals back without any direction from the Council would be useless. In view of the great importance and growth of the autonomous bodies the Council should be broadly based on its constituency.

The Council agreed on the following proposals: that the number of members elected by members in the Branches in Great Britain and Northern Ireland be increased from 22 to 39; that the existing arrangement under which 12 members of Council are elected by grouped representatives in the Representative Body be discontinued; that two members be elected by the representatives of constituencies in Scotland, one by representatives of constituencies in Wales with Monmouthshire, and 10 by the Representative Body as a whole; that the members elected by Branches outside Great Britain and Northern Ireland be reduced from eight to seven; that the immediate past chairman of the Representative Body, the deputy chairman, and the immediate past treasurer cease to be members *ex officio*, and that the rule under which a member of Council is prevented from serving for more than six years by the same method of election be abolished.

Dr. D. R. Owen reminded the Council of a promise that the county of Cheshire should have a seat of its own. In the grouping now recommended the East Cheshire Branch shared two seats with Manchester. Dr. Pridham undertook that his committee would consider this and other adjustments in the grouping.

Dr. Wand then moved to refer to the Organization Committee the proposal that there should be provision for co-option by the Council to a certain limited number of seats, and this was agreed to. At the same time Dr. Dain pointed out that one of the reasons for reconsidering the constitution of the Council was to ensure that there should be a substantial majority of directly elected representatives. Under the present proposals, 39 out of 72 would be directly elected, and if there were only six "aldermanic" seats it would make the directly elected members only 50% of the Council.

Dr. Hale-White suggested that a Special Representative Meeting be called to discuss the constitution of the Council. This would lessen the load on the Annual Representative Meeting. At this stage in the Association's history he thought it wrong to leave the representatives out of the picture from one year's end to another. After a brief discussion, however, the idea was negatived (18 to 25).

Advertisement and Sale of Proprietary Medicines

Dr. O. C. Carter, as chairman of the Proprietary Medicines Committee, brought forward an interim report on the advertisement and sale of these preparations. He said that his committee, appointed a year ago, had had a difficult task. It had examined a British code of standards which had been devised for the guidance of newspaper proprietors to prevent the publication of advertisements which tended to mislead the public. The committee had been greatly assisted by some who were not members of the Council—notably, Professor A. A. Moncrieff. The problem had been discussed with a number of those closely connected with proprietary medicine advertising, and the committee had come to certain conclusions: that, whilst self-medication was a time-honoured habit, it was necessary to safeguard the public against its dangers and exploitations; that, although control of advertising of proprietary medicines by existing statutes was useful so far as it went, it might require to be extended in due course, and meanwhile further extension through voluntary organizations sponsored by manufacturers, advertisers, and the Press should be encouraged; and that there would be room for the appointment by the Council of a permanent medical advisory committee on proprietary medicine advertising to advise any medical adviser who might be appointed to the British Code of Standards Committee. Dr. Carter added that his committee had come definitely to the conclusion that there were now quite a number of influential men and organizations who were honestly and conscientiously trying their best to clean up what had been a reproach to the newspapers of the country. During the last eighteen months or two years, in spite of certain flagrant breaches of the code, the standard of advertising had improved.

The Council agreed to certain suggestions for transmission to the British Code of Standards Committee for amendment of the code, but rejected a proposal that the following words should be printed on every wrapper, container, or label: "If you do not obtain early and lasting relief of your symptoms, consult your doctor." Dr. Dain said that this appeared to suggest to the buyer, "Try this out, and if it is not satisfactory see your doctor." It was a dangerous suggestion. Lord Horder said that at the time he introduced a Bill into the House of Lords 10 years ago it was made perfectly plain that this anti-social campaign should either be tackled thoroughly or left alone. This was dangerous meddling and nothing more. Mr. Eric Steeler said that the proposed phrase might lend itself to a riposte: "If you don't get relief from your doctor, try —— pills."

A proposal that the British Code of Standards Committee be urged to consider the application of more stringent measures to ensure compliance with the code was agreed to, but a further recommendation—that the Council nominate an observer to attend meetings of the Code Committee, and thus ensure direct liaison between the committee and the profession—was rejected (12 to 22). On the suggestion of Sir Lionel Whitby a phrase in the report, "Self-medication by the general public is a time-honoured habit" was changed to ". . . ineradicable habit."

The chairman said that, whatever criticisms might be made of the report and the recommendations, the Council congratulated Dr. Carter and his colleagues on an excellent piece of work.

Annual Meeting Arrangements

Professor T. P. McMurray (President-elect) presented the report of the Arrangements Committee for the Annual Meeting, 1950, at Liverpool and Southport. He said that it was proposed to hold the first part of the meeting, consisting of the Annual Representative Meeting and associated Council meetings, with the Annual General Meeting and the Overseas Conference, at Southport, and the later scientific, social, and other functions at Liverpool. The Annual Representative Meeting would begin on Thursday, July 13, and end on Monday, July 17, and after Monday the meetings would be continued at Liverpool, the meetings of the Sections to cover four days. The proposals were agreed to and the sectional officers appointed.

Mr. Lawrence Abel urged that the time had come when clinical demonstrations of the kind organized in connexion with American Congresses should be introduced into the arrangements for the B.M.A. Annual Meeting. In America the medical man attending the congresses received within a few days a complete course of postgraduate education from experts in the respective subjects.

It was decided to set up a special committee to review and report on the arrangements for future scientific meetings.

Central Consultants and Specialists Committee

Mr. R. L. Newell presented a report from the Central Consultants and Specialists Committee, which, he said, had held four meetings since the last meeting of Council. The first recommendation concerned the factors to be taken into consideration in assessing merit in connexion with distinction awards. The committee had worked out a list of factors (*Supplement*, November 12, p. 212) and now recommended that these be conveyed to the Advisory Committee on Distinction Awards, and that the Advisory Committee be informed that neither the Association nor the Central or Regional Consultants and Specialists Committees wished to participate in the procedure for selecting individual consultants for merit awards. This was agreed to.

On a further recommendation, brought forward on the suggestion of the Spa Practitioners Group Committee, that a special committee should be appointed to prepare a report regarding hydrology and balneology as practised in Britain, with details of the nature and merits of each spa, the Council felt that the Group Committee itself should be the body to prepare the document, using powers of co-option, if necessary, for the purpose. Dr. R. G. Gordon suggested that the preparation of such a report might not be as easy as the recommendation made it appear.

Certain recommendations concerning amendment of the constitution of four of the Group Committees, generally to permit enlargement of representation, were agreed to.

Grading of Hospital Medical Staff

Discussion arose on the grievance of many practitioners with regard to their grading as senior hospital medical officers when they had expected to be given consultant status. One member mentioned several examples of apparent inequity which had come within his experience—a surgeon of 23 years' experience had been graded S.H.M.O., and his anaesthetist with five years' experience had been graded a consultant; of two ophthalmic surgeons the junior had been made a consultant, the senior a hospital officer.

Dr. Wand said that they had been informed that these perverse decisions were not the responsibility of the Ministry but of their own people. In his own region there was evidence that the decision in a given case did not depend upon the qualifications of the practitioner but upon the hospital at which he was working. It was the hospital which counted, and not the man at all. He suggested that a conference might be arranged to which members of grading committees would be invited.

Mr. Abel said that this matter was causing vexation throughout the country. It was a scandal that men who were doing first-class surgery, anaesthesia, or midwifery should be graded S.H.M.O.

Mr. Newell said that when this grade was first proposed it was thought of in terms of certain appointments, such as those of tuberculosis officer. Apparently there was no uniformity in the assessment. In his region much injustice had been done. He thought the remedy lay in local appeals committees, consisting of entirely independent persons.

Sir Lionel Whitby said that the Joint Committee had pressed this matter on the Ministry time and again, but had always been countered by the argument that it was their own kind who had done the grading. The facile argument had also been brought forward: "Are we to assume that the only mistakes are undergrading? If there was a review, might it not result in downgrading as well as upgrading?" The Ministry had stated that they would arrange for a review in two years' time.

After some further discussion it was agreed unanimously:

That in view of the widespread dissatisfaction reported to it as a result of the grading of those on hospital staffs on the appointed day, this Council expresses its strong approval of the action of the Joint Committee in pressing for an early review of the grading of such practitioners by new committees appointed for the purpose at the earliest possible date.

Part-time Work for Local Authorities

Dr. J. A. Gorsky presented a report from the Joint Committee (representing the Central Consultants and Specialists, Private Practice, and Public Health Committees) on a national agreement for fees for part-time work under local authorities. The report set out the original B.M.A. proposals for certain services, the original local authority offer, and the agreed fee. Dr. Gorsky said that they had got from the associations of local authorities almost all they had asked for, and their reception by the local authorities had been very cordial, but at the final meeting they were informed that the Minister had placed a veto on the date on which the national agreement might come into operation.

Dr. R. H. H. Jolly said that they had got 90% of what they originally asked for.

Dr. Vaughan Jones said that it would seem that the principle of sessional fee payment by hours for medical officers visiting establishments maintained by local authorities had been accepted. He complained that the scale of sessional fees agreed by the Council as recently as last June for industrial medical officers should have been departed from. This was likely to prejudice negotiations in other quarters. It was all very well to say that this was a national agreement and that there must be sacrifice, but why choose this particular victim?

Dr. Wand said that when the operative date for the agreement came into force it would be open to either side, one year from the commencement of the agreement, by giving three

months' notice, to have any particular aspect reconsidered. On that understanding he was prepared to let the whole thing go through.

Dr. Gorsky said that by giving way on a small point they had gained the good will of the local authorities.

The report was approved.

Relationship of Autonomous Bodies

Dr. Gregg, on behalf of the committee which was appointed by the Council to consider the situation created by the formation of autonomous bodies within the Association and their relationship to the Representative Body, presented a short report for submission to the Representative Body. The committee, after a careful examination of the subject, considered that no action should be taken at present which would disturb the position of the autonomous committees, although it might be necessary at a later stage to examine the constitutional position of these committees in relation to the Council and the Representative Body so as to ensure a single mouthpiece of the profession on common problems.

Mr. Steeler expressed some dubiety, and said that he could not help feeling that this autonomy was bad policy for the Association. The Chairman said that the history of the Insurance Acts Committee over many years did not bear out Mr. Steeler's misgivings. The report was approved.

Other Committee Reports

The report of the Building Committee, introduced by Mr. L. Dougal Callander, was largely concerned with alterations to the Scottish House. The Council agreed, subject to the approval later of the Finance Committee, to plans submitted by the Scottish Committee for the development and improvement of the house in Edinburgh at an estimated cost of £20,000.

Dr. I. D. Grant, chairman of the Scottish Committee, in moving his own report later, thanked the Council for this decision. The report of the Scottish Committee contained no recommendations, but noted a number of matters including the setting up of a joint subcommittee on the position of general practitioners in hospitals under the N.H.S.—a matter of serious concern in some areas of Scotland.

Dr. H. R. Frederick, for the Welsh Committee, reported on the steps being taken to secure an Association house in Cardiff. He added that the Welsh Committee was discussing future activities. It was anxious truly to represent the views of members in Wales and to be recognized as the central mouthpiece on general matters affecting them.

A report by the General Medical Services Committee also contained no recommendations, but recorded a very large amount of work covered in five meetings of the committee since the Council last met. Dr. Wand, the chairman, said that there had just been received a communication from the Ministry of Health refusing to grant the increase in the capitation fee which general practitioners had claimed. The question would be discussed at a special meeting of the committee on December 1.

The new chairman of the Public Health Committee, Dr. C. Metcalfe Brown, said that the committee was disappointed at the little progress which had been made in setting up Whitley machinery for the medical profession, and had taken what steps were open to it to put an end to the continued delay.

The Private Practice Committee brought forward a recommendation, which was agreed to, concerning fees for the completion of certificates under the Cremation Act—for Form "B" and for Form "C" a minimum of one guinea, plus mileage.

A memorandum of evidence, prepared by a special committee, for submission to the Committee on Industrial Health Services (the Dale Committee) was approved, and witnesses appointed.

It was agreed to set up an International Medical Visitors Bureau at Headquarters to assist practitioners from countries outside the Commonwealth when visiting the United Kingdom. Visitors from Commonwealth countries are looked after by the Empire Medical Advisory Bureau.

On the proposal of the Central Ethical Committee it was agreed that the pamphlet on "Ethics and Members of the Medical Profession" be circulated to all practitioners in the United Kingdom on qualification, to all members of the profession at present resident in the United Kingdom, and to all others who might wish to apply for it.

The Council approved a recommendation from the Colonies and Dependencies Committee that a member of the secretariat be sent to visit the West Indian Branches in the near future.

On the proposal of Dr. R. G. Gordon, for the Science Committee, it was agreed that a new Association prize be instituted to encourage research and interest in the field of industrial medicine, the prize to consist of a certificate and cheque to the value of £50, to be awarded biennially. The proposal was warmly supported by Dr. Vaughan Jones, as chairman of the Occupational Health Committee, and by Dr. H. B. Morgan, who said that it would be a happy gesture of recognition to a specialty so far grossly neglected by the medical profession.

Dr. Carter, for the Journal Committee, brought forward a proposal that the Association should take over the publication of the *British Journal of Ophthalmology* and certain associated publications, and this was agreed to.

A report by the Medical Director of the Medical Practices Advisory Bureau (Dr. L. S. Potter) was placed before the Council. (A short account of its work appears at p. 226.)

Dr. Mary Esslemont, chairman of the Committee on Nursing, introduced a report on action taken, especially in regard to the Nurses Bill. Representatives of the committee who had met members of the House of Commons had agreed that the compromise adopted in the House of Lords in regard to th finance of nurse training was the most satisfactory procedur and that it would be unwise to continue to urge the comple removal of responsibility for finance from the General Medic Council.

Two reports of considerable detail came before the Council at a late stage in its proceedings. One of them, introduced by Dr. James Fenton, was from the Joint Committee with the National Veterinary Association, and was concerned with the problem of providing safe milk of high quality. Dr. MacFeat urged that more publicity should be given to the harm wrought by unsafe milk. Only an enlightened public opinion would ensure the necessary action. It was agreed that the report should be submitted to the Government departments concerned.

The other report, placed before the Council by the Chairman, was that of the special committee set up in February last to consider the best methods of securing the applications of the recommendations of the Spens Committee to all full-time medically qualified salaried workers not remunerated wholly through the N.H.S. The report put forward a large number of recommendations which are to be made to the University Grants Committee, the Vice-Chancellor's Committee, and the Medical Research Council.

Routine reports were made by the Finance, Staffing, Office, and Public Relations Committees.

Personal

The Council resolved by a unanimous vote to award the Gold Medal of the Association to Dr. J. P. S. Jamieson, of Nelson, for his distinguished services to the profession and to the Association in New Zealand.

The Council unanimously resolved to recommend to the Representative Body that Dr. J. B. Miller, until lately its chairman, be elected a vice-president of the Association.

The thanks of the Council were conveyed to Sir Lionel Whitby, Immediate Past President, for the able and energetic way in which he had represented the Association at meetings of the Divisions of the Canadian Medical Association in the maritime provinces, and at meetings in Montreal, Toronto, Quebec, and Winnipeg.

Good wishes were expressed to Mr. Oswald Hempson on his retirement, and an appreciation of his many years of service as Solicitor to the Association. Mr. Hempson's father was Solicitor to the Association before him, and the appointment is being continued in his firm.

The Council learned with particular pleasure that on the previous day the mother of Dr. Dain had celebrated her hundredth birthday. A message of congratulations and good wishes was sent from the Council.

THE BRITISH MEDICAL GUILD

A meeting of the Board of Trustees of the British Medical Guild was held at B.M.A. House on the day of the Council meeting, November 16. Dr. E. A. Gregg was elected chairman of the Board and Dr. Frank Gray treasurer.

Dr. Hill (Secretary) gave an oral report on behalf of the executive committee. The Central Consultants and Specialists Committee had decided to establish a separate fund comparable to the National Insurance Defence Fund. The Society of Medical Officers of Health, while expressing sympathy with the general objects of the Guild, had decided not to establish a separate collecting machinery; it would advise members of the public health service to contribute directly to the Guild. The executive committee, faced with this situation, thought it would be wise, before finally deciding on the method of direct contributions, to consult with the Society of Medical Officers of Health with a view to the possibility of their falling into line with the other two main sections of the profession in themselves establishing a collecting fund from which contributions would go to the Guild. It was realized that the decision taken by the Central Consultants and Specialists Committee was one of some importance—namely, to collect their own money, in the same way as general practitioners had done in the former National Insurance Service and were now doing, no less well, in the National Health Service. The decision taken by the consultants and specialists might lead the committee to bring forward proposals for augmenting the trustees for the purpose of distributing the money.

The executive committee had finally instructed the office to prepare a draft memorandum on the subject of local organization for its consideration at the next meeting, and later it proposed to secure the establishment, at meetings of the profession called for that purpose, of local committees. It proposed, in short, not to await a crisis, but to have machinery in readiness.

The Board gave authority for certain action with regard to the banking account, and the meeting ended.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Medical Ethics

Lay Hypnotists

The question has recently been asked whether a registered medical practitioner may properly associate in his practice with a lay hypnotist. To do so would amount to "covering"; it would therefore be unethical and infringe the Warning Notice of the General Medical Council. Association with certain auxiliary workers without medical qualifications—for example, physiotherapists—is in order because they work under the supervision of a registered practitioner, but when a lay hypnotist is employed the treatment is entirely in his hands.

FELLOWSHIP FOR FREEDOM IN MEDICINE

PROPOSALS TO AMEND ACT

The first annual meeting of the Fellowship for Freedom in Medicine was held at Caxton Hall, Westminster, on November 19. Lord Horder, who presided, said that the membership now stood at 2,940; there had been an average accession of 25 members a week since the last general meeting in February. Members had been enlisted in Australia, New Zealand, South Africa, and other Dominions. Eight resignations had been received.

Close relations had been formed with the French Association for the Defence of Free Medicine. From the American Medical Association we had received an expression of good wishes. A cheque accompanied a cordial letter, which was read, from the president of the Association of American Physicians and Surgeons. Another letter was from the chairman of the Medical Society in Madison County, Indiana, congratulating the Fellowship on "its noble stand for freedom," and enclosing a cheque for £50.

Lord Horder went on to say that when the Fellowship started he had said he saw in it the possible nucleus of a body which might at long last achieve the unity of the profession. That was an ambition which had not ceased to animate him. The body which might have been expected to be a shield against State domination of medicine had dissipated its powers. On the one hand it had formed autonomous committees which had power to negotiate with the Minister individually without any reference to the controlling body of the B.M.A.—namely, the Representative Meeting; and, on the other, it had set up a ghost of itself called a Guild, in the illusion that it would afford a legal cover.

Meanwhile things were happening. The Minister had stated in the recent debate on the amending Bill that if the 5% of patients who still went to private doctors increased it would soon sabotage the Act. "It looks to me," declared Lord Horder, "as though we have only to wait a little to see the Minister sabotage the Act himself." When he had warned the profession that under the Act the Minister could by regulation doctor the patients from Whitehall he was thought to be an alarmist. But a recent order issued to a hospital stated: "The use of penicillin in this hospital must be cut down as it is so expensive."

The Rights of the Practitioner

Dr. A. C. E. Breach, chairman of a committee of the Fellowship which has been considering changes in the Act which should form the substance of an amending Bill, said the first thing was to preserve private practice on a broad basis as an alternative to the complete control of medicine by the State. Two methods commended themselves to the committee. Everyone should have the choice between (1) remaining in the Service but receiving a grant-in-aid from the State if electing to occupy a private hospital bed, together with free provision of drugs and certain appliances, and (2) opting out of the Service and receiving a refund from the State, based upon the *pro rata* cost of the Service, to enable him to make a private contract for his medical needs. This principle was endorsed by the meeting and the committee was requested to pursue its work on these lines.

The next matter was ownership of goodwill. The committee recommended an amendment to give doctors now and in the future the option to recover ownership or to build up anew the goodwill of their practices, private or State. This would involve repayment of any compensation already received and restoration of the right to sell and buy. Dr. Breach said that if only 10% of practitioners availed themselves of such option the monopoly would be effectively broken.

The meeting approved the principle, the committee to go ahead in framing amendments to recover ownership of goodwill.

Powers of the Minister

Dr. Breach said that in the report of the committee there was fully set out what "this autocrat and his successors" might do. It seemed at first that nothing short of repeal of the Act would serve, but a careful study had suggested certain changes to curb

the more objectionable powers. It was also felt that there should be an arbitration authority under a chairman of the standing of a High Court judge with power to settle all matters arising in connexion with the Service in which agreement was not reached.

Dr. C. P. Wallace at this point referred to the Ministry's reply to the demand for correct remuneration of general practitioners. He felt that a unanimous demand should go from that meeting for an immediate reference of this subject to arbitration. Dr. H. H. R. Sutherland said that he hoped no one would think that the letter from Sir William Douglas, published in the *Supplement* of November 19 (p. 218), was the last word. The General Medical Services Committee would be dealing with the matter on December 1. There were at least two lines of attack open, one by arbitration and the other by the Whitley machinery.

The following resolution was put to the meeting and carried apparently without dissent:

That in view of the unsatisfactory nature of the Ministry's reply to the general practitioners' demand for adequate remuneration this meeting calls for the immediate establishment of a court of arbitration, the constitution of which shall be agreed both by the Minister and by the profession's representatives.

The chairman's suggestion that the resolution should be sent to the Minister and to the Secretary of the B.M.A. was agreed.

The proposals for curbing the powers of the Minister were endorsed, together with a proposal for a right of appeal to the courts from decisions of the tribunal. Dr. J. A. Gorsky pointed out that the tribunal was an administrative, not a judicial, one, and as such it was required only to give its decision, not the reasons for it. Further, under Sect. 42 complaint might be made to the tribunal by "any other person," which might include the Minister of National Insurance, who could go direct to the tribunal and not to the local executive council at all.

On the general question of remuneration the committee suggested, and it was agreed, that the main principles of assessing remuneration should be laid down in the Act; for consultants full-time posts should carry pre-determined salaries, and part-time consultants should be given every facility for the development of private practice, for general practitioners the recommendation that smaller lists should carry a higher capitation fee was accepted.

Consultant Status

Dr. E. C. Warner said that many letters had been received by the Fellowship about the system of grading. The Minister had done a clever thing by getting them to grade each other and disclaiming responsibility himself. There was no question but that there had been a great attempt to get as many people as possible into the S.H.M.O. category and degrade men who had been accepted as consultants and specialists by their colleagues for years.

Mr. Reginald T. Payne spoke strongly about distinction awards as one of the worst aspects of the Service. He could not have believed that the intellectual and moral atmosphere of the profession could have degenerated so rapidly. Many of them had looked to the Royal Colleges for real leadership, but the Colleges had neglected the opportunity and had lost the respect of the profession.

Another committee proposal, that patients using the Service should pay a small fixed fee to their general practitioners for each item, was referred back to the committee after some debate. Dr. Breach considered that the suggestion was more practical than the shilling on the prescription, but other speakers suggested, in the word of one of them, that it was "dynamite" and against the whole spirit of the Fellowship.

It was agreed to include among the proposed amendments one for the provision of compensation to owners of radiological and similar practices for the loss of the right to sell them.

The report, with other recommendations, was generally approved and the committee was instructed to get on with its job.

Among other business the meeting adopted a recommendation that medical students should be admitted to the Fellowship as associate members, with a nominal fee of 2s. 6d. The executive was also asked to give consideration to a proposal that a certain selected number of lay people be admitted as associate members, and further, on the motion of Mr. Norman Lake, that liaison should be established between the Fellowship and lay organizations of similar aim—for example, the Society for Individual Freedom.

Correspondence

"Inducement Grants"

SIR,—"Inducement" grants to "doctors practising in sparsely populated areas who can only attract a small list" fall into a category apart from the inducement grants properly so called. These latter were brought out to honour the fifth recommendation of the Spens Report, which deals with the needs of areas which are "unattractive" to doctors.

The grants to "doctors in sparsely populated areas who can only attract a small list," however, belong logically and properly to the fourth recommendation of "Spens." This recommendation lays down that "the difference which has existed between the incomes of rural and urban practitioners should be reduced," and recommends that the principles and methods of the Highlands and Islands medical scheme, which operated in Scotland for thirty years, should be applied to other sparsely populated areas.

This has been mainly done (on the lines which the Spens Committee recommended) by a very substantial increase in mileage payments. There remain, however, rural practices where mileage alone does not counterpoise the very heavy overhead costs due to the geographical character of the practice area. It is in such conditions that the grants to doctors in sparsely populated areas fulfil their purpose, and the condition for this award is not "unattractiveness" as in the case of the inducement grants proper.

Country practice is in fact very "attractive" to the great majority of doctors so engaged. That is why they are country doctors in nine cases out of ten. But "Anno Bevani One," the beginning of a new calendar in medical history, left the country doctor with his practice costs higher than ever, and his income greatly lessened by the fact that all his former private patients are now State patients. What he asks is not to be "bribed" or "induced," but to be "*enabled*" to carry on his practice by additional remuneration to meet abnormally heavy practice expenses.

It should further be noted that, in the words of the statutory regulations governing them, these grants to doctors in sparsely populated rural areas are "an entitlement." The amount of the grants is discretionary, depending upon the opinion of the Minister after consultation with his Medical Practices Committee; but in the defined circumstances the grants themselves are held forth as an "entitlement" in the same sense as the capitation fees and the mileage. In the words of Dr. Gregg, Chairman of Council of the B.M.A., these grants "are not a charity but a right."

Very unfortunately, however, many country doctors have fought shy of inducement grants. The story of the "basic salary" in its present form is not a happy one, and it does not belong here, except that its shadow has fallen athwart the "inducement grants" in the minds of many doctors. In January, 1949, Dr. McFeat, the chairman of the Scottish Committee of the B.M.A., reported that in Scotland "practitioners did not like to apply for Special Inducement Fund payments because they regarded it as the acceptance of charity." In other words the grants have become associated in the minds of these doctors with a "dole" and a "means test." Now what basis is there for these suspicions? Let us see.

At his press conference on October 6 the Minister announced that he had made 57 inducement grants up to date out of the central fund of £200,000. Now it must be clearly understood that the Minister has not, as yet, made his main and final allocation of this fund. All he has sought to do as an urgent emergency measure is to meet all cases of hardship, and it is known that what he has aimed to do is to bring the net annual professional income of the doctors concerned up to £1,000. Very properly, for this interim urgent purpose, he has asked for particulars of the applicant's total professional income from all sources. Few will cavil at that. But the question that now

arises is, Now that the task of final disbursement is being approached "in the light of the amounts of money still available in the Special Inducement Fund, and of all factors governing the cases," will the "means test" still be applied?

At any rate, as a preliminary to this final allocation the Minister has asked his executive councils for detailed particulars of the applicants' professional income from all sources. Why? And what are the implications?

The Spens Report has recognized that "any satisfactory system of remuneration must involve differentiation dependent on ability and effort." But a doctor may choose (or have the choice thrust upon him by his location) to direct his ability and effort into not one but two channels. He may have, say, a comparatively small general practice "in a sparsely populated rural area" and also be a part-time specialist at a small local hospital—perhaps the only man available in that specialty for 30 or 40 miles around.

Let it be agreed that his practice is "necessary." By virtue of his agreement with the local executive council he contracts to furnish a defined range of general medical services to all the persons on his panel. By virtue of that contract, also, he is in return entitled to a defined range of remuneration. In his case that entitlement includes not only capitation fees and mileage but an "inducement" grant.

In that event, is he to be told, "Oh yes, you are entitled to £200 inducement grant, and you are meeting all your commitments in your general practice. But you are making £400 out of your specialty. Subsidize your general practice out of that."

Or to put it in another way: if the doctor in the case considered chooses to spend his surplus time as leisure in the "local" or on the golf links, will he not then get his inducement payment? But if he spends his surplus time in the pursuit of a specialty, useful to his locality, will that inducement grant then be denied to him?

Again, would it not be against the whole trend of public policy to discriminate against "earned" income? Mr. Bevan has expressed his view (rightly) that in assessing eligibility for "basic salary" the private means of the applicant should be disregarded; and presumably this would hold good also in awarding "inducement" grants. If our doctor, therefore, had a large private income from investments (or, say, from farming) he would still get his inducement grant on his "sparsely populated rural practice with a small list." Surely *a fortiori* earned medical income from sources outside his general medical practice should not be counted unto him for unrighteousness.

What are the ethics of a "means test"? That question was answered by the Minister himself in the *Daily Express* of April 24, 1937, in an article entitled "Will Nobody Listen?" "The effect of the means test," Mr. Aneurin Bevan wrote then, "is to cheat its victims of the full benefit of such employment as they can get."

Will Mr. Bevan himself listen now and act upon his convictions?—I am, etc.,

Clynderwen, Pembs. E. ROLAND WILLIAMS.

Liability in Law

SIR,—*The Times* of October 27 contains a report of Lord Justice Denning's third lecture on "Freedom under the Law," in the course of which he is reported to have said that if doctors and dentists under the National Health Service injured their patients through negligence the State would be liable to pay damages.

My contacts with medical men and lawyers lead me to think that the learned Lord Justice's observations are being misinterpreted by many members of the medical profession and are receiving a far wider construction than they can properly bear. It is wrongly assumed that a liability in the State to pay damages means an exclusive liability, and that the doctor or dentist, being relieved by the State from the personal liability which would otherwise attach to him in case of negligence, need no longer take the precautions which have hitherto been customary to guard himself against the risk of being sued for damages.

I therefore desire to emphasize that, although in some cases there may well be a liability in the State, the doctor or dentist himself is also liable to be sued and probably will be sued concurrently, since the plaintiff gains certain technical advantage in having him as a defendant.

Unhappily the matter does not stop there, because the Ministry of Health have declared it to be their policy that hospital boards should, if it is sought to make them liable for negligent acts of a doctor, take such steps as are open to them under the Law Reform (Married Women and Tortfeasors) Act, 1935, to obtain a contribution from the doctor in respect of damages that may be recovered. (Under the Act such contribution may amount to a complete indemnity.) Whatever may be said for or against this policy, it is evident that common prudence demands in even greater measure than heretofore that medical and other practitioners, whether belonging to the whole-time staff of a hospital or otherwise engaged in the National Health Service, should guard themselves against the risks, both in respect of damages and costs, of actions for negligence. The professional man, whose reputation may be at stake, cannot safely rely for his defence upon a hospital board, whose interests will conflict with his own. Not only does the State not relieve him of the burden of liability in such cases, but it now seems likely to assume the role of an assailant.

This is not the place to discuss whether Lord Justice Denning's extra-judicial observations as reported were intended to refer to all doctors and dentists engaged in the National Health Service, including general practitioners, or whether they are directed only to such doctors and dentists as are employed under a contract of service. It may well be that the narrower interpretation is the correct one, but that is a matter which may hereafter fall to be determined by the courts.—I am, etc.,

London, W.C.2. ALISTAIR FRENCH, Secretary, Medical Protection Society.

SIR,—We have frequently been told that practitioners in the N.H.S. are not Civil Servants. Yet in discussing the Crown Proceedings Act, 1947, in his recent book *Freedom under the Law* (at p. 74) Lord Justice Denning states: "It certainly means that if doctors and dentists under the National Health Service do their work negligently so that their patients are injured, the State is liable to pay damages."

This presumably means that the fund out of which N.H.S. practitioners are paid is one coming within the scope of Section 2 (6) of the Crown Proceedings Act, and that hence such a practitioner is "an officer of the Crown."

Unless the learned Lord Justice has nodded, any further arguments as to whether doctors should become Civil Servants would appear to be within the class of the proverbial behaviour with respect to the stable door.—I am, etc.,

Chester. E. M. BISKE.

Cost of Sutures

SIR,—In view of the decision that the packing of multiple sterile sutures be prohibited, individual ampoules only of suture material are obtainable. The cost of these is at least 2s. These are not obtainable on prescription form E.C.10.

One has, therefore, the doubtful privilege of paying 2s. or more for each wound sutured. Until such supplies are available under the N.H.S. we are compelled financially to refer all such cases to hospital.—We are, etc.,

D. ST. J. BOWIE. D. M. DEAN.
A. B. DUMMERE. E. FOGARTY.
C. R. F. HEWLETT. J. V. HORGAN.
T. O. HUTTON. J. H. HUMPHRIS.
King's Lynn, Norfolk. A. G. LEAKEY. P. Q. M. SPAIGHT.

Representation of Hospital Medical Staffs

SIR,—The chairman of the Central Consultants and Specialists Committee in his letter (*Supplement*, November 5, p. 206) and in his remarks as reported (*Supplement*, November 12, p. 212) missed, in his anxiety to defend the Joint Committee, the chief point of our letter in the *Supplement* of October 22 (p. 185), which was published as the only means available in the time allowed of informing other regional committees and individual specialists of the position.

Our letter made the point that the staff side of the Specialist Whitley Council, which will be the permanent body for settlement of disputes or alterations of terms of service, to be effective

and acceptable and to accord with the meaning of a Whitley Council should be democratically elected from the hospital medical staffs of the country. This assertion of an obvious and practical point of democratic principle, which would be realized if the Central Committee, a properly representative body, were to act in appointing and instructing the staff members of the Whitley Council, has not been refuted. The Central Committee, however, has now by implication confirmed its agreement with the expedient of the *ad hoc* Joint Committee acting in this way. The Western Area Regional Committee remains dissatisfied with this position, but in view of the decision of the Central Committee will determine its attitude after reference to its constituents.—We are, etc.,

C. B. S. FULLER, Chairman.
N. ROSS SMITH, Acting Hon. Secretary

S.W. Metropolitan (Western Area) Regional Consultants and Specialists Committee

Whole-time Posts

SIR,—I should like to draw attention to the fact that almost all advertisements of vacancies for pathologists specify the posts as whole-time. This may be a precedent which will later apply to other specialties. In any case it seems not unreasonable to suggest that pathologists should have the same treatment as other specialists in the National Health Service.—I am, etc.,

Wolverhampton. A. G. MARSHALL.

Mileage Rate and Basic Salary

SIR,—Various committees are in a very difficult position in determining who shall and shall not receive the basic salary. It would appear probable that all rural practitioners have a valid claim to this salary, while urban practitioners have not. It is the borderline cases which must cause most difficulty and most criticism. It seems to me that in the case of all practitioners in established practices the basic salary could be, and should be, dispensed with, and the difference in earnings be adjusted by the mileage rate alone.

This would automatically adjust the salaries of those whose practices are partly rural and partly urban or wholly the one or the other. This would necessitate an adjustment of the mileage rate to make the payment under this head sufficient to balance the possible earnings of rural and urban practitioners.

I can see no possible objection to such a scheme, but the question of how much work is involved in attending a given number of patients in either type of practice would have to be determined. In this connexion I may mention that in my practice (a purely rural one) I have almost exactly twice as many mileage units as I have patients, and, as the unit is worth approximately 1s. 5½d., I receive 2s. 11d. per patient in addition to the capitation fee. Thus if the capitation rate is 17s. I should be capable of attending approximately 85% of the number of patients which could be attended by an urban doctor doing the same amount of work; so that if the urban doctor can attend 4,000 patients I should be able to attend 3,400 patients, which would manifestly be an impossible task.

It may be contended that the urban doctor can attend efficiently and with reasonable leisure for himself only 3,000 patients, in which case I should have to attend 2,550 to make the same income. But even this is far too many, and I would contend that a doctor in a rural practice such as mine could not possibly attend more than 2,000 patients and would then be working as hard as or harder than an urban doctor attending 3,000. If this proportion 2,000:3,000 be accepted, it will be seen that I ought to receive in mileage payments 8s. 6d. per patient (4s. 3d. per unit) in order to be on a par with the urban doctor ([2,000×17s.]+[2,000×2×4s. 3d.]=£2,550) and (3,000×17s.=£2,550).

If on the other hand it is considered better to continue with the allocation of basic salaries as at present, then on a 2,000:3,000 basis a doctor in a rural district like this would receive for attending 2,000 patients £1,757 3s. (£300+[2,000 ÷ ⅔ × 17s.]) while the urban doctor with 3,000 patients would receive £2,550 (3,000×17s.). The mileage unit in such a case (at two units per patient) would have to be about 3s. 11½d. to equalize earnings.

I submit there is a case for a considerable increase in the mileage rate whether or not it is coupled with the abolition of basic salaries to those established in practice, and that the foregoing gives a fair method of estimation of what this increase should be.—I am, etc.,

Richmond, Yorks. A. F. T. ORD.

Superannuation and Partnership Shares

SIR,—I feel there must be many general practitioners working in partnership who since the N.H.S. Act came into force have not instructed their executive councils to deduct superannuation contributions from the gross practice N.H.S. income in the same proportion as that in which the income from the practice is divided.

Quite obviously two partners holding a half-share each in a practice should have the same amount deducted from them, accruing towards their eventual pension. At the moment the deductions are based on each individual cheque. Therefore a partner who by chance or design has signed the greater number of "white cards" has the bigger pension awaiting him, regardless of his practice share.—*I am, etc.*,

Lancaster. R. A. BLYTH.

**** The N.H.S. remuneration of a general practitioner who is in partnership practice will be assessed for superannuation purposes on the basis of his share of the partnership, provided particulars of the partnership deed are disclosed to the executive council.—ED., *B.M.J.*

Eccentricities

SIR,—Not being a psychiatrist, I have been puzzled for some time by the incomprehensible mental eccentricities of our administrators.

The type who decided that a doctor's fee for giving gas depends on the number of teeth the dentist is dexterous enough to extract I now place as an ordinary practical joker, though I have not yet laughed at his joke. But I cannot place the neo-statistician who decided that making a special intermediate certificate last three months instead of two would have any effect at all on the certification menace. Like Dr. Johnson, I can only attribute it to pure ignorance.

Then again, there is the type who, while doubtless joining in the Ministerial consternation at the national drug bill, evidently cannot distinguish between dispensing and a sale over the counter, and so gives the chemist (who has my sympathy in other directions) 100% profit for selling an ounce of cotton-wool, and 1,000% profit when he sells 25 aspirins. Perhaps the fellow thinks the chemist makes the aspirins himself, singly?

The type who decided that a doctor can pay for all the dressings and drugs used personally in a year for 2,000 patients out of £2 10s. is pathetic; but even he is not quite so divorced from reality as the one who wonders why children are not being vaccinated—when no one is being paid to do it.

I regret I am not myself competent to treat these cases (much as I should like to try my hand at E.C.T.), but I do know a frightfully good mental hospital.—I am, etc.,

Ashtead, Surrey. W. EDWARDS.

General Practitioners' Remuneration

SIR,—Recent public utterances by responsible men indicate that the grim realities of our economic situation will become apparent to everyone during the course of the coming year. Whatever the steps taken to avoid financial collapse, a reduction in the standard of living is inevitable. Bearing this in mind, it seems folly to allow the G.M.S. Committee to press forward the claim for an additional £16,000,000 to implement the Spens Report. If, as we all hope, the value of our money is to be kept stable, then it surely follows that a cut in our present remuneration becomes unavoidable.

On these lines it may become urgent that the present sum of £43,000,000 now allocated to the general practitioners be divided in a more equitable manner. Hardship, due to a small

list and arising from factors outside the control and remedy of the affected doctor, should be relieved.

To do this, I would suggest as a first measure that lists should be limited to 3,000, and payment withheld for any number in excess of this maximum. The balance thus accrued can be applied towards helping the less fortunate and also assisting newcomers to establish themselves in practice.

This will go a long way towards securing a more even distribution of doctors, and by stimulating competition will ensure a reasonable standard of service to the general public.—I am, etc.,

Blakeney, Glos. J. M. ASHTON.

SIR,—I respectfully submit that there is no practical significance in the contention of your correspondent, Dr. W. A. H. Bell (*Supplement*, November 12, p. 213), that the demand for increase of salary of general practitioners is unjustified.

In the first place, your correspondent appears completely to disregard the very great difference in the value of the pound sterling at the time when (1922–37) he was a panel doctor and now when its value is in the region of 6s. Moreover, he argues from a false premise when, regarding private practice, he asserts, "There is still quite a lot available." This is simply not true, and his statement would certainly *not* bear unprejudiced investigation.

I cannot, therefore, see any point in this correspondent's letter unless it be to please our present Minister of Health, and in that case why not write—not forgetting to send a copy to the Ministry—and suggest that doctors' fees should be *reduced*? There is nothing like being thorough.—I am, etc.,

London, W.4. J. C. C. LANGFORD.

SIR,—This is undoubtedly not the most opportune time to ask for more money, but Dr. Bell (*Supplement*, November 12, p. 213) does not make it sufficiently clear in his letter that it is he, living in North London, who is satisfied. Obviously he is not sufficiently informed to speak for G.P.s as a whole.

Many are more or less satisfied with their remuneration, but many others have had their incomes considerably reduced. In many areas private practice does not exist, and the posts of school medical officer, infant-welfare medical officer, etc., have been taken over by full-time men.

Dr. Bell will not get much kudos by writing to the Minister, for I am sure Mr. Bevan thinks no better of the good boys than the bad ones.—I am, etc.,

Kidderminster, Worcs. P. D. GRIFFITHS.

SIR,—If it has taken Dr. W. A. H. Bell until September 4, 1949, to learn from the *Sunday Times* that the B.M.A. is pressing for a higher remuneration for general practitioners, surely his membership of this Association, which he claims, cannot have been a very active one. If he had taken an occasional glance at the *Journal* over the past 18 months he would know that the adequate remuneration of general practitioners has been, and continues to be, one of the chief bones of contention between the profession and the Minister.

Some of Dr. Bell's rural brethren would be very grateful to know of examples of the wide scope offered in part-time appointments (divisional police surgeons, industrial medical officers, etc.) which would apply in their districts. At the same time they would like to know how they could find time for such appointments at the end of a long country round.

No doubt there are some practitioners in industrial areas who are doing better under the new Act than previously. To suggest that for this reason we should all sit back and count our blessings is to carry the philosophy of "I'm all right—let the other man sink" to an extreme.

Unity in the profession is of paramount importance, and Dr. Bell's letter will not help it. No doubt some sections of the popular press will exploit the letter as showing that general practitioners are being treated generously. The vast majority of us know otherwise, and will continue to press our case until *all* sections of the profession are able to feel as happy about the Act as is Dr. Bell.—I am, etc.,

Lewes, Sussex. J. P. MATTHEWS.

Association Notices

PROPOSED TEES-SIDE BRANCH

Notice is hereby given by the Council to all concerned of a proposal that a new Tees-side Branch should be formed, consisting of the areas of the Cleveland, Darlington, Hartlepools, and Stockton Divisions of the present North of England Branch.

Any member or body affected by this proposal and objecting thereto should write to the Secretary of the Association by December 24, 1949, stating the objection and the ground therefor.

PROPOSED TRANSFER OF WESTMORLAND DIVISION FROM THE BORDER COUNTIES BRANCH TO THE NORTH LANCASHIRE BRANCH

Notice is hereby given by the Council to all concerned of a proposal to transfer the area of the Westmorland Division from the Border Counties Branch to the North Lancashire Branch.

Any member or body affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by December 24, 1949, stating the objection and the ground therefor.

CHARLES HILL,
November 26, 1949. *Secretary*.

29	Tues.	Committee on Constitutional Position of Branches Overseas, 2 p.m.
30	Wed.	Committee on the Postgraduate Education of General Practitioners (adjourned from November 9), 10.30 a.m.

DECEMBER

1	Thurs.	Planning Subcommittee of Occupational Health Committee, 11 a.m.
1	Thurs.	Executive Subcommittee of the General Medical Services Committee, 11.15 a.m.
1	Thurs.	Remuneration Subcommittee of Occupational Health Committee, 2 p.m.
1	Thurs.	Joint Committee of the B.M.A. and the N.V.M.A., 2.30 p.m.
2	Fri.	Committee *re* Capital Punishment, 11.30 a.m.
2	Fri.	Colonies and Dependencies Committee, 2 p.m.
6	Tues.	Proprietary Medicines Committee (*Provisional*), 11 a.m.
6	Tues.	Orthopaedic Group Committee, 2 p.m.
9	Fri.	Medical War Relief Fund Committee, 2 p.m.
9	Fri.	Ophthalmic Group Committee, 2 p.m.
12	Mon.	Psychological Medicine Group Committee, 2 p.m.
15	Thurs.	Journal Committee, 2 p.m.
19	Mon.	Armed Forces Committee, 2 p.m.
22	Thurs.	Occupational Health Committee, 2 p.m.

Branch and Division Meetings to be Held

CAMBERWELL DIVISION.—At 12, Asylum Road, London, S.E., Tuesday, November 29, 8.30 p.m., Dr. S. Oram: "The Management of Heart Cases during Pregnancy."

CLEVELAND DIVISION.—At Sparks Café Royal, Middlesbrough, Thursday, December 1, 7 for 7.15 p.m., Supper followed by address by Dr. R. S. Bruce Pearson: "The Use of Antihistamine Drugs."

ISLE OF WIGHT DIVISION.—At Royal National Hospital, Ventnor, Sunday, November 27, 3.30 p.m., lecture by Dr. A. K. Miller: "Recent Advances in Treatment of Pulmonary Tuberculosis" (illustrated by films).

LANCASTER DIVISION.—At Lecture Theatre, the Storey Institute, Lancaster, Saturday, December 3, 8.15 p.m., general meeting; 8.30 p.m., B.M.A. Lecture by Dr. Stanley Alstead: "Pharmacology as a Clinical Science."

LEWISHAM DIVISION.—At Lewisham Hospital, High Street, London, S.E., Friday, December 2, 8.30 p.m., Dr. B. Gans: "Children under School Age."

SOUTH-WEST WALES DIVISION.—At St. David's Hospital, Carmarthen, Sunday, November 27, 2.30 p.m., Annual B.M.A. Lecture by Mr. D. H. Patey: "The Acute Abdomen."

SWANSEA DIVISION.—At Brangwyn Hall, Swansea, Friday, December 2, B.M.A. dinner-dance.

WEST DOWN DIVISION.—At Great Northern Hotel, Greenore, Thursday, December 1, 8.30 p.m., dinner.

LONDON SATURDAY DECEMBER 10 1949

CAN A SCIENTIFIC SOCIETY BE STABLE?*

BY

BERTRAND RUSSELL, O.M., F.R.S.

I will begin with some explanation of the question with which I am concerned. I call a society "scientific" in the degree to which scientific knowledge, and technique based upon that knowledge, affects its daily life, its economics, and its political organization. This, of course, is a matter of degree. Science in its early stages had few social effects except upon the small number of learned men who took an interest in it, but in recent times it has been transforming ordinary life with ever-increasing velocity.

I am using the word "stable" as it is used in physics. A top is "stable" so long as it rotates with more than a certain speed; then it becomes unstable and the top falls over. An atom which is not radioactive is "stable" until a nuclear physicist gets hold of it. A star is "stable" for millions of years, and then one day it explodes. It is in this sense that I wish to ask whether the kind of society that we are creating is "stable."

I want to emphasize that the question I am asking is purely factual. I am not considering whether it is better to be stable or to be unstable; that is a question of values, and lies outside the scope of scientific discussion. I am asking whether, in fact, it is probable or improbable that society will persist in being scientific. If it does, it must almost inevitably grow progressively more and more scientific, since new knowledge will accumulate. If it does not, there may be either a gradual decay, like the cooling of the sun by radiation, or a violent transformation, like those that cause novae to appear in the heavens. The former would show itself in exhaustion, the latter in revolution or unsuccessful war.

The problem is extremely speculative, as appears when we consider the time scale. Astronomers tell us that in all likelihood the earth will remain habitable for very many millions of years. Man has existed for about a million years. Therefore if all goes well his future should be immeasurably longer than his past.

Science, as pure knowledge, began about 2,500 years ago, but as a force affecting daily life it began much later—with gunpowder and the mariner's compass. It did not begin to be a really powerful cause of social change until the industrial revolution, 150 years ago. To predict on the basis of such a very brief experience is evidently hazardous. All that can be done is to pick out certain aspects of the question with a view to causing awareness of dangers and possibilities.

Broadly speaking, we are in the middle of a race between human skill as to means and human folly as to ends. Given sufficient folly as to ends, every increase in the skill required to achieve them is to the bad. The human race has survived hitherto owing to ignorance and incompetence; but, given knowledge and competence combined with folly, there can be no certainty of survival. Knowledge is power, but it is power for evil just as much as for good. It follows that, unless men increase in wisdom as much as in knowledge, increase of knowledge will be increase of sorrow.

*The Lloyd Roberts Lecture given at the Royal Society of Medicine, London, on November 29, 1949.

Causes of Instability

Possible causes of instability may be grouped under three heads: physical, biological, and psychological. I will begin with the physical causes.

Physical

Both industry and agriculture, to a continually increasing degree, are carried on in ways that waste the world's capital of natural resources. In agriculture this has always been the case since man first tilled the soil, except in places like the Nile Valley, where there were very exceptional conditions. While population was sparse, people merely moved on when their former fields became unsatisfactory. Then it was found that corpses could be used as fertilizers, and human sacrifice became common. This had the double advantage of increasing the yield and diminishing the number of mouths to be fed; nevertheless the method came to be frowned upon, and its place was taken by war. Wars, however, were not sufficiently destructive of human life to prevent the survivors from suffering, and the exhaustion of the soil has continued at a constantly increasing rate right down to our own day. At last the creation of the Dust Bowl in the United States compelled attention to the problem. It is now known what must be done if the world's supply of food is not to diminish catastrophically. But whether what is necessary will be done is a very doubtful question. The demand for food is so insistent, and the immediate profit so great, that only a strong and intelligent government can enforce the required measures; and in many parts of the world governments are not both strong and intelligent. I am for the present ignoring the population problem, which I shall consider presently.

Raw materials, in the long run, present just as grave a problem as agriculture. Cornwall produced tin from Phoenician times until very lately; now the tin of Cornwall is exhausted. Light-heartedly, the world contents itself with observing that there is tin in Malaya, forgetting that that too will be used up presently. Sooner or later all easily accessible tin will have been used up, and the same is true of most raw materials. The most pressing, at the moment, is oil. Without oil a nation cannot, with our

present techniques, prosper industrially or defend itself in war. The supply is being rapidly depleted, and will be used up even more swiftly in the wars that are to be expected for possession of such supplies as will remain. Of course I shall be told that atomic energy will replace oil as a source of power. But what will happen when all the available uranium and thorium have done their work of killing men and fishes?

The indisputable fact is that industry—and agriculture in so far as it uses artificial fertilizers—depends upon irreplaceable materials and sources of energy. No doubt science will discover new sources as the need arises, but this will involve a gradual decrease in the yield of a given amount of land and labour, and in any case is an essentially temporary expedient. The world has been living on capital, and so long as it remains industrial it must continue to do so. This is one inescapable though perhaps rather distant source of instability in a scientific society.

BIOLOGICAL

I come now to the biological aspects of our question. If we estimate the biological success of a species by its numbers it must be admitted that Man has been most remarkably successful. In his early days Man must have been a very rare species. His two great advantages—the capacity of using his hands to manipulate tools, and the power of transmitting experience and invention by means of language—are slowly cumulative: at first there were few tools and there was little knowledge to transmit; moreover, no one knows at what stage language developed. However that may be, there were three great advances by means of which the human population of the globe was increased. The first was the taming of the animals that became domestic; the second was the adoption of agriculture; and the third was the industrial revolution. By means of these three advances men have become enormously more numerous than any species of large wild mammal. Sheep and cattle owe their large numbers to human care; as competitors with man large mammals have no chance, as appears from the virtual extinction of the buffalo.

In addressing a medical audience, it is with trepidation that I advance my next thesis, which is this. Medicine cannot, except over a short period, increase the population of the world. No doubt if medicine in the fourteenth century had known how to combat the Black Death the population of Europe in the latter half of the fourteenth century would have been larger than it was. But the deficiency was soon made up to its Malthusian level by natural increase. In China, European and American medical missions do much to diminish the infant death rate; the consequence is that more children die painfully of famine at the age of five or six. The benefit to mankind is very questionable. Except where the birth-rate is low the population in the long run depends upon the food supply and upon nothing else. In the Western world the fall in the birth rate has for the time being falsified Malthus's doctrine. But until lately this doctrine was true throughout the world, and it is still true in the densely populated countries of the East.

What has science done to increase population? In the first place, by machinery, fertilizers, and improved breeds it has increased the yield per acre and the yield per man-hour of labour. This is a direct effect. But there is another which is perhaps more important, at least for the moment. By improvement in means of transport it has become possible for one region to produce an excess of food while another produces an excess of industrial products or raw materials. This makes it possible—as for instance in our own country—for a region to contain a larger population than its own food resources could support. Assuming free mobility of persons and goods, it is only necessary that the whole world should produce enough food for the population of the whole world, provided the regions of deficient food production have something to offer which the regions of surplus food production are willing to accept in exchange for food. But this condition is apt to fail in bad times In Russia, after the first world war, the peasants had just about the amount of food they wanted for themselves, and would not willingly part with any of it for the purchase of urban products. At that time, and again during the famine in the early '30s, the urban population was kept alive only by the energetic use of armed force. In the famine, as a result of government action, millions of peasants died of starvation; if the government had been neutral the town-dwellers would have died.

Such considerations point to a conclusion which, it seems to me, is too often ignored. Industry, except in so far as it ministers directly to the needs of agriculture, is a luxury: in bad times its products will be unsaleable, and only force directed against food-producers can keep industrial workers alive, and that only if very many food-producers are left to die. If bad times become common, it must be inferred that industry will dwindle and that the industrialization characteristic of the last 150 years will be rudely checked

But bad times, you may say, are exceptional, and can be dealt with by exceptional methods. This has been more or less true during the honeymoon period of industrialism, but it will not remain true unless the increase of population can be enormously diminished. At present the population of the world is increasing at about 58,000 per diem, or about 20 millions per annum. War, so far, has had no very great effect on this increase, which continued throughout each of the world wars. Until the last quarter of the nineteenth century this increase was more rapid in advanced countries than in backward ones, but now it is almost wholly confined to very poor countries. Of these, China and India are numerically the most important, while Russia is the most important in world politics. But I want, for the present, to confine myself, so far as I can, to biological considerations, leaving world politics on one side

What is the inevitable result if the increase of population is not checked? There must be a very general lowering of the standard of life in what are now prosperous countries. With that lowering there must go a great diminution in the demand for industrial products. Detroit will have to give up making private cars, and confine itself to lorries. Such things as books, pianos, watches will become the rare luxuries of a few exceptionally powerful men—notably those who control the army and the police. In the end there will be a uniformity of misery, and the Malthusian law will reign unchecked. The world having been technically unified, population will increase when world harvests are good, and diminish by starvation whenever they are bad. Most of the present urban and industrial centres will have become derelict, and their inhabitants, if still alive, will have reverted to the peasant hardships of their mediaeval ancestors. The world will have achieved a new stability, but at the cost of everything that gives value to human life.

Are mere numbers so important that, for their sake, we should patiently permit such a state of affairs to come about? Surely not. What, then, can we do? Apart from certain deep-seated prejudices, the answer would be obvious. The nations which at present increase rapidly should be encouraged to adopt the methods by which, in the West, the increase of population has been checked

Educational propaganda, with government help, could achieve this result in a generation. There are, however, two powerful forces opposed to such a policy: one is religion, the other is nationalism. I think it is the duty of all who are capable of facing facts to realize, and to proclaim, that opposition to the spread of birth control, if successful, must inflict upon mankind the most appalling depth of misery and degradation, and that within another fifty years or so.

I do not pretend that birth control is the only way in which population can be kept from increasing. There are others, which, one must suppose, opponents of birth control would prefer. War, as I remarked a moment ago, has hitherto been disappointing in this respect, but perhaps bacteriological war may prove more effective. If a Black Death could be spread throughout the world once in every generation survivors could procreate freely without making the world too full. There would be nothing in this to offend the consciences of the devout or to restrain the ambitions of nationalists. The state of affairs might be somewhat unpleasant, but what of that? Really high-minded people are indifferent to happiness, especially other people's. However, I am wandering from the question of stability, to which I must return.

There are three ways of securing a society that shall be stable as regards population. The first is that of birth control, the second that of infanticide or really destructive wars, and the third that of general misery except for a powerful minority. All these methods have been practised: the first, for example, by the Australian aborigines; the second by the Aztecs, the Spartans, and the rulers of Plato's Republic; the third in the world as some Western internationalists hope to make it and in Soviet Russia. (It is not to be supposed that Indians and Chinese like starving, but they have to endure it because the armaments of the West are too strong for them.) Of these three, only birth control avoids extreme cruelty and unhappiness for the majority of human beings. Meanwhile, so long as there is not a single world government there will be competition for power among the different nations. And as increase of population brings the threat of famine national power will become more and more obviously the only way of avoiding starvation. There will therefore be blocs in which the hungry nations band together against those that are well fed. That is the explanation of the victory of communism in China.

These considerations prove that a scientific world society cannot be stable unless there is a world government.

It may be said, however, that this is a hasty conclusion. All that follows directly from what has been said is that, unless there is a world government which secures universal birth control, there must from time to time be great wars, in which the penalty of defeat is widespread death by starvation. That is exactly the present state of the world, and some may hold that there is no reason why it should not continue for centuries. I do not myself believe that this is possible. The two great wars that we have experienced have lowered the level of civilization in many parts of the world, and the next is pretty sure to achieve much more in this direction. Unless, at some stage, one power or group of powers emerges victorious and proceeds to establish a single government of the world with a monopoly of armed force, it is clear that the level of civilization must continually decline until scientific warfare becomes impossible—that is, until science is extinct. Reduced once more to bows and arrows, *Homo sapiens* might breathe again, and climb anew the dreary road to a similar futile culmination.

The need for a world government, if the population problem is to be solved in any humane manner, is completely evident on Darwinian principles. Given two groups, of which one has an increasing and the other a stationary population, the one with the increasing population will (other things being equal) in time become the stronger. After victory, it will cut down the food supply of the vanquished, of whom many will die.* Therefore there will be a continually renewed victory of those nations that, from a world point of view, are unduly prolific. This is merely the modern form of the old struggle for existence. And given scientific powers of destruction, a world which allows this struggle to continue cannot be stable.

PSYCHOLOGICAL

The psychological conditions of stability in a scientific society are to my mind quite as important as the physical and biological conditions, but they are much more difficult to discuss, because psychology is a less advanced science than either physics or biology. Nevertheless, let us make the attempt.

The old rationalist psychology used to assume that if you showed a man quite clearly that a certain course of action would lead to disaster for himself he would probably avoid it. They also took for granted a will to live, except in a negligible minority. Chiefly as a result of psycho-analysis this Benthamite belief that most men pursue their own interest in a more or less reasonable way has not now the hold on informed opinion that it formerly had. But not very many people, among those concerned with politics, have applied modern psychology to the explanation of large-scale social phenomena. This is what I propose, with much diffidence, to attempt.

Consider, as the most important illustration, the present drift towards a third world war. You are arguing, let us say, with an ordinary cheerful non-political and legally sane person. You point out to him what can be done by atom bombs, what Russian occupation of Western Europe would mean in suffering and destruction of culture, what poverty and what regimentation would result even in the event of a fairly quick victory. All this he fully admits, but nevertheless you do not achieve the result for which you had hoped. You make his flesh creep, but he rather enjoys the sensation. You point out the disorganization to be expected, and he thinks: "Well, anyhow, I shan't have to go to the office every morning." You expatiate on the large number of civilian deaths that will take place, and while, in the top layer of his mind, he is duly horrified, there is a whisper in a deeper layer: "Perhaps I shall become a widower, and that might be not so bad." And so, to your disgust, he takes refuge in archaic heroism, and exclaims:

> "Blow wind! come wrack!
> At least we'll die with harness on our back,"

or whatever more prosaic equivalent he may prefer.

Psychologically, there are two opposite maladies which have become so common as to be dominant factors in politics. One is rage, the other listlessness. The typical example of the former was the mentality of the Nazis; of the latter, the mentality in France which weakened resistance to Germany before and during the war. In less acute forms these two maladies exist in other countries, and are,

*Some may think this statement unduly brutal. But if they will look up newspapers of three or four years ago they will find, side by side, indignant letters saying that British labour could not be efficient on a diet of 2,500 calories, and that it was preposterous to suppose that a German needed more than 1,200 calories.

I think, intimately bound up with the regimentation which is associated with industrialism. Rage causes nations to embark on enterprises that are practically certain to be injurious to themselves; listlessness causes other nations to be careless in warding off evils, and generally disinclined to undertake anything arduous. Both are the outcome of a deep malaise resulting from lack of harmony between disposition and mode of life.

One cause of this malaise is the rapidity of change in material conditions. Savages suddenly subjected to European restraints not infrequently die from inability to endure a life so different from what they have been accustomed to. When I was in Japan in 1921 I seemed to sense in the people with whom I talked, and in the faces of the people I met in the streets, a great nervous strain, of the sort likely to promote hysteria. I thought this came from the fact that deep-rooted unconscious expectations were adapted to old Japan, whereas the whole conscious life of town-dwellers was devoted to an effort to become as like Americans as possible. Such a maladjustment between the conscious and the unconscious was bound to produce discouragement or fury, according as the person concerned was less or more energetic. The same sort of thing happens wherever there is rapid industrialization; it must have happened with considerable intensity in Russia.

But even in a country like our own, where industrialism is old, changes occur with a rapidity which is psychologically difficult. Consider what has happened during my lifetime. When I was a child telephones were new and very rare. During my first visit to America I did not see a single motor-car. I was 39 when I first saw an aeroplane. Broadcasting and the cinema have made the life of the young profoundly different from what it was during my own youth. As for public life, when I first became politically conscious Gladstone and Disraeli still confronted each other amid Victorian solidities, the British Empire seemed eternal, a threat to British naval supremacy was unthinkable, the country was aristocratic and rich and growing richer, and Socialism was regarded as the fad of a few disgruntled and disreputable foreigners.

For an old man, with such a background, it is difficult to feel at home in a world of atomic bombs, communism, and American supremacy. Experience, formerly a help in the acquisition of political sagacity, is now a positive hindrance, because it was acquired in such different conditions. It is now scarcely possible for a man to acquire slowly the sort of wisdom which in former times caused "elders" to be respected, because the lessons of experience become out of date as fast as they are learnt. Science, while it has enormously accelerated outward change, has not yet found any way of hastening psychological change, especially where the unconscious and subconscious are concerned. Few men's unconscious feels at home except in conditions very similar to those which prevailed when they were children.

Rapidity of change, however, is only one of the causes of psychological discontent. Another, perhaps more potent, is the increasing subordination of individuals to organizations, which, so far, has seemed to be an unavoidable feature of a scientific society. In a factory containing expensive plant, and depending upon the closely co-ordinated labour of many people, individual impulses must be completely controlled except by the men constituting the management. There is no possibility, in working hours, of either adventure or idleness. And even outside working hours the opportunities are few for most people. Getting from home to work and from work to home takes time; at the end of the day there is neither time nor money for anything very exciting. And what is true of workers in a factory is true, in a greater or less degree, of most people in a well-organized modern community. Most people, when they are no longer quite young, find themselves in a groove—like the man in the limerick, "not a bus, not a bus, but a tram." Energetic people become rebellious, quiet people become apathetic. War if it comes, offers an escape. I should like a Gallup poll on the question: "Are you more or less happy now than during the war?" This question should be addressed to both men and women. I think it would be found that a very considerable percentage are less happy now than then.

This state of affairs presents a psychological problem which is too little considered by statesmen. It is hopeless to construct schemes for preserving peace if most people would rather not preserve it. As they do not admit, and perhaps do not know, that they would prefer war, their unconscious will lead them to prefer specious schemes that are not likely to achieve their ostensible purpose.

The difficulty of the problem arises from the highly organic character of modern communities, which make each dependent upon all to a far greater degree than in pre-industrial times. This makes it necessary to restrain impulse more than was formerly necessary. But restraint of impulse, beyond a point, is very dangerous: it causes destructiveness, cruelty, and anarchic rebellion. Therefore, if populations are not to rise up in a fury and destroy their own creations ways must be found of giving more scope for individuality than exists for most people in the modern world. A society is not stable unless it is on the whole satisfactory to the holders of power and the holders of power are not exposed to the risk of successful revolution. But it is also not stable if the holders of power embark upon rash adventures, such as those of the Kaiser and Hitler. These are the Scylla and Charybdis of the psychological problem, and to steer between them is not easy. Adventure, yes; but not adventure inspired by destructive passions.

Conclusions

Let us now bring together the conclusions which result from our inquiry into the various kinds of conditions that a scientific society must fulfil if it is to be stable.

First, as regards physical conditions. Soil and raw materials must not be used up so fast that scientific progress cannot continually make good the loss by means of new inventions and discoveries. Scientific progress is therefore a condition, not merely of social progress, but even of maintaining the degree of prosperity already achieved. Given a stationary technique, the raw materials that it requires will be used up in no very long time. If raw materials are not to be used up too fast, there must not be free competition for their acquisition and use but an international authority to ration them in such quantities as may from time to time seem compatible with continued industrial prosperity. And similar considerations apply to soil conservation.

Second, as regards population. If there is not to be a permanent and increasing shortage of food, agriculture must be conducted by methods which are not wasteful of soil, and increase of population must not outrun the increase in food production rendered possible by technical improvements. At present neither condition is fulfilled. The population of the world is increasing, and its capacity for food production is diminishing. Such a state of affairs obviously cannot continue very long without producing a cataclysm.

To deal with this problem it will be necessary to find ways of preventing an increase in world population. It

absolute protection against the late development of jejunal ulcer has deterred us from using this very satisfactory combination more often. This fear is growing less, as we have continued to see completely successful results in following up the patients so treated. In cases where duodenal ulcers have become large and callous or have penetrated into adjacent organs, or where gross haemorrhage has occurred, we recommend vagotomy plus hemigastrectomy.

This operation is very different from the high subtotal gastrectomy now usually employed for duodenal ulcer, being neither so mutilating nor so dangerous; nor is it followed by the unpleasant small-stomach syndrome, the inability to eat a proper meal, and the progressive weight loss now commonly seen.

It is well known that, if only half the stomach is removed for duodenal ulcer, stomal ulcer subsequently develops in about one in ten patients (Rienhoff, 1945). Such recurrences respond well to vagotomy, and its use for anastomotic ulcer has gained distinguished supporters in recent years (Allen, 1947; Maingot, 1948). In employing a combination of vagotomy and hemigastrectomy in those duodenal ulcer cases unsuitable for vagotomy alone, it is our hope that the vagotomy will reduce the anastomotic ulcer rate to a figure at least as low as that for subtotal gastrectomy, while avoiding the unsatisfactory sequelae and greater mortality of the very high gastric resection. Vagotomy alone is a suitable operation for anastomotic ulcer after earlier gastro-enterostomy or gastrectomy in the majority of cases, and has the advantage of being a much less serious or dangerous undertaking than any alternative procedure available.

The vagi should not be divided in patients in whom at laparotomy no evidence of ulcer is found, unless this is deliberately undertaken for gross antral gastritis confirmed gastroscopically and accompanied by bleeding, or for recurrence of severe symptoms after gastrojejunostomy or gastrectomy when there is evidence of chronic jejunitis.

Results

Our series of vagal resections now numbers 215, 191 of them men and 24 women (Table I). Of these, 63 have been initially combined with hemigastrectomy and 21 with gastro-enterostomy; 20 have been undertaken for anastomotic ulcer. The earliest was performed five years ago, and 65 of them over two years ago.

TABLE I.—*Types of Operation*

	Cases	Operations
Duodenal ulcer	190	
		108
		21
		61
	5	
		5
	20	
		18
		2
All lesions	215	
Vagotomy alone		131
Vago		21
Vago		63
Re-operations		
Gastro-enterostomy		5
Gastrectomy		10
For duodenal fistula		1
Total operations		231

Vagotomy Alone

Early in our series we used vagotomy alone for all duodenal ulcers and anastomotic ulcers except one or two with well-established pyloric stenosis. We now realize that several of these subjects were unsuitable. None the less, a number of those in whom we would now consider a combined operation to be indicated still show first-class results with vagotomy alone.

Before we had become well practised at the operation we often failed to achieve complete denervation by the criteria of subsequent insulin tests. Dragstedt, who with his associates has done over 500 vagus resections, still draws attention to the very great difficulty of recognizing and dividing every fibre of both vagi. However, though there were 22 incomplete divisions among our first 100 cases, we have seen only six positive insulin responses among the next 100, and none at all among the last 50.

The results of these partial operations are altogether different and essentially unpredictable, for, though the percentage of failures is high, some of our most remarkable successes have been in this group, and the complications which sometimes follow vagotomy have been rare among them.

Of the 131 cases submitted to vagotomy alone (Table II), nerve section is believed to have been complete in 105.

TABLE II.—*Results of Operations Performed Over Six Months and Up to Five Years Ago*

Operation	No.	Still Symptom-free	Better but not Symptom-free	Failures
Duodenal ulcers and anastomotic ulcers after earlier operations for duodenal ulcers				
Vagotomy alone: "insulin negative" post-operatively	71	54 (76%)	13	4 (6%)
Vagotomy alone: "insulin positive"	26	9 (35%)	5	12 (46%)
	29	25 (86%)	3	1 (3%)
ing vagotomy for anastomotic ulcer after gastrectomy, and gastrectomy for failure after vagotomy	66	58 (88%)	6	2 (3%)
Combined gastric and duodenal ulcers				
Vagotomy alone	5	3	0	2

Of these 105 probably complete vagotomies, 82 were for duodenal ulcer, 5 for combined duodenal and gastric ulcers, and 18 for anastomotic ulcers. Eleven cases of duodenal ulcer in which operation was performed less than six months ago, though satisfactory, have been excluded from analysis. In the remaining 71 duodenal ulcer cases in which vagotomy is believed to have been complete and in which the operation was done over six months and up to five years ago, 54 operations (76%) have been entirely successful, 13 have been only partially successful, and 4 have altogether failed to relieve symptoms.

Of the four complete failures, one patient had pyloric stenosis and two others developed stenosis later. These three have been re-operated upon with success, two having had hemigastrectomies and one a gastro-enterostomy. The fourth patient was relieved for only a few months by vagotomy and was then as bad as ever. At re-operation the large duodenal ulcer appeared to be soundly healed, and though a mass of scar tissue was present there was no obvious stenosis. Hemigastrectomy was performed, but the patient is still only partially relieved of his symptoms.

Of the 13 partial successes, one patient who had had a long history of severe pain and several haemorrhages was completely relieved of symptoms. Nevertheless he had a further haematemesis twelve months later. On re-exploration he was found to have a healed duodenal ulcer and several superficial gastric erosions. There was also some stenosis of the pylorus with gastric retention. Five patients have

dyspepsia from time to time, though their symptoms are not so severe as those experienced before operation. There is no *x*-ray evidence of recurrence, and the symptoms are readily controlled by simple medical measures. Two patients have occasional vomiting but no other symptom. Three have attacks of colic relieved by passage of flatus or belching. Two have intermittent diarrhoea, and, though the earlier one has now been free from trouble for six months, it is too soon to say confidently that this symptom permanently settles sooner or later.

The last of these 13 patients was operated upon two years ago for repeated haematemesis from a large but otherwise symptomless duodenal ulcer. Since operation he has not had another haemorrhage, but has not felt so well as before operation. We would not now submit such a patient to vagotomy alone.

Of the 26 patients in whom vagus resection was inadvertently incomplete, eight have been altogether free from symptoms since operation, up to five years and an average of three years ago. Five have been improved but are not symptomless and 12 have relapsed. Four of these have been submitted since to hemigastrectomy, one of them having a healed duodenal ulcer but a very large active gastric ulcer. Two others whose ulcers healed developed stenosis later and required gastro-enterostomy. Another has since had a massive haemorrhage from which he died.

We do not recommend vagotomy for patients with gastric ulcer, as we hold that there is no sound rationale for vagotomy in this condition, nor have the results of others who use it been convincingly successful.

Of the five cases of combined gastric and duodenal ulcer, three have been altogether cured for up to two years. In the other two cases the duodenal ulcers have healed, but the gastric ulcers continue to relapse. One of these has since been re-operated upon. However, it is possible to select certain patients with combined ulcers as suitable for vagotomy on the basis of the special investigations into secretion which we now make. By our present criteria neither of the two failures recorded in this group should have been vagotomized, for they both had long hypotonic stomachs showing no evidence of hyperacidity or excess of interdigestive secretion.

Vagotomy plus Gastro-enterostomy

Twenty-six patients with pyloric stenosis and active ulcers have had gastro-enterostomy with or after vagotomy, seven subsequently proving to have incomplete nerve section. A further 10 have had vagotomies for anastomotic ulcers after earlier gastro-enterostomy, so that there are 36 patients with this ultimate combination in the follow-up, which ranges, in their case, up to 4½ years. The only failure in this group has been due to the persistence of vomiting in one patient in whom nerve section was incomplete. Three others, two of whom also had positive insulin responses after operation, have periods when they are not altogether symptom-free. We have not used vagotomy for patients with pyloric stenosis and healed ulcers.

Vagotomy plus Hemigastrectomy

Sixty-three patients with large callous or penetrating ulcers have had vagotomy plus hemigastrectomy, and 10 have had vagotomies for recurrent ulcers after earlier gastrectomy. A further 10 patients have had gastrectomies later for the failures after vagotomy described above—one for a gastric ulcer which did not heal, one for haemorrhage from gastric erosions, four for pyloric stenosis, and four who relapsed after incomplete vagotomy. In all, 83 have had gastric and vagal resection. The follow-up of this group is relatively short, only the earliest having been operated on more than two years ago. So far the results on the whole have been very satisfactory, though one patient who had had two partial gastrectomies and two other operations for ulcer before he came to us was not much benefited by vagotomy. Six other patients continue to have intermittent symptoms less troublesome than their earlier ulcer distress. No case of anastomotic ulcer has yet been seen.

Other Effects of Vagotomy

Vagus section has had the unexpected effect of relieving constipation. Of the patients in the series 50% complained of chronic constipation, and 90% of these have developed regular habits since operation. In two patients constipation has returned after a few months of initial relief. Diarrhoea lasting one week or sometimes two weeks has occurred in several patients, but in only four (under 2%) has it persisted for longer or been really troublesome, and these patients consider themselves better off than before the operation.

Gain in weight over the immediate pre-operative level has averaged 5 lb. (2.27 kg.) in the first six months after vagus resection alone. After vagotomy plus hemigastrectomy it has averaged 4½ lb. (2 kg.) in the same period This compares very favourably with the weight charts seen after subtotal gastrectomy (Johnson, 1948b).

Two patients who had suffered for several years from pulmonary tuberculosis as well as duodenal ulcer were operated upon at the request of their physicians because their nutrition could not be maintained at a satisfactory level for combating their infection. One has gained 14 lb (6.35 kg.) in three months and the other 16 lb. (7.25 kg.) in 12 months since operation.

Complications.—The complications specific to vagotomy are nearly always mild and transitory, but are of special interest owing to the difficulty of explaining them on physiological grounds. Some patients notice that the stomach and bowel contain an excessive amount of wind, causing frequent eructation and passage of flatus, and occasionally giving rise to bowel colic. This condition, in our experience, has nearly always settled in a few months. If patients are closely questioned many will admit having had several sudden attacks of weakness, sometimes accompanied by sweating and trembling, and lasting twenty minutes, during the first few weeks after operation. In three or four cases these attacks have persisted, occurring about once a week, usually about 3 or 4 p.m., and often after heavy exercise They were accompanied by low blood-sugar levels in two patients tested during attacks (Johnson, 1948b). Hypoglycaemia is a condition to which duodenal ulcer patients have a tendency without operation.

Mortality

There has been no death from vagotomy alone in this series (Table III). One elderly patient died from retention

TABLE III.—*Mortality*

	No.	Deaths	Mortality (%)
Vagotomy alone	131	0	0
Combined operations: Vagotomy plus gastrectomy or gastro-enterostomy ..	84	1	1·2
Re-operations .. .. (Gastrectomy, 10; gastro-enterostomy, 5; for duodenal fistula, 1)	16	1	6·2
All operations	231	2	0·87

of urine and uraemia following a combined hemigastrectomy and vagotomy, and a second died from an operation for closure of a duodenal fistula which developed after a difficult Billroth I gastrectomy with which vagotomy had also been combined. The overall mortality during the surgical treatment of these 215 patients has therefore been under 1%.

Commentary

The results of the investigations here recorded represent five years of study. During the first year little success was achieved beyond the development of a technique for complete vagus nerve section from below the diaphragm.

The percentage of failures among the early cases was high, but as the technique improved the proportion of incomplete vagotomies decreased, as did the proportion of failures. During the second and third years close follow-ups revealed the limitations of vagus resection as a therapeutic procedure in the treatment of duodenal ulcer, and some of the complications of vagotomy were recognized. Drainage operations were avoided at first, except when gross organic stenosis made it obligatory, until the effects of vagotomy alone had been studied. The observations made in this second period showed beyond question that complete vagotomy resulted in a marked fall in free acid, and that the low acid level was maintained in patients submitted to repeated secretion tests over a period of two years; but it also showed that in spite of a marked fall in free-acid level 25% of patients continued to complain of ulcer symptoms or suffered from recurrence after an initial period of well-being. Furthermore, it was noted that while 75% of vagotomized patients remained free from ulcer symptoms, certain side-effects of an unpleasant nature were apt to appear.

During the third and fourth years of study an analysis of good and bad results suggested that some of those who had been subjected to vagotomy were unsuitable subjects and that others presented too complicated a picture to be dealt with adequately by vagotomy alone, and combined operations were undertaken, such as vagotomy plus gastric resection or gastro-enterostomy.

The remaining period has confirmed that early uncomplicated cases of duodenal ulcer associated with high interdigestive secretion of free acid may be expected to obtain lasting benefit from vagotomy alone. For patients with a history of haemorrhage, perforation, scarring or deep crater formation—in other words, those most often presented to the surgeon—more radical operations are indicated. The results of these combined operations have been most gratifying, and the substitution of partial for high subtotal gastrectomy has done much to lower the post-operative morbidity and mortality of ulcer surgery.

Though resection plus vagotomy is the operation of choice at the moment, a prolonged follow-up of those patients who have had vagotomy plus gastro-enterostomy may prove that this is an adequate procedure with a minimal risk of stomal ulcer. Until this can be established beyond doubt, however, resection plus vagotomy must continue to be favoured. The scope of the resection is limited to removal of the ulcerated portion of the duodenum and enough of the pyloric half of the stomach to eliminate the secretory hormone element.

Summary

A series of 215 patients submitted to vagotomy over the last five years is reported. The results are satisfactory provided that the cases are skilfully selected and section of the nerves is complete. For large penetrating ulcers hemigastrectomy plus vagotomy has been tried, with, so far, promising results and avoidance of the "small-stomach syndrome" now becoming so common.

Despite our earlier fears, gastro-enterostomy plus vagotomy has continued to give excellent results in the small group in which it has been used.

The results of inadvertently incomplete vagotomy are variable and unsatisfactory, and only in the later part of our series did our technique become reliable in this respect

THE USE OF PROCAINE PENICILLIN WITH ALUMINIUM MONOSTEARATE IN ADULTS

BY

E. J. WAYNE, M.D., F.R.C.P.
Professor of Pharmacology and Therapeutics, University of Sheffield

J. COLQUHOUN, M.B., Ch.B.
Senior Bacteriologist, Sheffield Royal Infirmary and Hospital

AND

JOYCE BURKE, M.B., B.S., D.C.H., D.R.C.O.G.
Junior Registrar, Sheffield Royal Infirmary

Of the many attempts which have been made to prolong the action of penicillin the most successful up to the present time have involved the use of the insoluble salt formed by combining penicillin G and procaine. By the use of this salt in fine suspension in arachis oil it has been claimed that bacteriostatic levels of penicillin in the blood can be maintained for 24 hours. While there is no doubt that in many cases this claim is justified, we have found in common with other observers (Emery, Stewart, and Stone, 1949) that the titre in the blood at 24 hours is very variable and often falls below the usually accepted minimum bacteriostatic level.

The retarding effect of aluminium stearate on the absorption of procaine penicillin has been pointed out by Buckwalter and Dickison (1948). The aluminium ester, which is a water-repellent, seems to produce a unimolecular envelope over the crystals and to delay their absorption Observations on this preparation have been reported by Thomas, Lyons, Romansky, Rein, and Kitchen (1948), who found that a single injection of procaine penicillin in arachis oil with 2% (w/v) aluminium stearate maintained effective blood concentrations over a longer period than similar preparations without aluminium stearate. Robinson, Hirsh, Milloff, and Dowling (1948), using a similar preparation, found that the majority of cases had assayable blood levels after 24 hours and that one-third had assayable levels after 48 hours.

In this country Young, Andrews, and Montgomery (1949) have estimated the penicillin blood level after injection of procaine penicillin in oil with aluminium stearate. Estimations were made in 65 cases at 24-hour intervals

after a single injection of 300,000 units and in four cases at four-hour intervals. The effect of aluminium stearate in delaying absorption was confirmed. Eight patients received a single injection of 2,000,000 units of this preparation of procaine penicillin. This large dosage was tolerated well, and the indication is that very high blood levels can be obtained without incurring toxic effects from the large amount of procaine which must necessarily be administered at the same time. The prolongation of the effect of procaine penicillin by aluminium stearate has also been studied in children by Emery, Rose, Stewart, and Wayne (1949), who confirmed the advantage of the preparation over simple procaine penicillin suspensions in arachis oil.

The importance of particle size in prolonging the effect of procaine penicillin has been emphasized by Welch, Hirsh, Taggart, and Smith (1947). Thomas *et al.* (1948) likewise found that with preparations containing aluminium stearate the greatest prolongation was obtained where 95% of the particles were under 5 μ in diameter. On the other hand, Young *et al.* (1949) used preparations with a particle size of 5–20 μ with satisfactory results, and state that adequate blood levels were obtained with coarse particles of 60 μ, although such preparations tended to clog needles.

We have studied the penicillin blood levels in adults after standard doses of 300,000 units and 600,000 units of procaine penicillin in arachis oil with 2% aluminium stearate. Our estimations were carried out at relatively frequent intervals during the first 24 hours, and the blood levels were compared with those obtained after 600,000 units of penicillin in aqueous solution. We have also investigated the penicillin blood levels after daily injections of 600,000 units of the oily preparations, and in these observations preparations containing three different sizes of particle have been used.

Method and Results

Serum penicillin levels were estimated by dilutions in phenol-red-glucose-serum medium (May, Voureka, and Fleming, 1947) which were inoculated with *Streptococcus pyogenes* and compared with similarly inoculated dilutions of standard penicillin in the same medium. Injections were given to ward patients and to volunteers. Except in Cases 4, 9, 11, and 12 (see Tables I and II), to which attention will be drawn, we had no reason to think that the condition from which the patient was suffering would affect the blood levels reached.

Ten patients were given 300,000 units of the preparation, and the serum penicillin levels were estimated at frequent intervals for the first 24 hours and then 12-hourly for the next two days. The results are given in Table I. Two

cases (Nos. 4 and 9) showed very high levels, which we attribute to impaired renal excretion, since Case 4 had congestive heart failure and Case 9 suffered from type II nephritis. These two cases have been excluded from the average figures, which are given in the composite graph, but they are of interest in showing the high levels reached when excretion is impaired. It will be noticed that we have taken as our minimum bacteriostatic level a concentration of penicillin of 0.06 u./ml., whereas many American observers accept a level of 0.03 u./ml. In making general statements about "bacteriostatic levels" the actual level accepted by a group of observers must clearly be taken into account.

Apart from Case 10, adequate serum levels were maintained for 24 hours, but it was realized that higher dosage might give consistently higher levels. A further 33 patients received a single injection of 600,000 units. The serum levels obtained are given in Table II. In Cases 11 and 12

the levels were so much higher than in the rest that they have been excluded from the composite curve. In Case 11 renal deficiency was present, but we could find no reason for the very high serum level at one hour in Case 12, which was a case of gout. From Table II and the composite curve it will be seen that serum levels at or above 0.06 u./ml. are present in every case at 24 hours and at or above 0.03 u./ml. at 48 hours. At 72 hours, out of 29 cases in which estimations were made, 24 had serum levels at or above 0.03 u./ml. The composite curve shows that the average level is above 0.06 u./ml. at 72 hours. For comparison, three patients were given 600,000 units of crystalline penicillin G in water; the composite curve is shown in the Chart.

We next investigated the serum levels attained with daily doses of 600,000 units of procaine penicillin and aluminium stearate for four days. For this purpose we used three preparations from different manufacturers, A, B, and C. Over 95% of the particles in preparation B were much below 5 μ in diameter and there were no large particles. This is the preparation which has been used in the investigations described above. Preparation A contained some rather large crystals, but the great majority were much below 5 μ in size. In preparation C the crystals were also

large—approximately 5–20 μ. The results are set Table III. With preparations A and B remarkably

nstant serum levels were achieved, so that the composite rve is practically level. With preparation C the levels ached were not so constant. Although the total number cases tudied is mall, we hink this esult is not lue to chance nd that small particle size is desirable. After the fourth day no further injections were given, but detectable quantities of penicillin were present in the blood 72 hours later in those cases in which estimations were made.

Serum penicillin levels were also estimated in one patient after 600,000 units of procaine penicillin with aluminium stearate both before and during the administration of caronamide in doses sufficient to give effective blood levels. The results are shown in Table IV. During caronamide administration significantly higher blood levels were achieved 36, 48, 72, and 96 hours after the penicillin had been given.

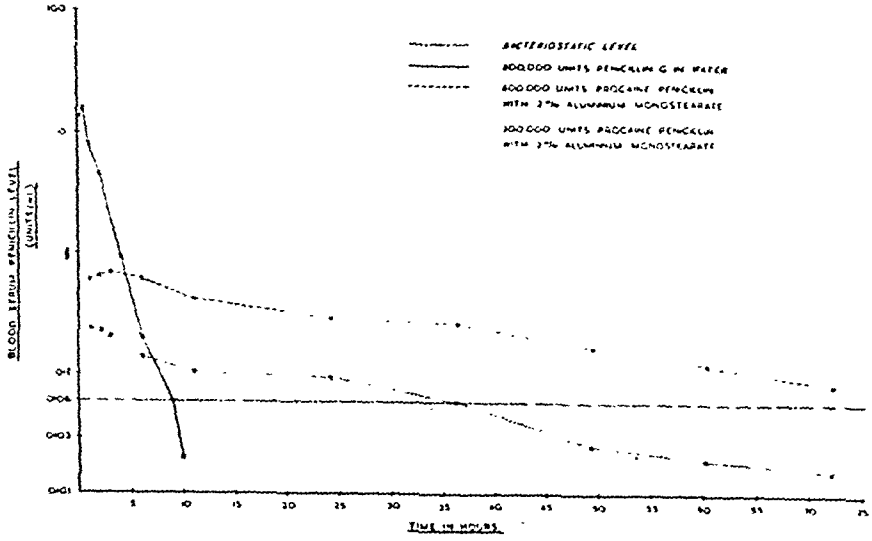

Chart showing the average serum levels of penicillin reached after single doses of 300,000 units (8 cases) and 600,000 units (31 cases) of procaine penicillin with 2% aluminium stearate. The average levels after a single dose of 600,000 units of penicillin G in water are shown for comparison. The concentration of penicillin is plotted on a logarithmic scale.

Discussion

When penicillin was first introduced it was assumed that the best clinical results would be obtained by maintaining a level of penicillin in the blood which was always above the minimum bacteriostatic level for the organism causing the disease. Consequently, continuous intravenous and, later, intramuscular drips were used. It then became abundantly clear that equally good clinical results could be obtained by the intermittent intramuscular injection of penicillin every three hours during the day and night. With the necessity for conserving the limited supplies of penicillin then available, this method was undoubtedly justified, but later, when it was possible to use much higher doses, it became the custom in general practice to give no more than two injections in each 24 hours. Indeed, it would rarely have been possible to treat patients in their own homes by any other system of dosage.

By this method clinically satisfactory results can be obtained in many minor disorders, such as those ordinarily treated in a casualty department, and we can ourselves vouch for the adequacy of six-hourly injections of 120,000 units of penicillin in water in the treatment of pneumococcal pneumonia. Similar clinical results have been reported by other observers (Wheatley, 1947, 1949; Barclay, 1949; Tompsett, Timpanelli, Goldstein, and McDermott, 1949). It should be remembered that it was originally assumed that the best results would be obtained by maintaining a bacteriostatic level of penicillin in the blood. It has been argued that an interval without penicillin in the blood may allow dormant organisms to undergo active multiplication; for it is only at this time, as Chain and Duthie (1945) have shown, that they are susceptible to the drug. It has also been argued that the very high levels obtained after a large single dose of penicillin in aqueous solution will enable penicillin to pass into relatively avascular tissue by diffusion. The bacteriostatic action of penicillin may indeed apparently persist some time after it can no longer be detected in the blood. The evidence in favour of the discontinuous use of penicillin has been reviewed by Marshall (1948).

Eagle and Musselman (1948) and Eagle (1948), on the other hand, have brought forward evidence which suggests

that the maximum bactericidal effect of penicillin is achieved by comparatively low blood penicillin levels of the order of 0.1 u./ml., and that there is no advantage in attempting to reach higher concentrations except in the case of relatively insensitive organisms. Indeed, there may be an actual disadvantage, since with some bacteria high concentrations reduce the bactericidal effect. It cannot be said that it is yet known with certainty whether discontinuous or continuous methods of administration are preferable. Tompsett *et al.* (1949) compared the effect of 300,000 units of aqueous penicillin given twice daily with that of a single injection of 300,000 units of procaine penicillin. Both systems of treatment gave satisfactory results in pneumococcal pneumonia.

It should be pointed out, however, that almost all the clinically satisfactory results reported have been achieved with methods which give a relatively stable blood concentration, and that, so far, there is no similar mass of clinical evidence in favour of discontinuous administration. Maintenance of a steady blood penicillin level is easy to achieve by a single daily dose of the preparation we have been investigating, and if a single estimation of the blood penicillin level is made it may be assumed that this will be constant from day to day. It is possible to impose a daily peak on this steady level by adding soluble penicillin to the injection if the theoretical arguments in favour of this procedure are felt to be impressive enough.

There is evidence that in the treatment of infections with sensitive organisms penicillin in oil with aluminium stearate is clinically effective (Boger and Flippin, 1949). Mahoney (1949) states that three injections of 600,000 units give as satisfactory results in the treatment of syphilis as the standard three- or four-hourly injections. There is no reason to doubt the efficacy of the preparation in any infection provided the sensitivity of the organism is estimated and the penicillin blood level is occasionally checked. The advantages of using this preparation of penicillin are the increased comfort of the patient, who need be subjected to but one painless injection a day at the most. There is also a great saving of time of the medical and nursing staff. The aluminium stearate tends to prevent sedimentation and make the preparation more fluid.

The advocates of discontinuous therapy with aqueous penicillin advise at least two injections in 24 hours, and oral administration of penicillin involves frequent dosage with not very palatable preparations. Our limited experience with procaine penicillin in oil in adults agrees with that of Emery, Stewart, and Stone (1949) in children. They found very variable blood levels. Emery, Rose, Stewart, and Wayne (1949), however, were able to maintain bacteriostatic levels in children when procaine penicillin in oil with aluminium stearate was used, and our results in adults are again in agreement.

We have used procaine penicillin with aluminium stearate in the treatment of several cases of urinary-tract infections with good results, also in a few other infections. It would be necessary, however, to treat a large number of comparable cases by this method and by standard three-hourly injections in order to make a statistically acceptable comparison.

We have seen no reactions in any patient, and the injections are almost painless. It seems probable that the preparation will become a standard form of penicillin administration except in cases in which resistant organisms are concerned.

Summary

Procaine penicillin in arachis oil with 2% aluminium stearate has been given in single doses of 300,000 units to 10 individuals and in single doses of 600,000 units to 33 individuals. The blood-serum penicillin levels have been estimated at frequent intervals. With the lower dose, bacteriostatic levels (above 0.06 u./ml.) were maintained for 24 hours in all but one case. With the higher dose, bacteriostatic levels were maintained for 24 hours in every case, and the average level remained above 0.06 u./ml. for 72 hours.

Daily doses of 600,000 units for four days were administered to 15 patients, using preparations with three different sizes of particle. Remarkably constant bacteriostatic levels were maintained while the injections were being given, especially with preparations containing many particles of small size. Detectable quantities of penicillin were present in the serum three days after administration had ceased.

One patient received caronamide before and after a single dose of 600,000 units of procaine penicillin with 2% aluminium stearate. Significantly higher levels were reached than when caronamide was not administered.

The arguments in favour of discontinuous administration of large doses of penicillin are reviewed, and it is concluded that the balance of evidence is in favour of a maintained steady blood penicillin level such as is attained by the daily administration of 600,000 units of procaine penicillin with 2% aluminium stearate.

We should like to thank Dr. H. Brody for permission to include in our series observations on some of his cases. The penicillin preparation used in most of the investigations was kindly supplied by Imperial Chemical (Pharmaceuticals), Ltd., Manchester.

The results of an investigation to establish norms for heights and weights of infants and pre-school children has recently been published by the Department of Health of the Melbourne City Council. It is the standard practice at the health centres in the city to record and chart the weight of each child who attends, and the investigation was planned to provide information about average heights and weights in the years 1926, 1936, and 1946. The results are presented in a set of tables with accompanying graphs. The main features are: (1) The difference in the average height of males and females seems to be so great that separate norms are required. (2) There has been a considerable rise in the average height and weight of infants and pre-school children in the city of Melbourne between 1936 and 1946. Such evidence as was available suggested that there had been a smaller increase between 1926 and 1936. (3) The average weight of infants in the city of Melbourne is apparently about the same as that shown by the most recently available data from New Zealand. (4) The average weight of infants is considerably higher than that which is shown as normal on the printed graphs used at the infant-welfare centres in the State of Victoria.

HERPES ZOSTER AFTER IRRADIATION

BY

FRANK ELLIS, M.D., M.Sc., F.F.R.
Medical Director, Radiotherapy Department, London Hospital

AND

BASIL A. STOLL, M.R.C.S., D.M.R.T.&D., D.T.M.&H.
Chief Assistant, Radiotherapy Department, London Hospital

Since 1935 one of us (F. E.) has been of the opinion that clinically typical zoster occurring in patients who had received radiotherapy probably resulted from the treatment. The numerical incidence of zoster generally in the population is not known, so that statistically the point is difficult to prove; we believe, however, that there is presumptive evidence of such correlation.

Although the virus nature of zoster is now accepted, there is still a considerable difference of opinion on the importance of various factors predisposing to attack by the virus. Apart from the idiopathic type of disease occurring especially in adults, the infection may also arise after contact with a case of varicella, during the course of acute or chronic infections—e.g., influenza, pneumonia, or tabes—as a result of trauma to the skin (Klauder, 1947) or injury to the spine, and following poisoning by certain drugs—e.g., arsenic, mercury, or benzol In addition, there is some association between zoster on the one hand and various forms of reticulosis and cancer, and possibly radiotherapy, on the other. The discussion and analysis of cases which follow are an attempt to clarify this latter connexion.

Pathology of Zoster

In 1900 Head and Campbell carried out pathological examination of the nervous system at necropsy on 19 patients with zoster who died in an institution within 7 to 390 days of the appearance of the eruption. In all cases a lesion was found in the posterior spinal root ganglion corresponding to the skin area involved. In all cases of zoster of the face, either the Gasserian ganglion of the fifth nerve or the geniculate ganglion of the seventh nerve was involved. Wohlwill (1924), however, in a pathological examination of six cases of idiopathic zoster, and in four cases of secondary zoster, somewhat modified the classical conception. He demonstrated that, although involvement of the posterior root ganglion is the common lesion, in some cases the posterior root itself, the posterior horn, or the anterior branch of an intercostal nerve might alone be involved as a cause of the zoster. He thus suggested that the eruption might result from involvement of any part of the afferent portion of the reflex arc without specific involvement of the posterior root ganglion.

With reference to the evidence that the virus of varicella and that of zoster are probably identical, and bearing on the ensuing discussion, Sequeira *et al.* (1947) quote an interesting suggestion. They postulate that during an attack of chicken-pox the virus spreads throughout the body and possibly settles in the central nervous system. It lies dormant there, but may be aroused to activity by various factors, including trauma, infection, and drugs. Such a hypothesis would link together all the following factors.

Reticulosis and Zoster

Many pathological observations have been made on the development of zoster during the course of Hodgkin's disease, lymphosarcoma, and leukaemia (especially of the lymphatic type).

With regard to clinical observations, Craver and Haagensen (1932) quote seven cases in which zoster developed out of 329 cases of reticulosis treated. In five of the seven cases the zoster was preceded by exacerbation of the glandular or splenic enlargement in the neighbourhood of the ganglion involved. None of the cases showed clinical involvement of the spine by the reticulosis. These authors thus suggest the possibility that infiltration of the ganglia by the reticulosis leads to a sensitization of the nerve cells to the zoster virus. Irradiation is not suggested as a possible cause.

Halle (1930) assessed 16 cases from the literature of zoster occurring during leukaemia, and Pancoast and Pendergrass (1924) describe four cases of zoster occurring during Hodgkin's disease. The frequency of zoster in Hodgkin's disease has been variously described as 13.4% in a series of 46 cases (Baldridge and Awe, 1930) and as low as 0.64% in a series of 156 cases (Epstein and McEachern, 1937). By adding together all reported series where zoster was noted, a total of 15 cases of zoster are reported in 576 cases of Hodgkin's disease, a proportion of less than 3%. In lymphosarcoma and leukaemia the average incidence of zoster is less than 1% in a large group of cases. The variation in these figures has no definite significance, since varying numbers of cases developing zoster would be missed in each series.

Cancer and Zoster

The literature has fewer references to the association between cancer and zoster. A classical instance was noted by Charcot and Cotard (1865), who reported a case of cervical zoster associated with the presence of spinal metastases from a carcinoma of the breast. Pancoast and Pendergrass (1924) quote a case of carcinoma of the ovary with multiple metastases in which D11–L1 roots were involved by zoster. Wohlwill (1924) mentions a case of carcinoma of the stomach with involvement by carcinoma of the intercostal nerve and herpetiform eruption in the skin area supplied by that nerve. Carrière (1895) mentions a case in which zoster developed in the skin of the thigh in a case of carcinoma of the cervix uteri. Neuritis of the femoro-cutaneous nerve without infiltration by the neoplasm was shown at necropsy, and Carrière attributes the neuritis to the local action of cancer toxins. Head and Campbell (1900) and Hall (1923) mention the connexion between cancer and zoster.

The development of zoster may be the preliminary sign of the development of a tumour. Kamman (1928) describes a case of zoster of the sixth intercostal nerve which was the first sign of the development of an intradural cyst at the level of the sixth dorsal segment.

Pendergrass and Kirsh (1948), in an analysis of the results of irradiation in carcinoma of the breast, quote 16 cases of zoster in 406 patients with carcinoma mammae —a proportion of 4%. Of the 16 cases, 14 had received irradiation and 15 had zoster of the thoracic region (an interesting observation in view of the thoracic location of the primary growth). In 12 of the cases there was evidence of metastases before or after the appearance of the cutaneous disease (suggesting the possibility of involvement of the spinal ganglion by the disease), but, on the other hand, four of the patients survived for 4 to 12 years after the zoster with no signs of metastases. No hypothesis regarding the association of the zoster is hazarded.

Paracchi and Pricolo (1943) quote four cases of zoster developing in the course of carcinoma and one in the course of Hodgkin's disease. In three cases of uterine cancer the zoster involved the lumbar root area. The authors state that in all cases the herpetic eruption was on

the same side and in the same region as the spread of the tumour. All the cases had received irradiation. The follow-up in these cases is not reported, but the authors suggest that the development of zoster may be a preliminary to spread of the disease. Irradiation is not considered as a possible cause.

X Rays and Zoster

In most of the cases of zoster associated with reticulosis or with cancer previously referred to in this paper the patients had received irradiation treatment. Schreus (1926) reports a case of zoster arising within 40 days of irradiation of the neck for enlarged glands, and suggests that the effect of irradiation, resulting as it does in hyperaemia, may decrease the resistance of the root ganglia to infection with the virus or that a slumbering infection in the ganglia may be awakened. It is possible, however, that the effect of *x* rays on the skin may lead to zoster, as suggested by Klauder (1947) for mechanical injuries.

The implication of irradiation as an aetiological factor in the development of zoster may be deduced from the facts previously mentioned from Craver and Haagensen, Pendergrass, and Paracchi and Pricolo, although the authors did not accept this possibility.

With reference to the effect of irradiation upon the nerve tissue the observations of Mogilnitzky and Podljaschuk (1929, 1930) are important. They note that after irradiation of the brain of adult experimental animals by fractionated doses of *x* rays, substances such as trypan blue and saccharated ferrous oxide are able to pass from the blood into the brain tissue. This does not occur without irradiation, and the authors conclude that there is a breakdown of the haemato-encephalic barrier—the protective barrier of the brain against toxins and other poisons circulating in the blood. This experimental work supports the hypothesis of Schreus (1926).

Most reports on the effect of *x* rays on nervous tissue are based on animal experiments, but the general results of observation suggest to Warren (1943) that the direct effect of irradiation on the brain and spinal cord is very slight (nerve tissue being resistant), but the secondary effects—namely, endarteritis and thrombosis—may lead to complications. In fact, Janzen and Warren (1942), delivering up to 10,000 r of 200 kV *x* rays, showed as a result no pathological change in the peripheral nerves of rats.

An interesting observation is made by Greenfield and Stark (1948), who describe three cases of post-irradiation neuropathy occurring among 180 cases of seminoma testis treated post-operatively to the retroperitoneal region by 1-million-volt *x* rays. The patients developed a flaccid paralysis of the legs without associated sensory lesions, and there was no evidence of metastatic involvement of the region. The lesion is considered to have developed as a result of irradiation damage to the anterior horn cells, and the latent period of three to five months between completing irradiation and the development of the neuropathy suggests that the effect is not directly upon the nerve tissue but follows vascular deficiency and gliosis. The dose in the region was about 5,000 r.

This latent period of three to five months is almost exactly that which forms the peak incidence of the latent period between irradiation and zoster noted in our series of cases, thus suggesting that gliosis or late fibrosis may be associated with the development of zoster. It is of interest, however, that, in spite of the serious damage to the motor system, zoster did not develop, suggesting that some additional factor—e.g., an immunological factor—may be necessary for zoster to follow irradiation.

Analysis of Cases

The number of cases considered is 45, all developing zoster after previous irradiation. (A further 20–25 cases have been noted, but their records have been lost.) Of the total, 39 cases are of malignant disease (including 24 cases of carcinoma of the breast) and six of non-malignant disease.

Carcinoma of the Breast

This group of 24 cases provides the main and most instructive part of the study because of its homogeneity It includes two subgroups :

1. This consisted of 12 cases treated with radical mastectomy followed by post-operative deep *x* rays in all cases (Table I) In this group zoster developed some months after the prophylactic course of irradiation, there being no signs of recurrence of the disease. The group is thus a uniform series treated by a uniform surgical technique followed at an interval of two to four months by a uniform course of irradiation. In the absence of clinical signs of malignancy at the time of zoster, and accepting the evidence of the case histories that zoster was not a premonitory sign of spread of malignancy, then the neoplastic process *cannot* be incriminated in the development of the zoster in this group of cases. The clinical evidence, however, tends to incriminate the course of irradiation, as is seen later. In this respect it must be noted that the area treated includes the skin of the chest wall affected (and also the medial part of the contralateral chest wall), together with the supraclavicular and axillary gland areas. It is of interest that, with the technique used, areas of the skin supplied by roots C3–D8 (approximately) are irradiated. The upper dorsal vertebrae at the level D1–3 (approximately) are included at the edge of the field of irradiation and in some cases the spinal roots on *both* sides in this region may be irradiated (see Fig. 1). Of the 12 cases, 10 were histologically proved carcinoma, and in two the evidence was clinical only.

2. This subgroup comprised 12 cases which were treated by various methods primarily and in which different techniques of

irradiation were practised when metastases or recurrences were clinically evident or suspected (Table II). This is a much less uniform group than the previous one, but is analysed for its confirmatory relation to the other group. The presence of active neoplasm at the time of the irradiation (and possibly at

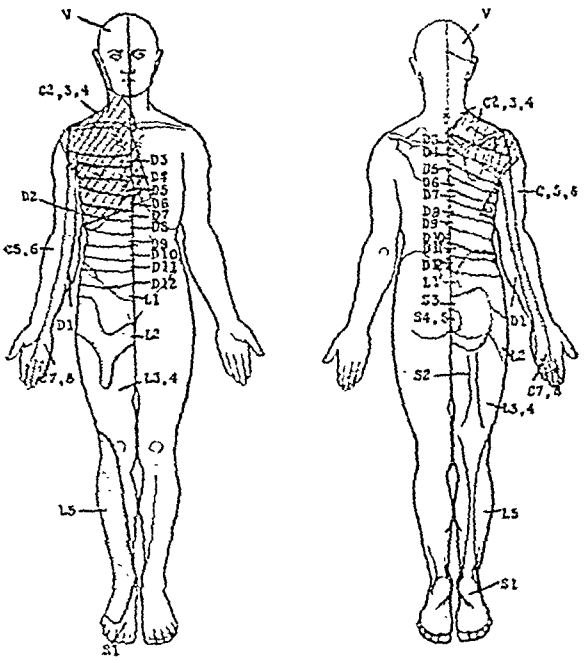

FIG. I.—The cutaneous areas supplied by the posterior nerve roots; showing skin areas irradiated in standard breast technique.

the time of the zoster) is an additional factor that may be involved in the development of zoster. Of the 12 cases in this group 10 were proved either histologically or at the death of the patient, and two were established clinically.

The analysis is carried out under four headings for the group as a whole.

I. *Site.*—The following table shows the site involved. In each subgroup separately and for both together the upper dorsal region shows the peak incidence for zoster, and in fact represents the majority of all the cases. In

	Fifth Nerve	Cervical	Upper Dorsal	Lower Dorsal	Lumbar	Not Specified	Total

" 2	1	1	7	1	—	2	12
Total ..	1	4	13	3	—	3	24

idiopathic zoster the dorsal region generally shows a greater involvement than any other site. In our group of cases, however, the large preponderance of the upper dorsal site (and also the cervical site) suggests a relationship between the zoster and the site involved by the malignant disease and treated by surgery or irradiation. In Pendergrass's series of zoster in carcinoma mammae, of the 16 cases 14 had received irradiation, and in 15 cases the dorsal region was involved. In Paracchi and Pricolo's series, of the three cases of carcinoma of the uterus, all developed zoster in the lumbar area, and all had been treated by irradiation.

II. *Side.*—There is some preponderance of involvement by the zoster on the side of the malignant lesion. Even

metastatic involvement of the spinal roots is negatived by consideration of the follow-up notes and also by the absence of any other clinical symptoms, then the effect of *x* rays on the root ganglia or on the skin of the opposite side must be considered to account for contralateral involvement. It has already been pointed out that the spinal roots of *both* sides at the level of D1–3 may be included in the field of irradiation in the post-operative breast-irradiation technique, and in addition the skin of the contralateral chest wall supplied by spinal roots D2–6 (approximately).

In this connexion Pendergrass observes that nine of the cases of zoster were on the same side as the neoplasm of the breast and three were on the opposite side.

III. *Interval Between Zoster and Previous Irradiation.*—The time interval between the last irradiation and the onset of zoster was :—subgroup 1 : 3, 3, 3, 4, 6, 8, 9, 10, 12, 13, 13, and 16 months ; subgroup 2 : 1, 2, 3, 6, 6, 9, 9, 11, 12, 12, 15, and 20 months.

It will be seen that 19 of the 24 cases developed zoster within 12 months of irradiation, and that the peak incidence is from three to nine months. This observation is even more marked when the latent intervals in the cases of upper dorsal zoster only are examined. The figures for the 13 cases in this combined group are 1, 3, 3, 3, 3, 4, 6, 6, 9, 9, 10, 12, and 12 months. It is noteworthy that all 13 cases occurred within 12 months of irradiation.

Pendergrass notes that in his series of zoster cases the incidence was from 5 to 36 months after treatment for carcinoma of the breast (none before five months). Craver notes for seven cases of zoster after irradiation in reticulosis latent intervals of 1, 3, 6, 7, 9, 18, and 36 months after treatment. Paracchi and Pricolo note for five cases of zoster after irradiation in cancer and reticulosis latent intervals of 2, 3, 5, 21, and 48 months respectively. Greenfield and Stark, in three cases of irradiation neuropathy following seminoma testis, note latent intervals of three to five months

For the malignant (other than breast) cases described later the latent intervals were 1, 2, 3, 4, 5, 5, 5, 5, 6, 8, 10, 18, 18, 43, and 60 months and for the non-malignant group described later 6, 6, 8, 11, 26, and 36 months after irradiation.

When all groups are added together the distribution is as follows :

Zoster Development

Months after treatment:	1	2	3	4	5	6	7	8	9	10	11	12	13–24	25–36	36+
No. of cases	3	3	7	2	5	7	1	3	4	2	2	3	9	3	3

The peak incidence in 57 cases of zoster after irradiation is seen to be at three to nine months (see Fig. 2). These figures apply to the time interval from the last treatment. In 16 instances previous irradiation was given, and in the graph the time interval from these treatments is shown separately.

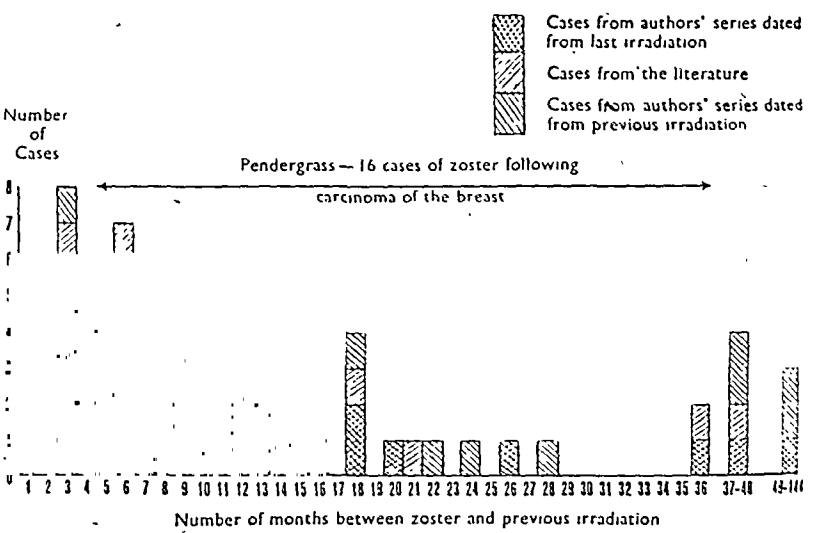

FIG 2.—The time interval between incidence of zoster and previous irradiation

IV. *Follow-up History.*—(1) Subgroup 1 :—In no case was there clinical evidence of spinal involvement either

before or after the zoster. Eight cases showed no signs of recurrence of the disease at intervals of 7, 9, 9, 10, 11, 16, 25, and 30 months after zoster (equivalent to 12, 17, 17, 20, 26, 28, 33, and 38 months after irradiation). One case developed metastases in the femur 26 months after zoster. One patient died 11 months after zoster with liver metastases. Two cases have no current follow-up record. (2) Subgroup 2:—Two cases had radiological evidence of spinal metastases, one six months and the other two years before the development of zoster. In the first case the site of the zoster has not been established, and nor could it be correlated in the second case, in which bone metastases were multiple. In the remaining 10 cases there is no evidence of spinal metastases before or after the zoster, although four patients died of metastases 1, 5, 7, and 14 months after the zoster. The remaining six patients are still alive 1, 10, 21, 24, 40, and 48 months after zoster (equivalent to 7, 19, 23, 35, 60, and 60 months after irradiation).

Malignant (Other than Breast) and Non-Malignant Cases

The 15 cases of malignant disease (Table III) vary in character and include five cases of carcinoma of the bronchus, two of carcinoma of the ovary, and one case each of lymphosarcoma of the neck, lympho-epithelioma of the nasopharynx, teratoma testis, carcinoma of the cervix, carcinoma of the bladder, secondary malignant glands of the neck, epithelioma of the forehead, and polycythaemia.

The six cases of the non-malignant group (Table IV) consist of two cases of spondylitis, two of osteoarthritis, one of syringomyelia, and one of tuberculous adenitis of the neck. Both groups are analysed together for simplicity.

I. *Site*

	Fifth Nerve	Cervical	Upper Dorsal	Lower Dorsal	Lumbar	Not Spec.	Total

	Ipsilateral	Contralateral	Unspecified	Total
Malignant ..	4	3	8	15
Non-malignant ..	—	—	6	6

III. The interval between zoster and previous irradiation has been discussed under "carcinoma of the breast," above.

IV. *Follow-up History.*—In the malignant (other than breast) group there is evidence of spinal involvement concurrently with the zoster in one case and spinal involvement one month before the zoster in a second case. In the latter case, metastases involved L2 and the zoster involved the upper dorsal region at the level of which the patient had received deep *x* ray therapy. In the residual 13 cases there is no evidence of spinal metastases before or after the zoster, although two of these patients died at intervals of 8 and 11 months after the zoster. The 11 remaining cases were alive at intervals of 2, 2, 2, 2, 3, 3, 4, 6, 9, 11, and 60 months after the zoster (equivalent to 6, 8, 9, 11, 12, 16, 20, 21, 49, 62, and 68 months after the last irradiation). The case of the nasopharyngeal tumour with fifth-nerve zoster developed sixth-nerve palsy three months after zoster, suggesting an infiltrative basis for the zoster.

Conclusions

The analysis of our cases shows: maximal incidence of zoster at the somatic level of the neoplasm, and thus of the site of irradiation; involvement by the zoster of either the same or, to a lesser extent, the side of the body opposite to that irradiated; a maximal incidence of zoster at between three and six months following the treatment, with a gradually diminishing incidence up to two years; and no evidence of malignant involvement of the posterior-nerve root within the period of observation except possibly in four cases with vertebral involvement.

The first question to be considered is whether the irradiation may be implicated as a factor in the aetiology of zoster in these cases. We consider that the time relationship between the development of the zoster and the previous irradiation, as shown in Fig. 2, provides strong evidence that this is the case. There is some interest in the fact that late irradiation reactions in all parts of the body, associated with the relative ischaemia and fibrosis which follow endothelial proliferation, usually tend to develop at an interval of three to six months after treatment. A delayed vascular deficiency and gliosis in the spinal root ganglion or delayed fibrosis in the skin with involvement of the nerve endings might cause activation of a latent zoster virus.

The second question to be considered is the way in which the irradiation may possibly be concerned in the aetiology of herpes. In this connexion we may note (especially by consideration of the breast cancer series, where the disease is primarily unilateral that: (1) The incidence of zoster in a minority of cases is on the opposite side to that treated. (2) The level of zoster in a minority of cases does not correspond with the somatic level treated. (These two findings correspond with those of Pendergrass.) (3) One or two of the upper dorsal posterior root ganglia, on *both sides*, are sometimes directly irradiated in the routine technique for irradiation in carcinoma of the breast. Even when this is so, the zoster does not necessarily correspond in level with the posterior root ganglia irradiated. (4) The skin area (and thus the cutaneous nerves also) corresponding to the level involved by zoster later has in the majority of cases been irradiated. The technique of treatment often includes a portion of the skin on the opposite side of the midline anteriorly.

In view of our first conclusion and these observed facts, it would seem that zoster may result either from a systemic mechanism following the release of substances set free by irradiation, or possibly from an effect at the level of the cord concerned, through the afferent nerves of the irradiated area. No further speculation is justified, unless in all cases a correlation were established between the site or nerve tissue irradiated and the subsequent site of zoster. (The

by the fact that the 125 pregnancies include a number which ended in early abortion. From evidence so far acquired I believe that pregnancy produced by morphologically unsatisfactory semen carries a distinctly increased risk of ending in early abortion. For the time being this can be put forward only as an opinion awaiting confirmation. A series of such cases is being collected and the findings will be published as soon as an adequate group of "normals" has been examined.

Findings in Routine Semen Tests

In 5,400 semen analyses of 3,182 men we found that 791 (24.8%) were normally fertile; 423 (13.3%) borderline; 1,711 (53.8%) *distinctly subfertile*; and 257 (8.1%) had total azoospermia. Although, as pointed out above, these figures do not represent an average sample of the population, they demonstrate the very substantial part played by male subfertility in the barren marriage.

The wives of many men in the "distinctly subfertile" and even "total azoospermia" groups had previously been subjected to prolonged investigations, and frequently attempts had been made to help matters by dilatation and curettage, ventrosuspension of the uterus, and a variety of hormone administrations. One childless woman had had two "D. and C." operations, a tubal insufflation, a salpingogram, an endometrial biopsy, and a host of injections, tablets, and douches, extending over a period of two years and costing a considerable sum, before someone thought of examining her husband. His semen contained no spermatozoa on repeated examination.

Some Common Fallacies

A considerable number of patients referred to this laboratory reported that previous attempts to investigate and treat their condition had been made and that often these had failed to clarify the situation or to improve matters. Certain types of mistakes were encountered so constantly that their discussion would seem desirable. As a rule the failure is accounted for by *inadequate* seminological technique.

Condom Specimens

For several years seminologists have been unanimous in condemning the examination of condom specimens for routine fertility assays. The rubber of condoms is known to contain substances injurious to spermatozoa, which may immobilize them quite rapidly. Nevertheless, even at the present time several laboratories accept such specimens and give reports on them. In some cases condoms are sent by post overnight.

It cannot be too emphatically stated that a specimen collected *under such conditions cannot possibly show normal features* and that any verdict on the quality of such a specimen—except that of total azoospermia—is bound to be mere guesswork. The motility of spermatozoa is one of the most important indices of their quality, and distinctly poor motility on repeated examinations would brand a specimen as subfertile no matter *how good the other features might be.*

Two patients whose semen showed normal volume, density and morphology but persistently low motility figures (1–4%) had previously been pronounced highly fertile on the evidence of condom specimens. No impairment had been found in their wives, and their marriages remained barren after four and seven years' trial.

Direct Microscopical Examination of Semen

Sometimes a patient will answer the request for a seminal specimen by saying that his doctor had looked at his semen under the microscope and found him "perfectly all right." Sometimes the semen was taken from a condom. This method is approximately as accurate as a blood picture obtained by direct microscopical examination of a more or less fresh drop of blood. In my opinion any attempt to short cut a complete semen analysis is bound to delay the discovery of the cause of a couple's failure.

Minimum Normal Findings

Density.—It is often argued that, theoretically at least, the presence of only one spermatozoon in a man's ejaculate makes him a potential father. On the other hand, a patient recently brought a report from his local hospital stating that he was sterile, as his semen contained only 8 million spermatozoa—a quite unjustifiable prognosis. It is alarming to speculate on the possible consequences of such a statement. In my series of 125 pregnancies the minimum densities are: 1½ millions before and after conception in one case, and three-quarters of a million before and 1½ millions after conception in another. In 11 other men of this group the densities ranged from 5 to 16 millions before conception, but subsequent specimens were not obtainable. Harvey and Jackson (1948) report pregnancies with repeated counts as low as 1 million. Whereas such semen findings obviously cannot be taken to indicate normal fertility—i.e., an average expectation of pregnancy—it would seem equally unwise to tell a man suffering from oligozoospermia either that he is sterile or that he needs no help.

Motility.—It is not uncommon to find that a patient has been subjected to prolonged treatment because "his spermatozoa are weak" whilst in other respects the semen is said to be normal. Usually this verdict is based on findings in a condom specimen or on one several hours old. In my experience true asthenozoospermia—i.e., poor motility without gross impairment of other features, especially morphology—is uncommon. I have records of only four men whose semen showed normal volume, density, and morphology but whose sperm motility remained persistently between 1 and 8%. Between five and eight semen tests were done in each case over a period of one to three years, and most specimens were produced at the laboratory. Two of these cases were quoted above as having been classified "highly fertile" on condom specimens.

At the other extreme, I have seen many semen analyses reporting 90% or even 100% motility. Several laboratories dealing with routine semen examinations put 80% motility as the lowest figure compatible with normal fertility. So far as I am aware, the technique of the motility count in these instances consists in counting both motile and immotile spermatozoa in a number of restricted microscopical fields.

"Pregnancy" groups A and B (see above) show a maximum motility figure of 62% in the former, and only one of the 125 cases in the latter exceeded the 70% limit. Among the remainder of the material I have occasionally found motility figures approaching the 80% mark, and in one case even exceeding it. However, these are exceptional cases, and I feel that 50% can be regarded as fully adequate.

It might be argued that the discrepancy between our findings and those of other workers is simply due to a difference in technique, and that, provided each keeps to his standards, results can still be reliable. However, I suggest that it is undesirable to rely upon a method which can produce variable results even with the same observer, and which in the past has produced most unlikely findings.

The ultimate purpose of semen examinations is not only to diagnose possible defects, but also to provide reliable indications of the patient's progress under treatment. This requires strictly comparable results from one test to the next.

Morphology

Comparable to the motility figures quoted above, the same reports are often found to record findings of 90 or 100% normal spermatozoa, and the minimum figure indicating normal fertility is stated to be 80% of normal forms. The 15 normally fertile men (group A) show a range of 16–35% of morphological abnormalities, and 60% of group B have 20–40% of abnormal spermatozoa.

Many excellent descriptions and illustrations of the various types of abnormal spermatozoa have been published. It is difficult to understand how different observers can disagree in deciding whether, say, a sperm head has a normal oval outline or is deformed; whether there is a well-marked division between the clear anterior and the darkly staining nuclear half of the head or whether it is just a pyknotic mass; whether a "collar" of cytoplasmic material surrounds the middle piece; or whether this is straight or bent—to mention only a few common and obvious features.

The following case will illustrate the practical importance of what might be regarded as an academic point.

A patient presented himself with an unusual semen condition encountered by me in only two other cases. In a specimen of normal volume and good density 98% of the sperm heads were small, spherical, and pyknotic, and more than half of them were surrounded by cytoplasm—i.e., they presented the appearance of degenerate spermatids—and the motility was poor. Yet the same patient brought two previous semen reports from a hospital running a large subfertility clinic pronouncing him normally fertile. A slide of one of his previous specimens generously loaned to us showed the same grossly abnormal features.

Furthermore, I believe that pregnancy produced by a specimen showing impaired morphology carries an increased risk of early abortion; and, whether to prove or disprove this contention, it is obviously desirable to pay the utmost attention to accurate differential counts.

The above descriptions refer only to the commonest sources of error encountered. But over and above these there are many more disagreements amongst laboratory workers and clinicians. They all tend to vitiate the attempts to provide an accurate diagnosis on which rational prognosis and treatment could be based. It is necessary to emphasize the fact that the examination of semen requires adequate time and a highly specialized technique, and that there is an urgent need for standardization of methods if our past neglect of the subfertile male is to be remedied.

Treatment

I shall discuss in some detail only two substances in common use on which the material examined has enabled me to form an opinion—namely, vitamin E and testosterone. Research is still in progress upon other methods of treatment, and it is intended to publish the results in a future report.

Vitamin E.—Forty-two unselected subfertile men, excluding only cases of azoospermia, were treated with "ephynal," a synthetic analogue of vitamin E. The doses given were from 10 to 40 mg. daily over a period of from 6 to 24 weeks. Six cases showed some improvement, seven showed some deterioration, and 29 were unchanged. Five cases in this group received additional doses of 5 mg. of methyl testosterone on alternate days at one time during the above treatment, and they were all in the "unchanged" group at the end. Subsequently, 34 cases treated with corresponding doses of natural vitamin E ("fertilol") for periods of six to ten weeks showed similar inconclusive results; the series was abandoned at this stage. Although I am not in a position to deny that more prolonged treatment—one to two years has been suggested—might not prove of some value, I do not feel justified in advocating vitamin-E therapy on the evidence available. The above figures, in my opinion, could be found in a similar untreated group Detailed figures of the "ephynal" group are published in the *Proceedings* of the Family Planning Association Conference on Infertility held at Exeter in 1948.

Testosterone.—Fifty-three unselected subfertile men, again excluding cases of total azoospermia, were given methyl testosterone in doses ranging from 5 mg. on alternate days (21 cases) to 10 mg. a day over periods of from four to eight weeks. Two cases improved, 18 (mostly reduced density) deteriorated, and 33 were unchanged. In addition to this group many cases sent to me for examination have been treated with testosterone elsewhere and sent back for re-examination. They received doses similar to the above, or injections of testosterone propionate in doses of 10–25 mg. once or twice a week, for periods up to 12 weeks, or testosterone implants. The only fairly constant effect of the larger doses, and occasionally of the lower ones, on the semen picture is a reduction of sperm density. As a rule this effect is only temporary, and, even if it is alarming to see a case of oligozoospermia reduced to azoospermia, the semen picture can usually be expected to resume its original level a few weeks after the cessation of treatment. I consider that testosterone has no place in the treatment of semen deficiencies. However, provided the dose is not excessive, some cases might benefit from the temporary increase of libido it often produces.

Treatment with the gonadotrophins would still seem to hold out some hope, but reliable figures are not yet available.

Selection of Cases for Treatment

If it is difficult to assure the patient that any form of treatment will benefit him eventually, present-day methods of investigation can produce at least two definite and useful results: first, from the beginning to exclude from treatment those men whose fertility is damaged beyond repair; and, secondly, to eliminate those forms of treatment which are certain to prove useless in a given case.

The above refers mainly to cases of total azoospermia and oligozoospermia, and I consider it unwise to attempt treatment in such cases without first performing a testicular biopsy A biopsy is a minor operation which can be performed in a few minutes at the consulting-room, clinic, or out-patient department, and leaves the patient fit to return to work next day. It is an essential step in deciding whether a case of azoospermia is due to blockage of the epididymides or vasa, or to failure of spermatogenesis. In the former case only surgical treatment is likely to help: in the latter, either absence of spermatogenic cells will prove the patient hopeless or the finding of incomplete maturation may hold out some hope of stimulating the process Again,

in a case of oligozoospermia the presence of a few fully active seminiferous tubules with complete inactivity in the remainder indicates little prospect of improvement, whereas if most tubules are found to be active, but at a reduced rate, treatment is well worth trying.

Only 128 biopsies have been performed at this laboratory to date, and if nothing has been achieved beyond the fact that 27 patients could confidently be advised to abandon treatment, I feel amply repaid by the considerable time and expense thus saved.

The subject of testicular histology and its correlation with semen findings and with the effects of treatment is likely to prove of the greatest importance. It is mentioned here only briefly, as material is being collected for a more detailed report.

Summary

A survey is made of the semen findings in 3,182 male partners of subfertile marriages, 125 of whom produced pregnancies subsequently. A separate group of 15 selected normally fertile men is described. Cases are quoted illustrating the need for adequate investigation of the male and for standardization of seminological technique.

I am indebted to Roche Products Ltd., Vitamins Ltd., Ciba Laboratories Ltd., and Organon Laboratories Ltd for the generous free supply of their products for our experimental series.

THUMB RECONSTRUCTION BY TRANSFER OF BIG TOE

BY

PATRICK CLARKSON, M.B., B.S., F.R.C.S.

Casualty Surgeon, Guy's Hospital; Plastic Surgeon, Basingstoke Plastic Centre and Royal Northern Hospital

AND

RONALD FURLONG, M.B., B.S., F.R.C.S.

Orthopaedic Surgeon, St. Thomas's Hospital

This is an interim report on the treatment of a patient whose lost thumb we have restored by a method seldom used, and one not everywhere held in good repute. Nevertheless we believe the method has advantages which should be seriously considered in cases in which restoration of a missing thumb or finger is thought to be desirable.

Nicoladoni (1900) introduced the method in 1898, and he reported an instance of successful tendon function when a toe had been used to replace an injured thumb. Gueullette (1930) reported from the literature 12 instances of the transfer of the big toe and five of the use of the second toe: there were only three good results. Five of the toes necrosed and the remainder were stiff and useless (quoted by Bunnell, 1949). We can find no record of the use of the method in this country until 1947, when J. B. Cuthbert demonstrated a successful result in a man at the Plastic Centre at Rooksdown House, Basingstoke. Cuthbert stressed the fact that selection of this method depends on the size of the big toe. A massive bulky toe is of little use because of its unpleasant appearance. Bunnell, in condemning the method, writes: "The second toe is too narrow and weak and the great toe is too gross." He draws attention to the disappointing results up to 1930, but states that he has seen one case successfully operated on by H. Hoyle Campbell, in which suture of the digital nerves had been followed by some return of sensation but without stereognosis.

The possibilities of a successful nerve suture, restoring cutaneous sensibility, and the maintenance of motion in the transferred interphalangeal joint make the method attractive. A point of great importance with many of the younger patients, particularly girls, is the appearance of the new thumb. To look well, a repaired digit must have a nail of appropriate length and skin of colour and texture approaching the normal. Other methods of reconstruction will cater for length and, to some extent, skin texture, but only by digital transfer can a nail be restored.

Unless the new thumb is elegant and functional the patient will develop "cover-up" mechanisms and will avoid use of the laboriously produced digit, which is often of more satisfaction to the surgeon than either function or appearance can justify.

Case Report

The patient was a girl aged 9. When 2 years old she fell on to an electric fire and burnt both her hands. The burning was so severe that all the digits of the left hand were destroyed. The burns of the right hand were less severe, but there was sufficient scarring and ankylosis to impair function.

Fig. 1 shows the condition of her left hand at the age of 3, in 1942. The maximum loss is in the index finger and thumb, only the epiphyses of the proximal phalanges remaining. The middle finger is represented by most of the shaft of the proximal phalanx, and the fourth and fifth fingers have been similarly destroyed.

FIG 1.—The hand at 3 years of age. Only the stump of the proximal phalanx of the thumb remains. The stumps of the medial four digits are bound to the palm. At this stage the complete palm was replaced by a dermatome graft and the digital stumps mobilized by Sir Harold Gillies.

When the child was 3 Sir Harold Gillies replaced the palmar scar by a dermatome graft. Later he deepened the first cleft by a large dorsal rotation flap with a free skin graft to the secondary defect. These operations were completely successful.

Six years later it was clear that the child could not develop a proper pick-up mechanism between the thumb stump and any digit, as the thumb stump was too short to be opposed even to the longest finger stump. Choice of this method of repair was suggested by Sir Harold Gillies, in the light of Cuthbert's case, because of the age and sex of the patient, and was influenced by the fact that her big toes were neat and not bulky. The tactics of the surgical campaign were explained to the parents so far as was possible, also the discomfort to be borne and the fact that the method was one that had seldom been used. The foot on the same side was chosen, as the hand can comfortably lie on the foot on the proper axis with less strain. The digits of both hand and foot lie parallel, and zinc oxide strapping ensures adequate fixation. The technique of the operation is described below.

Subsequently the transposed toe was shortened, with obliteration of the volar groove. The cleft between the middle and index fingers was deepened to increase their active length and aid the development of a pick-up mechanism. The extensor tendons of the thumb and transposed hallux were joined. Figs. 2, 3, 4, 5, and 6 show the appearance and condition of the hand.

FIG. 2.—The attachment. The hand is shown inserted underneath the dorsal flap. This photograph was taken a month after the attachment.

Suture of the digital nerves has yet to be done, but an appreciation of deep pressure returned to the pulp three months after operation. After 10 months there was some appreciation of pin-prick all over the pulp. Appreciation of deep pressure, which is present everywhere in the pulp, may possibly be referred from the stump of the true thumb.

The patient already has the ability to pick up and hold fairly bulky objects, such as a pencil or a fork (Fig. 5), but is handicapped by the instability of the union between graft and host. Although stability is increasing it is almost certain that a bone graft will be necessary to produce union between the phalangeal fragments. At a very much later stage it may be practical to do a flexor tendon transplant or graft.

FIG. 3.—The big toe on the hand immediately after being detached from the foot. It is too long, too thick, and there is a deep volar groove.

The colour of the new thumb is more pink than a normal one, but there is a brisk capillary response to pressure. The pulp of the toe has shrunk since transfer, and this reduction in overall bulk has improved the cosmetic appearance and produced a thumb nearer to normal size. Further thinning by surgery may yet be desirable, and is certainly practicable.

The stump of the toe on the foot is soundly healed and stable; the patient runs, dances, and plays hockey without disability.

Technique of Toe-Thumb Transfer

Method of Attachment.—In order to get a broad attachment of raw surfaces, such as may be expected to nourish the toe when its digital vessels are divided, a large dorsal flap is necessary. This must be hinged distally, and for safety is therefore best delayed. A circular flap (Fig. 7), about 8 cm. in diameter and leaving the proximal and distal pedicles of 4 cm. intact, was elevated and then sutured back in position (a bigger and broader flap would have permitted the transfer of two or more toes). For the next two weeks the patient practised maintaining for increasing periods the posture that was to be necessary during the period of attachment. At operation the proximal pedicle was divided and the flap elevated up to its distal pedicle at the base of the big toe. The proximal phalanx of the big toe was divided through the middle of its shaft. The extensor hallucis longus was divided about 10 cm. from its distal attachment. The raw area on the dorsum of the foot was covered with a hand-cut split-skin graft. The scar on the thumb stump and an area of dorsal skin smaller than the foot flap were excised. This stump with its dorsal raw area was then inserted under the foot flap. The extensor hallucis tendon was sutured proximally under the dorsal thumb-skin. The foot flap was sutured to the margins of the thumb defect by interrupted fine serum-proof silk sutures.

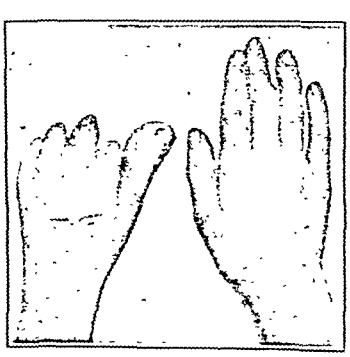

FIG. 4.—Photograph of the two hands eight months after the transfer, but before elongation of the third digit by deepening its webs.

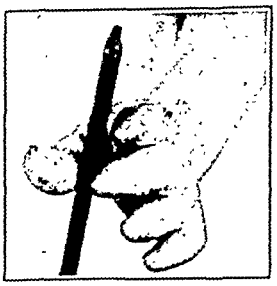

FIG. 5.—The pick-up mechanism present between the third digit and the reconstructed thumb ten months after operation.

Period of Attachment.—Zinc oxide strapping fixation between hand and foot was used. It was not completely effective, and some detachment on the lateral side of the flap occurred. For this reason the period of attachment of the hand to the foot was increased from four to six weeks. The posture caused continuous discomfort and pain for the first three or four days, during which time morphine was often necessary. Subsequently massage and changes in posture controlled most of the discomfort.

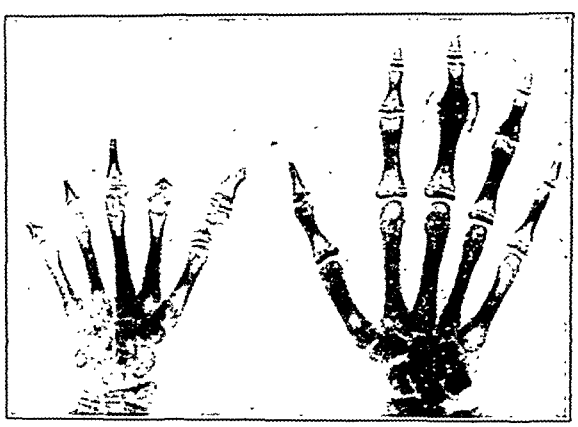

FIG. 6.—Radiograph eight months after the transfer of hallux to base of thumb. The new digit is decalcified compared with the bones of the right hand, but not so much in comparison with the phalangeal stumps on the same side. There is a gap between toe and thumb phalangeal fragments which is to be filled with a bone graft.

Method of Division.—At two weeks the medial digital nerve and vessels of the hallux were divided, and at four weeks the lateral vessels and nerve. It would have been better if the nerves had been divided

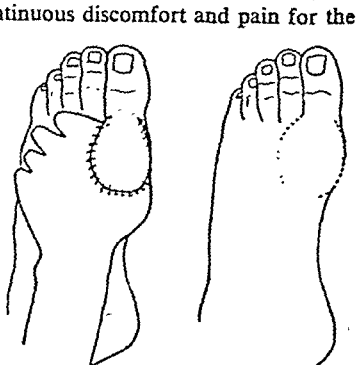

FIG. 7.—Diagram to show proportions of delayed flap (width of flap 8 cm. at widest point). In a subsequent case of complete adactyly at present under treatment a dorsal flap comprising the skin and subcutaneous tissues of the dorsum of the foot from 3 in. (7.5 cm.) proximal to the bases of the toes has been used.

well proximally, as the extra length so obtained would facilitate suture with the thumb digital nerves. At six weeks the remaining volar attachment of the toe and the flexor tendon were divided. The toe stump was covered with a split-skin graft, and some split skin was also spread on the volar defect of the thumb at the level of the attachment. Healing of thumb and foot was complete two weeks later.

Discussion

There are good points and bad points about all current methods of thumb reconstruction or elongation—that is, about pollicization of index, abdominal tubed pedicle plus bone graft, phalangization, and the Gillies "chapeau flap" with bone graft.

A successfully pollicized index, having full mobility and sensation, gives much the best functional result, but the appearance is that of a lobster claw and can be grotesque. Furthermore, in our experience a pollicized index has tended with time to fall back into its original plane flush with the other three digits. For these reasons the method may not appeal for certain cases, particularly young female patients.

An opposition post made of a tube pedicle plus bone graft is rigid unless borne on a mobile metacarpal stump. Its sensation remains poor and is always lacking in stereognosis. It is often of very poor appearance, and increasing mobility of the abdominal skin on the bone graft interferes with its usefulness as a gripping mechanism. It is, nevertheless, the alternative method of choice for adult males when, owing to loss of other digits, pollicization cannot be done.

In partial losses the thumb may have its apparent length increased and its function improved by deepening the first web—that is, the operation called by Bunnell "phalangization." The method is a useful one for cases with substantial remnants of the proximal phalanx.

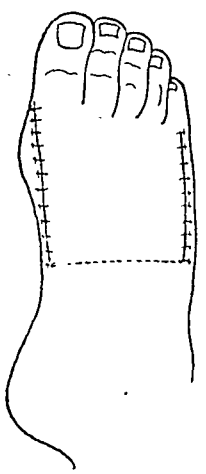

FIG. 8.—Diagram to show delayed dorsal flap used for transfer of five toes (in a case of congenital adactyly at present under treatment). The flap is elevated between two parallel incisions. After an interval of at least two weeks it is divided along the dotted line and elevated again up to the base of the toes. This large flap gives additional security to the pedo-carpal transfer.

The Gillies "chapeau flap," by which an additional 1 in. (2.5 cm.) may be added to a thumb stump, is an alternative method for similar cases. The flap contains most of the skin of the thumb stump and is based distally on the lateral side of the first web—a precarious attachment and one best delayed. When the flap is elevated and displaced distally, a 1-in. bone graft is inserted under it into the phalangeal stump to elongate it. A free skin graft covers the proximal secondary defect. A considerable return of sensation occurs in these stumps, as the repair is by hand skin which has touch corpuscles. This repair is most suitable for adult males, but it makes no attempt at restoration of normal appearance or of interphalangeal movement in the thumb.

It is reasonable to suggest, in view of the limitations of other methods of thumb repair in spite of their value, that the advantages of a hallux–thumb transfer should be given more consideration. This holds particularly for the young, who stand the posture best and who suffer most psychologically from the appearance of a missing digit or an ugly repair. The three cases (of which one is reported here) done in this country are known to have been successful. In the third case (Fig. 8), where all five toes have been transferred to the hand, all the transferred digits are viable (case under treatment at the moment). Previous experience (Gueullette) has probably exaggerated the hazards of the method.

Adactyly.—The method would seem to be of special value for trial in congenital absence of all digits. There are no greater surgical difficulties in transferring five toes than in transferring one—indeed, the dorsal flap for five toes is larger and therefore safer (Fig. 8). The toes with their nails provide the only repair which can give a reasonable match to normal fingers for these difficult and distressing cases.

It is a pleasure to acknowledge our thanks to Sir Harold Gillies, who referred this case to us both with the suggestion that we adopt this method and with much valuable advice on how it could best be done.

Medical Memoranda

Prolapsed Intervertebral Disk After Lumbar Puncture

It would seem from the increasing number of cases of prolapse of the disk with a history of symptoms beginning after lumbar puncture that this hazard of the procedure is more common than is generally accepted. The case described below illustrates the normal sequence of events where damage has occurred to the disk. The condition was finally cured by operation, the laminectomy findings being in support of a possible rupture of the disk by a needle.

CASE REPORT

The patient, a young man aged 22, stated that he had had trouble with his back since November, 1945. At this time he was given spinal analgesia in a military hospital in order to carry out a radical cure of an inguinal hernia. Unfortunately this analgesia was unsuccessful, and, furthermore, while the needle was being inserted he felt a sudden sharp pain down the sides of both legs and they shot out into the extended position quite involuntarily. It is interesting to note that this was followed by a spinal headache for as long as 14 days after the operation. From that time he developed attacks of backache which could be brought on by such minor trauma as jumping down from a lorry.

When seen in the orthopaedic department of the Coventry and Warwickshire Hospital he was suffering from left-sided sciatic pain extending down the outer side of the thigh and into the ankle, which he had had for three months. This was the first attack of sciatica that he had experienced.

On examination he was found to have a slight degree of scoliosis convex to the left, which he stated had been much worse. Forward flexion of the spine was grossly diminished, but lateral flexion was fairly free. There was no evidence of disturbance of sensation or reflexes of the limbs. A radiograph of the lumbar spine showed a narrowing of the disk space between L4 and 5. It was decided to explore the above disk space, and the patient was admitted to hospital.

Laminectomy was carried out by Mr. N. W. Nisbet. The laminae of L4 and 5 on the left side were exposed and the ligamentum subflavum was removed. The dura was found to be pulsating but bulging. On retraction of the dura and the fifth lumbar nerve root medially a very marked protrusion of the intervertebral disk could be seen. This had obviously been producing pressure on the fifth root. Almost immediately the protrusion had been displayed disk material began to exude into the space behind the dura in a manner similar to the exudation of sebaceous material from the minute aperture in a sebaceous cyst. The whole of the disk material was removed in the usual manner.

Post-operative progress was uneventful, the patient's sciatic symptoms being completely relieved, although he complained of some coldness of the left foot. There was no evidence of any sensory disturbance.

There seems to be little doubt that this disk lesion was the direct result of a puncture of the annulus fibrosus of the intervertebral disk. The exudation of nuclear contents through a small aperture supports this causation.

I am indebted to Mr N W Nisbet for permission to publish this case.

Orthopaedic Registrar, Coventry and Warwickshire Hospital

A Case of Human Myiasis

While acting as medical officer in charge of a German P.O.W. working camp in Buckinghamshire I saw a case of human myiasis. As this is unusual in England the case history seems to be worth recording.

CASE REPORT

The patient, a 27-year-old German P.O.W., had had a radical operation for left otitis media in 1940. He said there had always been a purulent discharge from the left ear since, combined with vertigo on thermic irritation. The patient was seen by British and German E.N.T. specialists, who recommended various kinds of treatment, but without any effect on the discharge. The ear was cleaned and iodine powder 1% insufflated regularly.

In the summer of 1947 he had an open-air job at a brick-works in a rural district. Late in September, 1947, he reported sick, complaining of intensified trouble with his left ear, a feeling of pressure, and some pain of two days' duration. There was also a slight discharge of pink-coloured matter.

Examination with the auriscope revealed the following picture. In the external meatus there were some larvae (obviously belonging to a kind of fly) moving in a lively manner. The interior parts—i.e., the former tympanic cavity —were filled completely by a moving mass. It was a solid block of larvae lying parallel and swimming in a pink serous fluid; the heads of the maggots were directed to the inner ear and only the bigger tails were visible.

As I knew the "normal" state of this ear very well and as a removal of all the larvae by means of forceps seemed to be impossible, I tried very cautious rinsing with normal saline. At first the larvae were removed quite easily and without any untoward effect; but it soon became clear that a number were still present in small sinuses stretching into the posterior wall of the tympanic cavity and of the external meatus. As they were very tightly packed and the entrances of the sinuses were rather narrow, the maggots had to be removed by forceps one by one. A final counting revealed that there had been 57 larvae within his ear.

Examination after complete clearance showed the ear to be quite clean, without any trace of pus. The sinuses into the posterior wall did not exist in the "normal" state; they were to be regarded as caused by the parasites. Close observation during the next few days showed that pus had formed again and that the sinuses had closed quickly. The further course of the case was uneventful.

COMMENT

Unfortunately it was impossible to save the larvae for metamorphosis into flies, so it was rather difficult to decide on the species. Dr. J. S. K. Boyd, of the Wellcome Laboratories of Tropical Medicine, stated that they belonged to "one of the species of the genus *Lucilia*, probably *L. sericata* or *L. caesar*."

The genus *Lucilia* (blow-flies) is the one most often encountered in human myiasis in Europe; but cases are very rare there compared with tropical countries. Myiasis due to larvae of the blow-flies is always superficial only. Sometimes the larvae are primary parasites—i.e., they attack healthy tissues. Mostly, however, the eggs are deposited on necrotic and putrescent matter (secondary parasitism), as in this case. Commonly the fly deposits its eggs in some quantity and the larvae get rapidly to work. In hot climates (the summer of 1947 was very hot) it takes 16 to 24 hours for the eggs to hatch; after four to seven days the larvae are fully grown and proceed to form the chrysalis.

Of practical importance is the fact that some of these parasites live on necrotic tissues only, while others, after starting from necrotic matter, secondarily attack living healthy tissues as well. *L. caesar* belongs to the former group, whereas *L. sericata* attacks living surroundings (the sinuses in the present case); both are therefore apt to cause very serious complications, such as perforation of the epitympanic bone and secondary infection of the meningeal spaces.

Contrary to surgical experience, the cleansing effect of the allantoin formed by the larvae was not lasting: a few days after removal of the maggots pus was present as before.

I am obliged to Drs. Lucas and Sherris, of the Central Pathology Laboratory, E.M.S., Stoke Mandeville Hospital, Bucks, for their kind help. May this short note be a token of my gratitude to all British colleagues, who, through 16 months, gave me so much help and assistance and showed that medicine does not know national barriers.

HELLMUT W. F. BRAUNECK.
Mayen, Germany.

A pamphlet by Marion E. A. Williams entitled *Focus on the Disabled* has recently been published by Michael Works, Ltd. The founders of this company were "a small group of people convinced that disabled persons, previously regarded as unemployable, could be trained and employed in producing useful goods which could be offered in the open commercial markets at normal prices." Michael Works, Ltd., began work in 1946, small articles of woodware and simple occasional furniture being produced. The supervising staff consisted of managing director, secretary, medical officer, physiotherapist, industrial psychologist, and foreman. Close co-operation was maintained with the local resettlement officer of the Ministry of Labour. The disabilities of the workers employed in the factory varied from spastic conditions to neuroses. It was soon found that the workers could be trained to produce articles with a standard of quality as good as anything existing on the market, and the company has been successful in tendering for such work as the repair of school desks for the L.C.C. and for making new furniture for old people's homes. Any falling off in the working capacity of an employee is the signal for immediate consultation between the medical officer, managing director, and foreman. "In this way the medical knowledge available has been applied in practice at the earliest possible moment, with great saving in ill-health and absenteeism."

Reviews

DOCTORS' DRUGS

The British Pharmaceutical Codex, 1949. (Pp. 1,562. £3 3s. Inland postage 1s.) London: The Pharmaceutical Press. 1949.

Early in the century medical treatment consisted largely in the elaborate prescription of medicines elegantly flavoured, meticulously bottled, and exquisitely labelled. If 80% of these bottles had been poured into the sea the fishes only would have suffered. In that age, therefore, a knowledge of the action and uses of drugs was of secondary importance. It is very different nowadays. Medical men, often of modest attainments, find themselves—Jovelike—hurling terrifying therapeutic thunderbolts, and it now behoves them to know more about these alarming weapons of their trade than can be gleaned from the pharmaceutical advertisements which litter their breakfast tables.

In the *British Pharmaceutical Codex* of 1949 can be found all—and a good deal more—information than the doctor can ever expect to master about the preparations, doses, actions, and uses of drugs. There are in addition sections on serums and vaccines, preparations of human blood, and surgical sutures; and a formulary of prescriptions—hardly a pocket prescriber, as it involves over 300 pages—some of which have a faintly nostalgic nineteenth-century flavour about them but which must provide for every possible therapeutic contingency.

If only for the descriptive paragraphs on the action and uses of drugs this work should appeal to medical men as well as to pharmacists. These descriptions are masterpieces of concise, accurate, and comprehensive information, and on occasion do not hesitate to point out the worthlessness of the drug under discussion. It is perhaps prophetic that the sections devoted to the preparation of human blood and to surgical ligatures contain no Latin names: it would have been a nice exercise to translate "Concentrated Human Red Blood Corpuscles" into the more humane letters.

Although over 300 drugs have been deleted from this edition of the *Codex*, yet the pruning knife might with advantage have been used even more drastically. If the volume has a fault it lies in its perpetuating some drugs and prescriptions which have long since had their day and been found wanting. The work is otherwise an invaluable and handsome encyclopaedia of pharmaceutical, pharmacological, and therapeutic knowledge which is a monument to the industry and erudition of the committee of the Pharmaceutical Society which has been responsible for its publication.

D. M. DUNLOP.

ILLUSTRATIONS OF MARROW PATHOLOGY

An Atlas of Bone-Marrow Pathology. By M. C. G. Israëls, M.Sc., M.R.C.P. Illustrations by D. Davison. (Pp. 79: 12 coloured plates. £1 10s.) London: William Heinemann Medical Books. 1948.

This book contains about 50 large pages of text and 12 plates, all printed on art paper and well bound. The text is excellent. It begins with a concise account of the nomenclature of the blood cells and their development. Brief details of technique are given, and the morphology of the marrow cells is described. There follow short descriptions of the blood and bone marrow in health and disease.

The book has already received the compliment of being accepted as the standard English manual of haematological nomenclature. It must nevertheless be confessed that the plates are disappointing. They are greatly inferior to productions in other countries—for example, Schulten's *Sternalpunktion*, or Blackfan, Diamond, and Leister's *Atlas of the Blood in Children*. The delineation of blood cells is as specialized an art as the painting of miniatures, and artists who are otherwise excellent often fail at it. Haematological nomenclature is so controversial a subject at the present time, and European opinion has been so unanimously opposed to the new terminology for the red cells and their precursors recently introduced by Osgood and others in the U.S.A., that it is unfortunate that Israël's fine text and diagrams are so inadequately supported by the plates.

THE AETIOLOGY OF MONGOLISM

Mongolism (Peristatic Amentia). By M. Engler, M.D. (Pp. 208; 28 illustrations. £1 1s.) Bristol: John Wright and Sons. 1949.

In his preface to this monograph Dr. Engler makes a two-fold claim, and it is upon the validity of this claim that his book must be judged. He writes: "This monograph is intended both as a summary of everything that has ever been published on the subject of mongolian idiocy and as an attempt to show that there can only be *one* explanation of its cause." The nature of this unitary cause he states to be "a congenital degeneration or malformation produced by the implantation of a normal ovum, not affected by any heredity taint, in a pathological, i.e., diseased, uterine mucosa, which is unable to supply the embryo with sufficient nourishment. . . . This damage to the mucosa . . . and *this alone*, is the basic cause of mongolian idiocy."

No other form of degenerative abnormality has received more attention than mongolism, and Dr. Engler has evidently read widely the literature of the subject and the large number of explanations of causation which have been put forward. These he reviews systematically, but, in spite of all the arguments which he adduces in support of his own, it is doubtful if his positive assertion quoted above will command general acceptance. There are many considerations which militate against this theory as a complete explanation, depending as it does on so many assumptions. Until it can be proved that a diseased uterine mucosa always precedes and predetermines the birth of a mongol but not that of other forms of congenital amentia, the argument must be considered as belonging to that type of faulty reasoning known to logicians as *Inductio per simplicem enumerationem*.

On the other hand, the extraordinary uniformity in physical and temperamental attributes shown by mongols, whatever their nationality, places the type in a clearly defined class distinct from all other forms of degenerative amentia. Another point which has some significance in this connexion is the well-attested class-selectivity, for mongolism occurs with far greater frequency amongst the professional classes and highly intelligent thoughtful craftsmen than in the unskilled labourer class. It cannot be argued that this disparity is due solely to a differential infant mortality rate which carries off all the mongolian infants at birth or before their condition can be recognized.

So convinced is Dr. Engler of the validity of his pathological explanation that he proposes it should be implicitly enshrined in the term "Peristatic Amentia," which he would substitute for that of "Mongolism." But this

proposal to change from a term which for 80 years has admirably described the condition and has been universally accepted is not likely to recommend itself to many physicians, whose verdict on the theory which Dr. Engler asserts so positively will be "not proven."

G. A. AUDEN.

ANATOMY OF THE NERVOUS SYSTEM

Neurological Anatomy in Relation to Clinical Medicine. By A. Brodal. (Pp. 496; illustrated. £2 2s.) Oxford: The Clarendon Press. 1948.

Functional Neuro-Anatomy. By A. R. Buchanan, M.D. (Pp. 242; 199 figures. £1 12s. 6d.) London: Henry Kimpton.

Dr. Brodal's book will be indispensable to students of clinical neurology and of the greatest value to those already in practice, for it is an authoritative neuro-anatomical textbook that emphasizes the clinical applications of the subject. It is a translation of *Nevro-Anatomi*, which was first published in 1943 in Norwegian and was so successful that the author was persuaded to produce an English translation.

Dr. Brodal's approach to the subject is clearly the result of much careful thought. Although he is a neuro-anatomist of wide reputation he does not allow anatomical details to obtrude excessively to the exclusion of physiological and clinical observations, and he has managed to avoid including anatomical minutiae which, though of interest, are irrelevant to the purpose of the book. Despite this, carefully selected references to original papers will enable those interested to acquire as much detailed anatomical knowledge as is available.

This book is not generally suitable for preclinical medical students. For one thing, it is too long. Secondly, it is in places difficult to read quickly, for the author has taken particular care when discussing controversial points to make no statements or assertions without giving the evidence upon which they are based. Dr. Buchanan's book, however, is intended primarily for the student. The author has set out to present the essential material in as few pages as are compatible with an understanding of the subject. In this he has succeeded, and his concentration on the functional aspect of neuro-anatomy will not only maintain the student's interest but also emphasize the importance of a sound knowledge of the anatomy of the nervous system in future clinical studies.

While most of the information contained in this book is an expression of current knowledge and opinion, there is a notable exception. The chapter on the rhinencephalon expresses views which are now known to be outdated. For instance, the hippocampus is still described as a cortical olfactory centre, whereas the work of Le Gros Clark and others has shown conclusively that there is no evidence for such a conception. It is possible that the manuscript of this chapter was completed some time before publication, and it is to be hoped that this section will be revised in the next edition. The references to the literature have intentionally been kept to a minimum, but those included have been judiciously selected from recent publications.

G. WEDDELL.

PSYCHIATRY: A FRESH VIEWPOINT

Human Personality and its Minor Disorders. By William Harrowes, M.D., F.R.S.Ed. (Pp. 260. 15s.) Edinburgh: E. and S. Livingstone. 1949.

This book is an exposition of the psychiatric concepts formulated by Professor Adolf Meyer, who made a great contribution to psychiatric thought in America, and whose teaching has come to this country with many British psychiatrists who studied under him at Johns Hopkins. It is refreshing to encounter a viewpoint detached from the psycho-analytical theory which pervades most psychiatric literature at the present time. Dr. Harrowes has achieved this, and his book will therefore not please the confirmed analyst, but to any reader with an open mind it will be intriguing and will provide a pattern into which clinical experience can be fitted and from which a psychiatric philosophy can be developed.

The author maintains there is nowadays too great a tendency to make a neurosis out of the ordinary ups and downs of everyday life and to imagine that every worried man is in an anxiety state. He develops the thesis that every personality is the resultant of mental and physical forces, and that by using these forces it adapts the environment to itself or itself to the environment.

To approach his patient correctly the psychiatrist must make an assessment of his own potentialities, attitudes, and emotional habits and those of a few others, who must be chosen as being different from himself. From this self-analysis and its comparison with the observations made on others a degree of insight can be attained and a scale formulated against which clinical observations can be assessed. This process is analogous in its aim to the training analysis of the more conventional analytical schools.

The use of Meyer's "Life Chart" is explained in detail. It is a method for recording under several headings the main episodes in the history and the bodily and emotional lives of the subject. It provides a simple graphic way of setting out the main points in a case history. Readers not conversant with the writings of Adolf Meyer may find the phraseology a little difficult and the introduction of the "ergasias" confusing and even superfluous, but a bibliography of Meyer's works will enable the interested student to follow up his reading.

It is unfortunate that only ten pages of the book are allotted to treatment, and in future editions a more detailed exposition of method would relieve the disappointment the reader feels after the detailed descriptive and diagnostic expositions. The work can be recommended as suggesting an interesting line of thought to all serious students of psychiatry.

WILLIAM MOODIE.

A GUIDE TO SPONDYLITIS

Ankylosing Spondylitis. Part 1 by F. Hernaman-Johnson, M.D., D.M.R.E. Part 2 by W. Alexander Law, O.B.E., F.R.C.S. (Pp. 200; illustrated. £1 5s.) London: Butterworth and Co. 1949.

Before the first world war ankylosing spondylitis was regarded as a rare disease for which there was no effective treatment. How far its apparently greater frequency now is due to war conditions and how far to improvement in diagnosis is difficult to say, but it is still a reproach that it is often not recognized until three or four years after the first symptoms appear, when the patient is crippled and the time for effective treatment has passed. This book may therefore be strongly recommended as a guide to the recognition and management of the disease, especially to doctors in general practice, as well as on its merits, which are considerable.

Dr. Hernaman-Johnson had an exceptionally wide experience of the disease and the methods of treatment, and it is a matter of great regret that he did not live to see the appearance of the book. Written in a clear and attractive style and with excellent illustrations, it describes the condition from its earliest stage and discusses fully the

pasteurization is carried out on a large scale in the towns and only to a small extent in the country districts. The annual report for 1948 of the medical officer of health of Manchester, typical of reports from other large centres, contains some interesting figures. In the case of pasteurized and heat-treated milk 92% of samples passed bacteriological and chemical tests satisfactorily, and all samples were negative for tubercle bacilli. Of ungraded milks 66% of samples were unsatisfactory, and 15% were positive for tubercle bacilli. The bad effect of the bulking of milk is illustrated by the fact that samples taken from tanker lorries coming into the city were all unsatisfactory bacteriologically, and 86% were found to contain tubercle bacilli on biological examination. This shows yet once more that housewives who cannot obtain pasteurized milk would be well advised to boil the family milk. The problem of providing the population with safe, clean milk from disease-free herds is by no means solved, but the report of the Joint Committee points the way to some much-needed improvements.

VISCERAL ACTINOMYCOSIS

In the Bradshaw Lecture, which we publish elsewhere in this issue, Mr. V. Zachary Cope discusses the subject of visceral actinomycosis. Among advances in our knowledge of this disease not the least concerns the origin of the infection, and authors who have not divested their minds of some of the more fanciful ideas entertained on this subject in the past may well take note of Mr. Cope's categorical assertion that this infection is autogenous. That grass or straw could be the source of a micro-organism of fastidious growth requirements which include anaerobiosis has never been credible, and actinomycetes found in such material are now recognized as distinct species. There remains one other hypothesis —that the disease can be acquired from cattle. The actinomyces which produces jaw lesions in these animals closely resembles the human organism in most of its characters, but according to Erikson[1] differs from it both in fermentation reactions and in antigenic constitution. Erikson's observations suggest that bovine and human actinomycetes are distinct, and, though it seems very unlikely that the human disease is commonly acquired from cattle, it cannot be taken as proved that this never occurs.

Among problems connected with this disease is one of nomenclature. The animal organism should clearly be called *A. bovis*, and there is a preference for calling the human *A. israeli*, though *A. hominis* has been suggested and is probably justified in its implication that the species found in man is distinct and peculiar to him. The study of these fungi would be simplified if they were pathogenic for laboratory animals, but attempts to reproduce the disease in this way, even when as persevering and varied as those of Rosebury and his colleagues,[2] have had only minor and inconstant results. The evidence that the usual source of the infection is the patient's own mouth, though in a sense circumstantial, is overwhelming. The close association with trauma in this region embraces not only dental extraction but compound fracture of the mandible, of which actinomycotic infection may be a consequence. Several workers have overcome the technical difficulties of demonstrating that actinomyces may exist in the gums of persons not suffering from the disease. It is significant that Rosebury[3] obtained the material on which his extensive studies of this organism are based mainly from a department of dental surgery.

The second problem connected with this disease is diagnosis, more particularly in its visceral forms. There is no disease of which the nature can be so obvious at necropsy when its features during life have been so obscure, and the physician or surgeon of long experience who has never seen an unexpected honeycomb abscess of the liver in the post-mortem room is fortunate. Disease in the appendicular region has the most insidious onset and is most likely to be unsuspected, since its only sign for many weeks may be the failure of a sinus following appendicectomy to heal. Responsibility in this matter rests on both surgeon and bacteriologist. Of the former Mr. Cope writes: "I purposely repeat that a final and important cause of failure to diagnose actinomycosis is that the disease may not be on the mental list of possible diagnoses which the observer goes through as a routine." The duty of the bacteriologist is similar: he must have this infection constantly in mind when examining pus from the neck, thorax, or right lower quadrant of the abdomen, particularly if it contains no other obvious pathogen. He must begin by using the naked eye in a search for granules, if he has been fortunate enough to be sent pus in a tube and not a mere swab. Finally, he must not be content with aerobic culture and what he may find in it. An actinomycotic lesion which has been draining is often secondarily infected; sometimes it contains other bacteria even in its earliest stages.

Mr. Cope's remarks about treatment are more encouraging than anything which could have been written more than five years ago. As was observed in these columns last year,[4] there has been a two-stage improvement in the treatment of this as of many bacterial infections. Sulphonamides, particularly sulphadiazine, have a marked suppressive effect: that of penicillin is clearly more potent and sometimes actually curative. The findings of Holm[5] on the effects of particle size on

1 *Spec. Rep. Ser. med. Res. Coun., Lond.*, No. 240, 1940, London: H.M.S.O.
2 *J. infect. Dis.*, 1944, 74, 131.
3 *Bact. Rev.*, 1944, 8, 189.
4 *British Medical Journal*, 1948, 2, 830.
5 *Acta path. microbiol. scand.*, 1948, 25, 376.
6 *Arch. Surg., Chicago*, 1948, 57, 202.

the results of penicillin sensitivity tests suggest that the intact colony or "granule" in the body may be more resistant than its constituent elements, merely because its size and compactness prevent full penetration. Hence it is probably advisable to use fairly large doses of penicillin from the outset, and it is certainly necessary to continue the treatment for a longer time than in most other conditions. All writers on this subject are agreed that the prognosis is now much improved. Campbell and Bradford[5] describe six cases exemplifying this change. Three of appendicular origin, occurring in pre-penicillin days and treated respectively with "promin," sulphonamides, and *x* rays, were all fatal. One other fatal case was a man aged 84 in whom surgery was inadvisable: the remaining two—one thoracic, the other involving the liver—owed their recovery to penicillin combined with sulphonamides and surgery respectively. In the case in which surgery was successful a spherical liver abscess was wholly excised—an unusual surgical feat. The sensitivity of different strains of actinomyces to penicillin has been shown to vary, and for those found more resistant streptomycin is now a possible alternative.

NECESSARY ADJUSTMENT

Deciding that the Ministry's letter[1] on the remuneration of general practitioners should not be taken as closing the matter, the General Medical Services Committee resolved at its special meeting on December 1 to send a deputation to the Ministry in order to discuss certain figures and to seek an assurance that the Government intends to fulfil the Spens Committee's recommendations—as it has promised to do. Throughout these negotiations the Ministry has carefully avoided stating its views in precise terms about what has come to be called the betterment factor—that is, the figure by which the total pre-war income of general practitioners must be multiplied to translate it into the present value of money. The remuneration that general practitioners receive at present has never been anything but provisional. What is agreed between the Ministry and the profession is the total amount that general practitioners ought to have earned in 1939—£31.24 million. This is an estimate based on the Spens Report. The Spens Committee also referred to the "necessary adjustment" that must be made to translate its recommendations into present-day terms. Though the Government has accepted the Spens Report, it has never seriously discussed this important proviso in the Report. While the B.M.A. has taken pains to find out by how much the cost of living has increased, and obtained an expert opinion on it, the Ministry has not committed itself on the issue.

After admitting[2] that the estimates of payments to general practitioners for the year 1949–50 fall short of the Ministry's own calculations of the profession's claim by some £4.7 million, the Ministry argues that the claim "compares . . . with the sum of nearly £49 million already being provided." Apparently the comparison seems to the Ministry to be a close one; to those who receive the money it seems more distant. The gap is wider still, in the view of the G.M.S. Committee, when the B.M.A.'s figures are compared with the Ministry's, and the accuracy of some of the Ministry's figures will be challenged when the deputation goes to the Ministry. The Minister's view is said to rest "on the sheer merits of the case." Merits are more difficult to compute than figures, and the profession is unlikely to be satisfied with an attempt to refute its case by means of less rigorous arguments than its representatives used when preparing it.

All would agree with the Minister that the country's economic state precludes "unjustified raising of remuneration." But in the first place the general practitioner's claim has been justified by a careful analysis of the figures, and in particular of the betterment factor, whereas the Ministry's attempted refutation has not. And, secondly, it is misleading to speak of raising remuneration when what is now being paid was never agreed except provisionally. The profession will be gravely disturbed if the G.M.S. Committee has not received satisfactory assurances before its next meeting early in the New Year.

YELLOW FEVER IN AFRICA

Knowledge of the distribution of yellow fever in Africa was not very different 20 years ago from what it had been 200 years earlier. Yellow fever was, it was thought, confined to the countries bordering on the west coast of Africa from the Senegal to the Cameroons, with possibly an extension to the mouth of the Congo. After the discovery that the infection could be transmitted to rhesus monkeys and then to mice it became possible to devise protection tests; these indicated the presence of virucidal bodies in the sera of those who had once had yellow fever, and, since the immunity to one attack of yellow fever is lifelong, it was not difficult to determine the extent of the immunity in different age groups. Even before 1939 the mouse-protection test had disclosed that there were children with immune bodies to yellow fever in Uganda and in the Anglo-Egyptian Sudan as far east as the Blue Nile. In the absence of proved clinical cases, however, it is not surprising that colonial Governments were loath to conclude that yellow fever was endemic in their particular areas. But the large outbreak of yellow fever in 1940 in the Nuba Mountains removed the last possible excuse for disregarding the significance of the mouse-protection test. Since then the area in Africa where yellow fever has been found to be present has slowly but surely extended. Positive

[1] *British Medical Journal Supplement*, 1949, 2, 218.

[1] *Ann. trop. Med. Parasit.*, 1949, 43, 182.

mouse-protection tests in the south-eastern part of the Sudan were soon followed by recognition of a clinical case. The infection was found in Eritrea, Somalia, and Kenya, and to the south the Balovale district of Northern Rhodesia also was shown to be an endemic area.

Recent surveys by Smithburn and his colleagues,[1] carried out between 1944 and 1948, indicate that the limits of the endemic yellow-fever area have not yet been reached. In various parts of Kenya, especially in the Langata forest, tests on children's sera were positive. In Tanganyika immune children under 15 were discovered at Tanga, Lindi, and Moshi. At Lilongwe, among other infected areas in Nyasaland, 7 of 37 children under 15 were positive. In Northern Rhodesia positive results were obtained in all areas investigated, and there is little doubt that along the Zambesi infection is common, for of 789 children and 2,266 adults examined no less than 229 were positive. This is a higher rate than for any other country in the eastern half of Africa. Although Swaziland, so far as it has been examined, has given negative results, Bechuanaland is infected: at Mohembo 3 of 24 tests on children were positive. At Massanga in Mozambique positive results were obtained in tests on adults and children. Since the endemic yellow-fever zone already extends at least as far south as Tsau, in Bechuanaland, just south of the twentieth parallel of latitude, the Government of the Union of South Africa now has certain important sanitary problems to face. Every year many thousands of African labourers migrate, mostly on foot, to the mines on the Rand from the Rhodesias, Nyasaland, Mozambique, and Bechuanaland. It is possible that they may become the agents responsible for the spread of yellow fever over South Africa. Two possible courses are open to the sanitary authorities in the Union—the immunization of all labourers before they reach the Union, and the eradication of all yellow-fever vectors, especially *Aëdes aegypti*, within the borders of South Africa. Either course will be expensive and require careful organization.

Results of recent surveys elsewhere are also of interest. For some time past the Egyptian authorities have been seriously exercised over the importation of yellow fever: positive results have been obtained in tests on adults and children in Nuba, Luxor, Safaga, and Kosseir. Plainly further tests are necessary, but meanwhile it is obvious that the yellow-fever zone in Africa must be adjusted in accordance with the information now available.

PENICILLIN IN PURULENT PACHYMENINGITIS

The use of penicillin as an ancillary to the surgical treatment of intracranial infection has improved the prognosis in many cases which would otherwise almost certainly have ended fatally. Sir Hugh Cairns, Professor Dorothy Russell, and Dr. F. Schiller[1] have reviewed the results of the treatment of purulent pachymeningitis over a 20-year period, both before and after the advent of penicillin. Of 23 patients who received no penicillin or who were treated in the early period after its discovery when adequate supplies were not available, all died; while seven patients recovered out of 10 treated adequately with penicillin combined with surgery.

Purulent pachymeningitis, a condition "characterized by a film of pus of variable thickness in the subdural space spreading over part or whole of one or both cerebral hemispheres," is usually secondary to spreading osteomyelitis of the skull or facial bones, which itself is one of the rarer but most serious complications of infection of the accessory nasal sinuses or middle ear. The condition is recognized clinically by the onset of widespread paralysis due to cortical damage, associated with a rise in intracranial pressure, and before the advent of penicillin usually ended fatally within two weeks. Extradural abscess and thrombosis or thrombophlebitis of the venous sinuses and cerebral veins are frequent complications, and cerebral abscess may occur later. A remarkable finding in Cairns's series was that in the 27 cases in which bacteriological reports were available the causal organisms in 25 were streptococci of anaerobic or non-haemolytic types. This is contrasted with the findings in 22 cases of osteomyelitis of the skull not complicated by purulent pachymeningitis: in 14 of these the infection was due to staphylococci.

The treatment adopted by the authors was to administer penicillin by the systemic, subdural, and subarachnoid routes and to remove large collections of pus as they arose by minor surgical operations. Intramuscular injections of penicillin in doses of 100,000 units three-hourly were begun immediately on diagnosis, and were continued for at least eight weeks in all cases complicated by osteomyelitis, thrombophlebitis, or loculation of pus in the subdural space. Although penicillin was shown to diffuse readily into the subdural space, experience with two cases suggested the advisability of raising the local concentration by means of rubber catheters inserted through burr-holes. As much of a solution containing 500 units per millilitre as the space would hold was instilled at three-hourly intervals; this also had a mechanical action in preventing formation of local subdural abscesses. Subarachnoid or intraventricular penicillin was given if leptomeningitis was present or, as a prophylactic measure, if exploratory operations through an infected field were necessary; for the latter purpose injection of a single dose of 10,000–15,000 units into the ventricle was recommended. With this method of treatment the removal of large areas of infected bone was unnecessary, surgical treatment being confined to removal of sequestra or persistent foci of infection. Subdural abscess developed in seven of the 10 cases adequately treated with penicillin, and the authors stress the importance of early recognition and treatment of this complication. The commonest site was the posterior part of the falx cerebri and adjacent part of the tentorium, and on *x*-ray examination after the injection of "thorotrast" into the abscess cavity a characteristic shadow was seen, which facilitated the differential diagnosis from cerebral abscess. Daily instillation of 200,000 units of penicillin in 2 ml. through an indwelling catheter for at least five days was found to be necessary to secure healing.

The results of treatment in the six survivors who were followed for periods of from six months to five years were very satisfactory: functional recovery was complete in five, including four with aphasia. The authors stress that good

[1] *J. Neurol. Neurosurg. Psychiat.*, 1948, **11**, 143.
[2] Turner, A. L., and Reynolds, F. E., *Intracranial Pyogenic Diseases*, 1931, Edinburgh.

results can be expected only if treatment is begun in the early stages, before subdural loculation has occurred; but, since purulent pachymeningitis most commonly follows operations (even simple antrum puncture[2]) for chronic pansinusitis or mastoiditis, the authors suggest that in all such cases prophylactic penicillin should be given in order to prevent its development. The routine use of prophylactic penicillin in otorhinological practice will undoubtedly reduce the incidence of serious intracranial complications, which may follow any operative procedure however skilfully performed.

STRESS, FIBRINOLYSIS, AND ATHEROMA

Atherosclerosis is widely regarded as a stress disease which contributes to the premature ageing of arteries, randomly curtailing intellectual or physical capacity and commonly shortening the days of man. Converging lines of investigation—Duguid's on the fibrinous origin of atherosclerosis,[1-3] Macfarlane's on fibrinolysin activity of the blood during life,[4-7] and Mole's on fibrinolysin and the fluidity of the blood post mortem[8]—open up a new approach to this aetiological problem. There is the further promise of additional valuable information from the concept of "adaptation diseases" developed by Selye,[9-10] from his analyses of the body's defences against stress and strain. Comment on Selye's work has already been made in leading articles in this *Journal*.[11]

As a result of his histological study of coronary arteries and aortas Duguid concludes that mural thrombi on vascular endothelium can be transformed, by the interplay of fibrous organization, fatty change, and acquisition of fresh endothelial lining, into typical atherosclerotic nodules. The frequency with which this transformation occurs is not yet known, but the opportunities are plentiful: Duguid found that mural thrombi, either fibrinous or mixed, are common, and that at least some of them develop into atherosclerotic thickenings. He makes the deduction that these thickenings may depend not only on factors which act on the tissues of the vessel wall but also on those which govern fibrin formation in the circulating blood. In their investigation of the latter factors Macfarlane and his associates found that fibrinolysis activation in the blood during life may be the initial result of a variety of stimuli having in common the exposure of body or mind to unusual stress. This activation in normal blood may be a component of the initial shock phase of Selye's alarm reaction. Mole points out that during life there is a continual production of fibrinogen by the liver, that this must involve a continual removal from the blood stream, and that normally some deposition of fibrin would be expected. Having investigated the relation between fibrinolysin and the fluidity of the blood at necropsies, he considers that fibrinolysin is most probably produced by the vascular endothelium and that this may be the natural physiological means of preventing undue mural deposition of fibrin in health. Failure of fibrinolysis will promote the deposition of mural thrombi, which may form the initial lesion in atherosclerosis. Such failure, for example, occurs in infection and cachexia, conditions which favour thrombosis. Mole concludes that there is an obvious connexion between the presumptive failure of fibrinolysin to prevent mural thrombi and the view that atherosclerosis is a failure in the body's defence against stress and strain. The tentative concept which emerges from these investigations has wide implications—that failure of fibrinolysis is related to atherosclerosis and that both processes are threads in the variegated pattern of the body's responses to stress.

RESPIRATORY DEPRESSION AND ATELECTASIS

One of the more important of the several factors concerned in the development of post-operative pulmonary atelectasis is the diminution of respiratory movements during the immediate post-operative period.[1] Some interesting information about depressed respirations in the absence of complicating factors has been obtained by Swank and Smedal,[2] who studied the pulmonary changes during deep sleep in 350 patients undergoing sodium amytal narcosis for the treatment of combat neurosis. It was found that respirations were shallow throughout the period of deep sleep, the tidal air being reduced from 550–750 c.cm. to 150–300 c.cm and the diaphragmatic excursion (observed by fluoroscopy) from 3 cm. to 1 cm. Periods of apnoea were noted during the induction phase, but the respiratory rate returned to normal as sleep deepened. Cyanosis was present almost invariably and responded to inhalation of pure oxygen. The depth of respiration increased on breathing 100% oxygen, and no further increase was obtained by the introduction of 5% carbon dioxide. Twenty-eight patients were examined radiologically before, during, and after the three days of narcosis. Ten of these showed changes which were considered to be the usual concomitants of deep sleep—namely, symmetrical elevation of the diaphragm and narrowing of the thoracic interspaces. In addition, cloudy patches appeared in the lung fields of 18 patients, together with greater elevation of the diaphragm and narrowing of the interspaces on the same side. These changes were regarded as sufficient evidence of pulmonary atelectasis. In four patients the atelectasis persisted for two to six days after the end of the treatment, and all these patients had fever and tachypnoea. The authors considered that the focal changes in the lungs were due to lobular or segmental atelectasis, and that the fever was secondary to the lung changes.

The occurrence of lobular atelectasis has often been disputed, since it is known that in normal conditions interalveolar gaseous interchange takes place via the pores of Kohn.[3] It has been shown, however, that when respirations are sufficiently depressed this gaseous interchange is absent.[4] Thus shallow breathing can contribute to the development of atelectasis in several ways: the bronchi.

narrowed in the position of expiration, are easily obstructed by mucus; the upward thrust from bronchial peristalsis is minimized; and the occurrence of lobular collapse brings about a diminution of the effective tidal air and precipitates segmental collapse. An additional factor is that anoxia produces an increase in lymph flow and excessive bronchial secretions.[5] The knowledge that patchy pulmonary atelectasis arises from depression of breathing is important, for a number of clinical states are characterized by shallow breathing. Lobular atelectasis may well be the precursor not only of post-operative chest complications but also of the bronchopneumonia which occurs in old and debilitated patients and in those in coma due to any cause. The value of active or passive breathing exercises in the treatment of such patients cannot be too strongly emphasized.

LIVER PATHOLOGY AND FUNCTION TESTS

Although modern liver function tests have helped clinicians in both diagnosis and prognosis, their relation to hepatic histology has never been exactly determined. This is largely due to the difficulty of collecting a sufficient number of cases in which biochemical tests and histological examinations are performed at the same time. The possibility of inquiring into the relationship has now existed for some years, since liver puncture has become a common diagnostic procedure, and a number of workers have reported the results of their investigations.[1-2] These studies have disclosed a limited correlation in acute hepatitis between the extent of hepatic damage and the serum bilirubin and albumin levels, and also a relationship between thymol turbidity and regeneration combined with periportal infiltration. However, no conclusion which applies to all types of liver disease was reached, and many of the tests, such as the hippuric-acid test, could not be correlated with any definite histological feature.

More definite results have recently been reported by Franklin and Popper and their colleagues,[3] who carried out liver function tests and liver biopsy or puncture in 135 cases. The histological results were expressed in a numerical form, and the correlation between a number of definite histological features and liver function tests was determined by appropriate statistical methods. The most important of the significant correlations was that of diffuse liver cell damage with the albumin/globulin ratio, the cephalin-cholesterol flocculation, the thymol turbidity, and bromsulphthalein retention (the last only in non-jaundiced patients). Other correlations to be established were liver-cell regeneration with increased thymol turbidity, distorted reconstruction of the lobular pattern with cephalin-cholesterol flocculation, thymol turbidity and erythrocyte sedimentation rate, and Kupffer cell activity with serum bilirubin and the albumin/globulin ratio. No relationship was found between parenchymal damage and total serum protein, total cholesterol, the cholesterol ester ratio, urinary urobilinogen, stool urobilinogen, alkaline phosphatase in general (and markedly elevated alkaline phosphatase specifically), non-protein nitrogen, and the erythrocyte sedimentation rate. The mainly negative results with the serum alkaline phosphatase test are surprising, since this test can undoubtedly be correlated with biliary obstruction. It would appear that some of the functional changes in the liver cell in biliary obstruction cannot be shown histologically—a fact which demonstrates an important distinction between biochemical and histological investigations. These results give theoretical backing to a number of tests, such as the flocculation tests, which have usually been labelled "empirical." It has long been obvious from clinical studies that they were closely related to liver disease, but they can now be interpreted with more confidence against a background of liver histology. It is to be hoped that further similar studies will be undertaken for the purpose of correlating biochemical with clinical and pathological findings.

HOME FEEDING OF INVALIDS

The Invalid Kitchens of London is one of the few organizations which work to keep people well so that they do not need to be admitted to hospital. Started some years before the war, this service, which is still supported by voluntary contributions, prepares suitable diets for patients who would otherwise have difficulty in obtaining them. Kitchens (17 before the war) scattered over the Metropolitan area provide a six-day service of midday meals but only to patients whose doctor gives them a prescription. Each kitchen is managed by an experienced cook and all are regularly supervised by an expert dietitian. Meals are served at the kitchen to individuals who are ambulant, but some can be sent out to patients who are confined to house or bed. Extension of the latter service is difficult, because all the meals have to be dispatched within a short period of time, roughly between 11.30 a.m. and 2 p.m., and the number of vans or cars in use is limited. Some of the premises were damaged during the war, and now only seven kitchens are in use, but the organization is active and anxious to expand. Invalid Kitchens of London differs from other organizations serving meals by van—for example, the Red Cross "Meals on Wheels" or the W.V.S. meals service, which in the main benefit healthy old people—in that no patient can be served without a medical prescription. The meals cost 1s., and all the commoner forms of medical diet can be supplied—meals for patients suffering from gastric or duodenal ulcers, from diabetes, and for patients requiring a salt-free diet. The kitchens also undertake to prepare any special diet which may be ordered. This service helps patients—particularly those suffering from duodenal ulcer—to return to their homes and work after a short stay in hospital, for they can obtain an appropriate diet with little trouble to themselves. In the past there has been much waste of time and money and much disruption of home life because after a prolonged and costly stay in hospital a patient has often gone home and been unable to continue with the special diet ordered; consequently the illness has recurred and a further long stay in hospital has become necessary. The encouragement and expansion of activities similar to that of the Invalid Kitchens of London will certainly help towards freeing hospital beds; better still, such services have a positive value in preventing illness.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE MANAGEMENT OF DIABETES MELLITUS

BY

WILFRID OAKLEY, M.D., F.R.C.P.

Physician, King's College Hospital Diabetic Department

Diagnosis

The discovery of a reducing substance in the urine should always be regarded as abnormal no matter what may be the age of the patient. If the partial and atypical reductions produced by drugs such as aspirin, salicylates, and chloral are excluded—and this can easily be done by stopping all medicines for a few days—persistent glycosuria is almost always due to diabetes mellitus or to a lowered renal threshold for sugar (renal glycosuria). Symptoms such as thirst, polyuria, loss of weight, lassitude, or pruritus vulvae make the diagnosis of diabetes more than probable, but a definite diagnosis of this disease should not, if possible, be made without the confirmatory evidence of a raised blood sugar.

It is bad practice to prescribe a restricted carbohydrate diet for patients with undiagnosed symptomless glycosuria, as this may result in quite needless treatment of nothing more than renal glycosuria. The diagnosis of renal glycosuria should be suspected when the glycosuria is symptomless, occurs only after meals, and is unassociated with ketosis; a family history of this condition is not uncommon.

A blood-sugar curve or glucose-tolerance test is the most certain method of diagnosis of the cause of glycosuria, but is only necessary in a very small proportion of cases. It should be carried out after the patient has been on full diet for at least a week, as a low carbohydrate diet may produce misleading results. When glycosuria is associated with symptoms of diabetes a single blood-sugar estimation performed about two hours after a good carbohydrate meal will almost always confirm the diagnosis, figures of 180 or more indicating the presence of diabetes. In the absence of symptoms when the blood sugar lies between 130 and 180 it is more difficult to be certain, and a blood-sugar curve is advisable. The association of symptomless glycosuria with a blood sugar of 120 or less is strongly suggestive of renal glycosuria, especially if a normal figure is obtained on more than one occasion. It is important to remember that the single diagnostic blood sugar should be taken about two hours after a meal, not in the fasting state. A normal result may be obtained in fasting patients with mild diabetes.

Clinical Types

Clinically, diabetics may be subdivided into two main groups—moderately severe or severe, and mild obese.

Moderately Severe or Severe.—This group consists of all children and adults up to the age of about 45, and a number of old patients of 70 and upwards. They present the textbook picture of diabetes, with loss of weight as a marked feature of the disease. They are liable to develop ketosis and if untreated may die in diabetic coma.

Mild Obese.—This group consists chiefly of middle-aged and elderly women. Obesity is a striking feature, loss of weight being insignificant or absent. Ketosis and diabetic coma do not occur. Patients of this type rarely complain of the typical symptoms of diabetes, except pruritus vulvae. Medical advice is often sought on account of this or some complication such as retinitis or vascular disease affecting the toes or feet.

The subdivision of diabetics into these two main types is not of course a hard-and-fast one. Typical severe diabetes is seen at all ages, and young cases may be mild, but the clinical picture and treatment of each group differ sufficiently to make this classification one of considerable practical importance.

Diabetes may be treated by diet or by diet and insulin. The use of insulin without diet is generally unsatisfactory and often dangerous.

Diet

It is customary to allow diabetics average amounts of protein and fat, to the extent of the Ministry of Food ration for diabetics, and to restrict only the intake of carbohydrate. Comparatively few diabetics are willing or able to weigh their food, and visual methods of estimation, though less accurate, give reasonably good results. This does not mean that scales have no place in the treatment of diabetes, as they are of great value in teaching and checking visual measurements.

A convenient form of diet card is that devised by Lawrence and used in the Diabetic Department at King's College Hospital. In this the protein foods such as meat, fish, bacon, eggs, and cheese are listed, and allowed in average helpings. The fats such as butter, margarine, cream, and olive oil are similarly treated. Green vegetables except peas, tomatoes, mushrooms, and onions are allowed without restriction; so are sour fruits such as lemons, stewing gooseberries, red currants, and rhubarb. The foods rich in carbohydrate are listed in amounts containing 10 g. of carbohydrate, and each is called a "portion" or "black line." The number of portions allowed for each meal is prescribed, and the patient can vary his diet by selecting the portions from the list provided. Greater variety can be obtained by the use of 5-g. portions, but the 10-g. method is easier and more convenient. In my opinion the technique of dieting by calorie values is more complicated than the above, is rarely understood by patients, and is open to serious theoretical objections.

In mild diabetics who are not overweight it is wise to start treatment with a diet containing about 120 g. of carbohydrate (12 portions) evenly distributed over three or four meals. If the urine becomes sugar-free the carbohydrate can be gradually increased to 150 or even 180 g. Persistent glycosuria or progressive loss of weight means that diet alone is insufficient to control the diabetes, and that the diet should be raised and the patient given insulin (see below).

When diabetes is associated with obesity it is important to reduce the patient's weight, as this is usually the best way of controlling the diabetes. In such cases the diet should contain 80 to 100 g. of carbohydrate (8 to 10 portions), and fatty foods of all kinds should be reduced to a minimum. If this fails to reduce weight and control the

diabetes the patient may with advantage eat nothing but fruit, or abstain from food altogether, for one day each week. This method of treatment should be used only in mild obese diabetics who show no tendency to develop ketosis.

Diet and Insulin

In the absence of significant ketosis it is usually wise to start treatment with a restricted carbohydrate diet without insulin. This has the double advantage of giving the patient the benefit of any doubt that may exist about the necessity for insulin injections, and of allowing time for him to become familiar with the principles of dieting before learning how to inject insulin. In a week or two it is clear in the majority of cases whether or not insulin is necessary. The persistence of heavy glycosuria, especially in the fasting morning specimen, indicates the need for insulin, and a decision must be made on the type of insulin most likely to be suitable for each case. Three insulin preparations are in common use in this country: soluble insulin (S.I.), protamine-zinc insulin (P.Z.I.), and globin insulin (G.I.). S.I. is prepared in strengths of 20, 40, and 80 units per ml., and P.Z.I. and G.I. in strengths of 40 and 80 units per ml.

Single Injection of P.Z.I.

For relatively mild cases whose diabetes cannot be satisfactorily controlled by diet alone a single morning dose of P.Z.I. often gives excellent results. The diet should be evenly distributed over four meals, and a bedtime feed of 15 to 20 g. of carbohydrate given to prevent nocturnal hypoglycaemia, the danger of which makes it wise not to exceed a maximum dose of 40 units. If this method is adopted, the urine should be tested for sugar before breakfast, the bladder having been emptied on rising; this specimen, called the second morning specimen, should be sugar-free. If the blood sugar before lunch is less than 200 mg. per 100 ml. the control may be regarded as satisfactory. There may be some glycosuria in the evening, but this is usually transitory and can be ignored. If, however, heavy glycosuria persists throughout the day, a single dose of P.Z.I. is bad treatment, and the insulin dosage should be changed to a mixed injection of S.I. and P.Z.I., or to morning and evening injections of S.I.

Mixed Injection of S.I. and P.Z.I.

The mixed-dose method of treatment is suitable for diabetics who lead reasonably regular lives with regular mealtimes. It is less suitable than two injections of S.I. for those whose occupation makes this type of life impossible. The diet should be so arranged that the greater part of the carbohydrate content is taken in the earlier part of the day, while the S.I. is active. The following is a suitable arrangement of carbohydrate for use with a mixed injection of S.I. and P.Z.I.

Breakfast	40 to 60 g.
Lunch	40 g
Tea	30 g
Evening meal	30 to 40 g.
Bedtime	15 to 20 g.

Treatment may be started with a single dose of P.Z.I and S.I. added later, or a mixed injection may be given from the outset. It is well to remember that when these two insulins are mixed a certain amount of S.I. is converted into P.Z.I., and the dose of the former should therefore in most cases be equal to or larger than that of the latter A convenient way of starting treatment is to give equal amounts of S.I. and P.Z.I., 12 to 16 units being a suitable order of dosage in cases of moderate severity. The dose of S.I. is then adjusted until the urine test (or, better, the blood sugar) is satisfactory at the time of maximum S I action—that is, before lunch for doses up to about and before tea for larger doses. P.Z.I. should be a from the second morning specimen in the manner above. The persistence of heavy glycosuria bef evening meal, especially if it is associated with keto recurrence of diabetic symptoms, such as thirst or p may be treated by the addition of an injection of S.I tea or supper. In these circumstances, however, i to consider whether it would not be better to give the morning and evening injections of S.I. or the modif of this form of treatment described below.

Morning and Evening Injections of S.I.

This is the oldest and one of the best methods of tre diabetes with insulin. It has the advantage of simplicity and elasticity, it allows a relatively large breakfast and evening meal, and the time of the latter can be varied within reasonable limits. The times at which hypoglycaemia reactions are apt to occur are easily predictable, and suitable precautions can therefore be taken to prevent this important and potentially dangerous complication. The disadvantages are the necessity for a second injection and the tendency in severe diabetics for a relapse to occur before breakfast, owing to the relatively short duration of action of S.I. It is important to remember that the duration of action of S.I. or any other insulin is proportional to the size of the dose injected. A relatively large dose of S.I. can be given before breakfast, and any tendency to hypoglycaemia corrected by means of a mid-morning feed of about 20 g. of carbohydrate. In the evening it is usually not safe to give such a large dose, so there is a greater tendency for relapse to occur about 8 to 10 hours after

SCHEME OF TREATMENT

	Diet Alone		Diet and Insulin			
	Trial Diet*	Reducing Diet†	Single Injection of P.Z.I. →	Mixed Injection of S.I. and P.Z.I. →	Morning and Evening S.I. →	Morning S.I Evening S.I. and P.Z.I →
Breakfast	40	20–30	40	40–60	40–60	60
11 *a.m.*	—	—	—	—	20	20

(A pulthes to cease payne devised by DR. BUTTS)

Today the physician has, in 'Physeptone,' a specific agent for the relief of pain. 'Physeptone' is more powerful than morphine and does not cause hypnosis or constipation. It may with advantage replace morphine as an analgesic for patients confined to bed. 'Physeptone' is available as 5 mgm compressed products for oral administration (bottles of 25, 100 and 500). and as injection, 10 mgm. per c.c. (ampoules of 1 c.c., in boxes of 12).

'PHYSEPTONE'

'Albucid' Soluble in Ocular Therapeutics

FOR TISSUE of the highest sensitivity it is essential that local chemotherapy be effected by agents free from irritation. 'Albucid' Soluble Eye Drops are adjusted to pH 7.4 and are thus free from irritating alkalinity. High therapeutic efficiency, combined with ready solubility and very low toxicity, makes 'Albucid' Soluble the agent of choice in most eye infections. 'Albucid' Soluble Eye Ointments, containing 'Albucid' Soluble in a neutral cream base, are available for the treatment of infections of the eye and lids, where a slower and more prolonged absorption may be considered advantageous.

the injection. The following modification of this method of treatment is usually successful in preventing this form of relapse, and is particularly suitable for the control of very severe diabetics, pregnant diabetics, and some children.

Morning S.I. and Evening S.I. with P.Z.I.

The addition of a small dose of P.Z.I. to the evening injection of S.I. tends to prevent early morning ketosis and controls the fasting blood sugar. The smallest dose of P.Z.I. which prevents morning ketosis should be given in most cases, and the best results are obtained when the mixed evening injection is given not later than 6 p.m. When given early in this way the S.I. has passed its period of maximum action by the time the patient goes to bed, and a buffer feed on retiring reduces the risk of hypoglycaemia during the night. The P.Z.I. acts relatively weakly but continuously throughout the night, and in consequence morning ketosis is abolished and the fasting blood sugar prevented from rising to too high a level. If too much P.Z.I. is added to the evening dose of S.I. the fasting blood sugar may be made so low that it is impossible to give an adequate dose of S.I. before breakfast without producing severe hypoglycaemia during the late morning. For both of these arrangements of insulin the diet should be prescribed in some such manner as the following.

Breakfast	60 g.
11 a.m.	20 g.
Lunch	40 g.
Tea	0 g.
(or 20 g. if the morning S.I. exceeds 40 units)	
Evening meal	60 g.
Bedtime	20 g.

Urine tests should be made before lunch or tea, whichever is the better. The time will depend largely on the size of the morning dose of S.I., more resistant patients often giving the better test in the afternoon.

Globin insulin (G.I.) may be used alone instead of P.Z.I. as a single injection method of treatment, or may be mixed with S.I. and given once or twice a day. Given alone before breakfast G.I. will often control relatively mild diabetes satisfactorily, but small doses tend not to maintain their action throughout the 24 hours, while large doses of 40 units or more are liable to produce severe hypoglycaemia before lunch or tea. G.I. is useful in those cases in which P.Z.I. fails to control hyperglycaemia by day but causes hypoglycaemia during the early hours of the morning. It gives good results in some difficult very insulin-sensitive cases also, in which it may be given by morning and evening injections, either alone or with a small dose of S.I. The diet for a single dose of G.I. is the same as that for a single dose of P.Z.I. with the omission of the bedtime feed.

Urine Tests

It is important to realize that urine tests should be made at the time of maximum insulin action, not after meals. Most diabetics, however good their treatment, are likely to pass sugar after eating. Attempts to render the urine sugar-free after meals may result in severe hypoglycaemia before the next meal. Always, therefore, test the urine before meals and at the time when the type of insulin used is known to be exerting its maximum action. In the case of P.Z.I. this will be before breakfast, and with S.I. about four to eight hours or more after injection, according to the size of dose. The bladder should be emptied half to one hour before the urine for testing is passed, so that the result is not confused by the presence of sugar secreted after the previous meal

Children

The treatment of children is similar in principle to that of adults, but insulin is required in almost every case. Children are usually very sensitive to insulin, with the result that there may be wide fluctuations in blood-sugar level, periods of heavy glycosuria giving place rapidly to hypoglycaemia. The aim of treatment should be to provide an adequate and reasonably attractive diet, to avoid ketosis, and to render the blood-sugar level normal, or nearly so, for some period of the 24 hours. Any attempt to keep the urine perpetually sugar-free is bound to result in hypoglycaemic reactions. If these aims can be achieved with a single injection daily, so much the better for the child and those caring for it. Very often, however, especially at or about puberty, it is necessary to change over to two injections. S.I. before breakfast and S.I. with P.Z.I. before tea is a particularly suitable method of treatment at this difficult period in the life of the child diabetic.

The diagnosis and treatment of ketosis, including diabetic coma, and hypoglycaemia will be considered in next week's article.

SIR FELIX SEMON*

HIS CONTRIBUTION TO LARYNGOLOGY

BY

R. SCOTT STEVENSON, M.D., F.R.C.S.Ed.

Felix Semon was born in Danzig on December 8, 1849, the son of a substantial merchant. He was educated at Heidelberg and at Berlin, and took the Berlin M.D. in the summer of 1874. His training had been interrupted by the Franco-Prussian War of 1870–1, when Semon served as a "one-year volunteer" in the Prussian Uhlan Guards, seeing some active service. After graduation he went on to spend a postgraduate year at Vienna and London, studying particularly the various specialties. In London he visited the chief teaching hospitals, finally attaching himself to the medical wards of St. Thomas's, where an old friend of his mother's, Richard Liebreich, was in charge of the eye department. Semon also attended the Brompton Hospital, Moorfields, and the Throat Hospital, Golden Square; at the last he had a letter of introduction to its founder, Morell Mackenzie, from an old friend of Mackenzie's, Fürstenberg, of Berlin. Laryngology was then a brand-new specialty, with exciting new methods of diagnosis and treatment presenting themselves almost every month, and Semon determined to embrace the opportunity presented in London, attending Golden Square Hospital with redoubled zeal.

By permission of *Journal of Laryngology and Otology.*

In March, 1876, Semon approached Mackenzie to know what his views would be if he were to stay on in London, and Mackenzie kindly promised him that as soon as possible he would get him appointed a physician to Golden Square Hospital—this less than a year after he had come to England. He passed the M.R.C.P. examination in October, 1876, was elected to the old Royal Medical and Chirurgical Society, and began private practice at 6, Chandos Street.

*A shortened version of a paper read at a meeting of the Osler Club on December 1.

In the peaceful and spacious days of Queen Victoria it was no disadvantage in London to be German. Queen Victoria herself liked to converse in German, as she had done with her dear Prince Albert, and it may be remembered that King Edward VII spoke with a marked German accent and numbered some Germans among his intimate friends. Musical London—and those were the great days of Melba and Caruso, Joachim, Rubinstein, and Paderewski—was dominated by the German element. Semon was a good pianist and a composer of ability, and made many musical contacts among his fellow countrymen.

Felix Semon undoubtedly made his mark as secretary of the Subsection of Laryngology at the great International Congress of Medicine in 1881. He was the most active of the secretaries and managed the affairs of the Subsection in a masterly manner, and by the time the Congress was over everyone in Europe or America associated with laryngology was well acquainted with his name. In 1882, backed by his friends MacCormac, Bristowe, and Ord, though not without some opposition, Semon was made head of the throat department at St. Thomas's Hospital, and was the first laryngologist to be appointed to any general or teaching hospital in this country. In 1884 he founded the *Centralblatt für Laryngologie*, published in Berlin, for many years the leading laryngological journal.

In any matter of laryngological interest he took a leading part. He was knighted in 1897, and when he retired from active practice in 1911 he was at the zenith of his career. The £1,200 that had been subscribed by friends and colleagues as a testimonial on his retirement he applied to endow the Semon Lectureship in Laryngology.

Cancer of the Larynx

Semon prided himself chiefly on his work on cancer of the larynx; in his autobiography he claims "the world's record for laryngeal cancer, 80% of lasting cures." But his idea of a "lasting cure" was a patient who survived for one year after operation. He includes in his cases patients whom he diagnosed but did not operate upon, and the 80% refers to laryngo-fissure patients only. Semon insisted that a malignant growth was more common in the posterior part of the vocal cords—this is quite wrong, and helped to mislead a whole generation. He said that a malignant growth caused greater hoarseness than an innocent growth, and that impaired mobility was an early sign of cancer of a vocal cord. All of these points Semon used to try to discredit Morell Mackenzie in his management of the case of the Emperor Frederick III—yet subsequent experience has shown that he was wrong in every one of them. It is true, however, that Semon's advocacy of the operation of laryngo-fissure did much to advance the surgery of cancer of the larynx. But it was Sir Henry Butlin, not Semon, who revived the previously discredited operation of laryngo-fissure, and Semon was wise enough never to attempt the operation without a skilled surgical assistant. Semon's contribution to advances in the study and treatment of cancer of the larynx is mainly that of an ardent propagandist, undoubtedly useful in the times in which he flourished, but his work in this field has had little permanent value.

Semon did good work in advocating complete vocal rest in the treatment of laryngeal tuberculosis. He read a paper, with a long and detailed report of seven cases, at the Berlin Laryngological Society in 1906, and subsequently published it in the *British Medical Journal*. But the idea dates back to Broussais in 1824, and Professor Moritz Schmidt, of Frankfort, advocated it in 1887, while others claimed to have done so about the same time.

Innervation of the Larynx

Before Semon laryngologists had quite chaotic ideas about laryngeal paralysis, and whether the abductors or the adductors were affected seemed to depend entirely on chance. Semon published many papers on the innervation of the larynx and laryngeal paralysis, and there is no doubt that he did clear up many misconceptions on this subject. He was not a trained physiological worker, and his early experimental work was unsuccessful, as he himself says, owing to deficiencies in technique; but after he made the acquaintance of Victor Horsley in 1884 he found a helpful collaborator, experienced in physiological investigation, and Semon's enthusiasm with Horsley's skill produced fruitful results. Semon's observation that in progressive organic lesions the nerves supplying the abductor muscles of the larynx are affected before those of the adductors has been termed "Semon's law." The name became attached mainly because Semon wrote so much and so vehemently on the subject when it was first promulgated. The idea had been in Semon's mind, he had said something about it at the Clinical Society of London in 1878, and in the German edition of Mackenzie's great textbook, *Diseases of the Throat and Nose*, translated and annotated by Semon, he elaborated this in a footnote, but Professor Otto Rosenbach actually published his own observation about the abductors and adductors in 1880 before Semon. The battle of priority was fought with considerable violence on both sides and a bitter controversy ensued.

Semon's main contribution to laryngology really lies in his having enhanced the status of the specialty. His published work, though much of it is naturally out-dated, was founded on personal observations and always carefully documented. He was an assiduous attendant at meetings of societies and conferences, and, at home and abroad, was in his generation looked upon as the representative English laryngologist—though in the end he preferred to print his collected papers (in two handsome volumes) in German. His geniality and courtesy, his generous hospitality and vivacious conversation, made him a conspicuous figure and a general favourite in the society of late Victorian and Edwardian London. He was undoubtedly vain and self-centred, but he was a hard worker and lived for the advancement of laryngology. The centenary of his birth well deserves to be remembered.

Speaking on "The Need for Smoke Abatement" at the Royal Institute of Public Health and Hygiene on November 30, Sir George Elliston said that a report recently issued by the Federal Health Authority in Washington on last winter's fatal smoke fog in Donora—when over 20 people died and 40% of the population were made ill—showed that the chief culprit was sulphur dioxide, the corrosive constituent of our own fogs. "About the same time, here in London, a week of fog sent up deaths by 20 to 30% over the average for the previous four weeks, while the number of deaths from bronchitis was more than doubled." Those whose lungs were not as efficient as they might be should be warned to take special care of themselves and to remain indoors as much as possible during heavy smoke fogs. Discussing the remedies for the problem, Sir George said there was no simple panacea. The remedies were identical with the needs and programme for using our fuel supplies more efficiently and wisely and with the improvements that were so badly needed for warming our homes. He referred to the need for new legislation based on the prior approval of new fuel-burning installations, which was now standard practice in the U.S.A. and elsewhere overseas. The domestic smoke problem for a long time seemed to be insoluble. But in 50 years' time or less the old-fashioned coal fire would be as obsolete as the open sewer to-day. The abolition of smoke by stages through the setting up of expanding smokeless zones was preferable to any of the more spectacular ways that might be envisaged. Smokeless zones were areas where all smoke was prohibited, and though the central and administrative areas were an ideal starting point it was hoped that new residential districts, rebuilt blitzed areas, new industrial estates, and above all new towns would become smokeless zones. In time the separate zones would coalesce and whole cities and industrial districts become smokeless.

SCIENTIFIC TREATMENT OF DELINQUENCY

INSTITUTE'S ANNUAL MEETING

The eleventh annual general meeting of the Institute for the Scientific Treatment of Delinquency was held on November 18, with Dr. Edward Glover in the chair. Dr. Dennis Carroll, who presented the annual report, said that the year had probably been the busiest and most successful in the Institute's history. The clinic, on the council's recommendation, had become a part of the National Health Service, the Institute remaining a private society pursuing its other activities. This necessitated a division between the clinical and non-clinical work, and the placing of the clinic under the North-West Metropolitan Regional Hospital Board.

After mentioning a number of developments Dr. Carroll described one which had attracted a good deal of attention—namely, play therapy as a method of dealing with highly aggressive children between the ages of 8 and 11. Some of these children in ordinary life were dangerous, and all were aggressive enough to be regarded as uncontrollable. They were set to play in a specially designed room with materials that could cause no injury, and were allowed to be as aggressive as they liked; it took two adult play-therapists to control four aggressive children. The children also received individual treatment. After a few months they spontaneously became constructive instead of destructive, and were transferred to another room where they could be constructive to their hearts' content. This technique was still in the experimental stage in the sense that its limits were not yet known, but it was established that it was worth doing. Dr. Carroll complained that children were often not referred until they had a history of some years of delinquency, which made it necessary not only to overcome the original cause but to exorcise an extremely bad habit.

The Earl of Feversham said that the stage had been reached when the conscientious citizen was aware of the work which had grown up at the Institute. People were at last beginning to ask why children were naughty, and once the beginning of an answer to that question was made the problem of juvenile delinquency began to be solved. He thought it a great advantage that the work of the clinic had been taken over by the National Health Service and the Institute left free for research and education, even though its appeal to the public was now less dramatic.

ENCEPHALITIS AND ENCEPHALOMYELITIS

HUGHLINGS JACKSON LECTURE

The Hughlings Jackson lecture was delivered before the Section of Neurology of the Royal Society of Medicine on November 22 by Dr. J. G. Greenfield, whose subject was "Encephalitis and Encephalomyelitis in Man." Mr. Julian Taylor presided.

Dr. Greenfield, whose lecture was accompanied by many photomicrographs of brain sections, said that he could find no evidence that Jackson took a special interest in this subject. Perhaps acute cases of this kind did not lend themselves to the detached and protracted study which he gave to his cases, but if his working life had been twenty years later the sequelae of encephalitis would have fascinated him, and no doubt his keen analytical mind would have clarified the problems they presented.

Encephalitis had now largely passed into the hands of virus experts, and in this field the laboratory worker had recently outstripped the clinician. But the reverse side of the picture, that of the histopathologist, showed five or six different types of encephalitis which had so far resisted attempts at transmission to animals, or at least had given uncertain results. In the diagnosis of these cases the histopathologist retained an important place. The lecturer confined himself to the forms of encephalitis which were, or might be presumed to be, due to infection by a virus either directly or by reaction of virus and host in a manner not yet fully understood. He gave a short historical survey of encephalitis in man from the sixteenth century onwards. Towards the end of the nineteenth century the chief interest in encephalitis was in relation to influenza. Pfeiffer's bacillus was incriminated in many cases. Acute haemorrhagic encephalitis was almost synonymous with influenzal meningitis. The state of knowledge in England was well summed up by Frederick Batten early in this century. Batten recognized encephalitis following measles and other acute infectious diseases, and stated that influenzal meningitis might give rise to symptoms very similar to those of encephalitis. At that time there seemed to be little conception of encephalitis as an independent disease.

In the epidemic of encephalitis lethargica in 1917 the most curious symptom noted was the lethargy or light coma. Its sequelae of oculogyric crises and parkinsonism were not known to follow any other form. On the whole, the course of this disease was less acute than that of other forms of encephalitis, though many acutely fatal cases did occur. It seemed that we were still ignorant of the virus causing encephalitis lethargica, possibly because no suitable animal host had as yet been found. In this disease the white matter of the hemispheres was little if at all infiltrated; the basal ganglia often showed severe lesions.

Cases of encephalitis following vaccination against smallpox began to be observed in 1922. These were at first interpreted as a direct attack on the brain by a vaccinal virus. It was not long, however, before cases of encephalitis with a similar histological picture were observed following measles in the larger centres of population, and other cases following influenza, rubella, chicken-pox, and mumps were recorded. The aetiology of this condition had to be reconsidered. One possibility was activation of another virus that was capable of causing demyelination or necrosis. Another was an allergic response of the brain to the previous infection. By 1930 cases of post-vaccinal encephalitis had become rarer, but they became rather more numerous during the recent war. This post-infectious form of encephalitis, though rare, was still the most common type in the British Isles at the present time.

Meanwhile various epidemics had been happening, or were about to happen, some of them in the Far East and the Antipodes, others in America. Dr. Greenfield gave some account of the Australian X and Japanese B forms. In the late summer of 1933 an epidemic occurred in St. Louis, with a low death rate and practically no sequelae. It appeared to be carried by mosquitoes, probably from an animal or avian reservoir, in which it was probable that the disease was carried through the winter by mites or ticks. In 1938 outbreaks of equine encephalomyelitis were reported from the eastern seaboard and the western States of the U.S.A. That in the east was small, but with a high death rate in children. In the western States the epidemic was widespread and the condition had now become endemic. In all five of these forms the disease occurred only in the late summer, when mosquitoes were most numerous.

An outbreak of encephalitis in East Russia, occurring in spring and early summer and noticed about 1932, was found by a commission of investigation to have been carried by ticks from the wild animals in Siberia to the human population. Not uncommon also in the western area of Russia were cases of a progressive or relapsing type in which the peripheral musculature was more affected than the shoulder-joints and neck, which were most often affected in the Siberian cases.

Epidemics of the insect-borne forms of encephalitis were determined as to their seasonal incidence by the life habits of the insect vectors. But there were several other factors affecting the epidemiology, the first being the establishment of immunity both in the human and animal hosts. Just as in epidemics of poliomyelitis there were many cases without paralysis for every case of paralysis, so here there were many cases of fever only for each case which showed neurological symptoms. The phenomena of interference and exaltation of virulence, one or the other of which might occur when two viruses were combined, had also to be considered.

Encephalitis in the British Isles

Dr. Greenfield then passed to a specific consideration of the various forms of encephalitis in the British Isles at the present time. Some were quite rare, such as acute cases of the pan-encephalitic type, of which during the last eight years he had

examined only ten from different parts of the country. In most of these cases attempts were made to transfer the disease to animals, but without success. The cases were found generally in adolescents or young adults between the ages of 15 and 35. The intensity of the inflammatory changes in the brain varied remarkably.

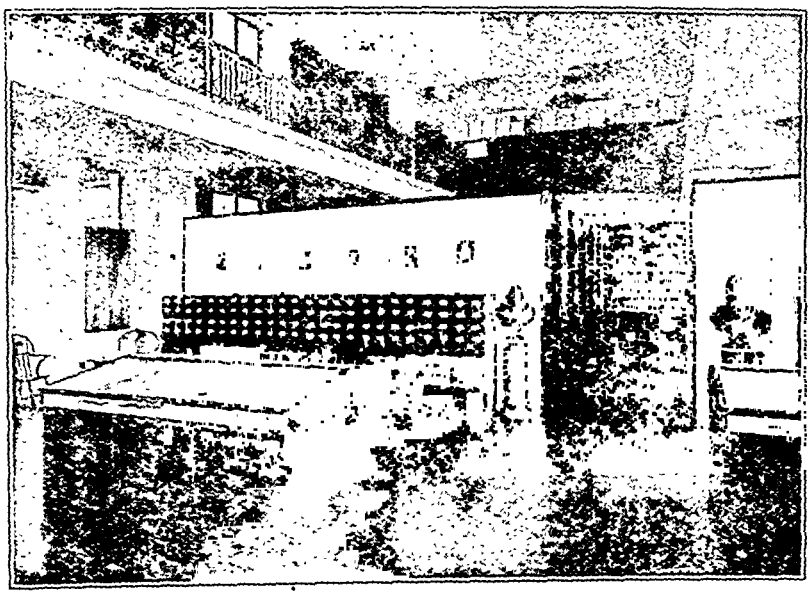
Cases of acute haemorrhagic leuco-encephalitis had recently been reported in Boston, Mass., and in Norway. Some of them were interesting in that the disease was almost entirely in the pons or brain stem. Most of these cases came on after infections of the respiratory tract, such as sore throat, influenza, coryza, or acute bronchitis. In one patient he had personally examined the symptoms came on two days after an attack of urticaria, the history suggesting an allergic reaction of the brain tissue. The onset of the condition after influenza or an acute respiratory infection, sometimes with an interval of a few days of relative health, suggested a possible relationship between this condition and the commoner form of post-infectious encephalitis, and this was borne out by recent experimental work.

Subacute forms of encephalitis presented a rather distinctive clinical course. He mentioned eight cases of subacute inclusion-body encephalitis in children. The disease came on gradually, sometimes over a period of weeks, and pursued a ruthlessly progressive course to a condition of complete loss of mentality. At an earlier period of the disease, in all but one of the cases studied, myoclonic jerking movements or repeated spasms of the face or limbs or of the entire body had been observed. Death had occurred after an interval of from seven weeks to six months from the first symptom.

The subacute sclerosing form of encephalitis described by van Bogaert in 1945 was not easily distinguished from the subacute inclusion-body type on clinical grounds. In it also there was progressive dementia with involuntary movements, which might resemble those just described or might be of a writhing character. In both subacute forms the cerebrospinal fluid, though otherwise normal, might give a Lange reaction of paretic type. Histologically the sclerosing form showed neuroglial proliferation and early gliosis in the cortex and areas of partial demyelination with gliosis in the white matter. In both forms the usual evidences of inflammation were found in the cerebrum and brain stem.

The lecturer closed by saying that the belief that encephalitis might occur in a subacute progressive form, although suggested by some of the earlier cases, had only recently been fully documented. Few had worked in this field, but it was one which was full of interest and offered a rich harvest.

At the close of the lecture Professor Ludo van Bogaert, of Antwerp, offered a few observations. He agreed with the lecturer that the two subacute forms he had described were clinically indistinguishable. He had recently found several such cases in colonies of mental defectives. A vote of thanks to Dr. Greenfield was proposed by Dr. F. M. R. Walshe, who said that the Hughlings Jackson lectureship was the highest honour which British neurology could offer to anyone working in this field. The lectureship had always been filled by a most distinguished neurologist, but this was the first time that neuropathology had had the honour. Dr. Greenfield's contributions to neurology over the last thirty years were well known, and in moving the vote of thanks he had the double satisfaction of paying a modest tribute to Dr. Greenfield's distinction in his chosen field and of expressing his affection for a man whom he had known for so many years.

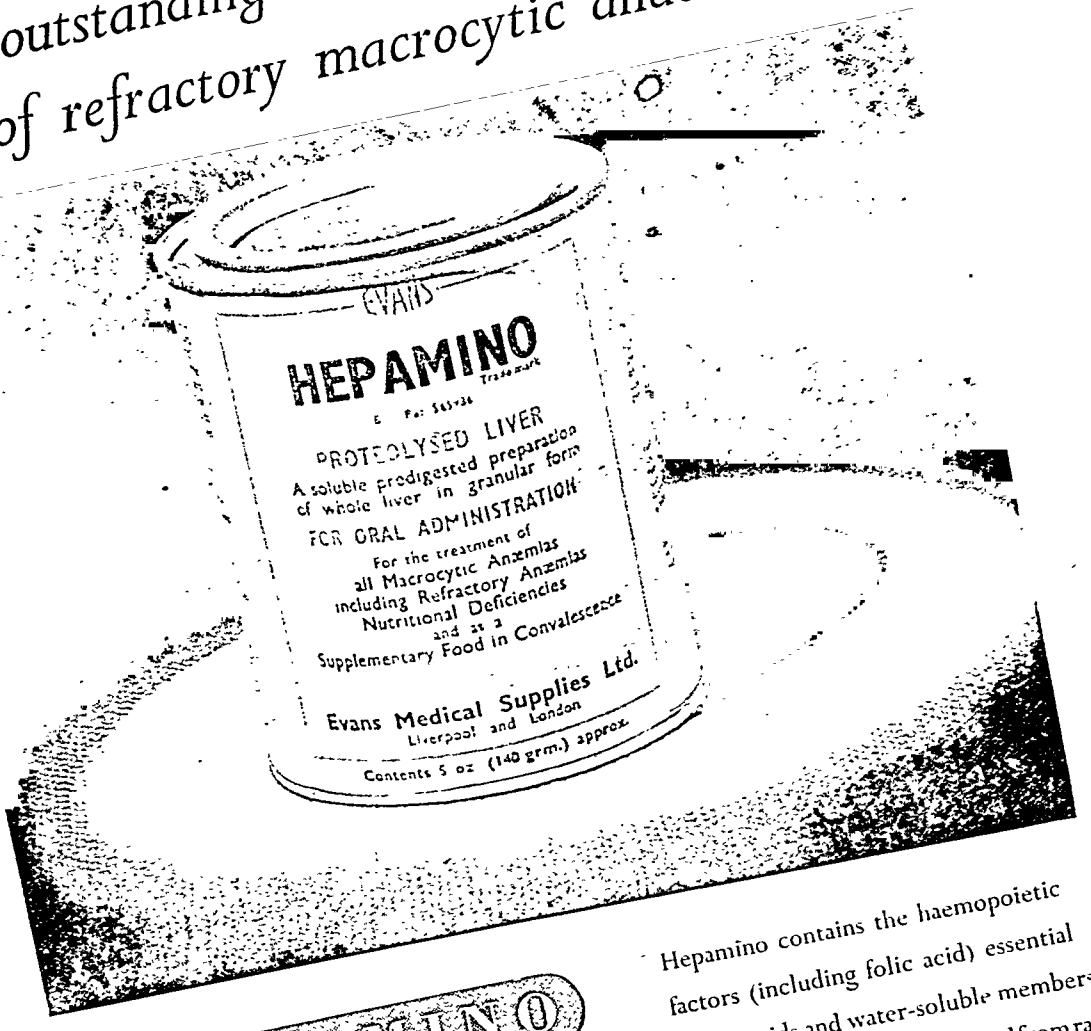


WELLCOME HISTORICAL MEDICAL LIBRARY

The Wellcome Historical Medical Library was formally opened on December 2. Welcoming the guests to a luncheon given by the Directors of the Foundation, Mr. H. E. Sier (chairman) said it was a great privilege to see there so many librarians, representing most of the large libraries in England. He spoke of the late Sir Henry Wellcome's great interest in medical history and archaeology, which had led him to build up the library. Dr. E. Ashworth Underwood (Director of the Library and Museum) recalled that Sir Henry had by 1900 acquired a considerable collection of museum pieces and books, and in 1913 he was able to provide a medico-historical exhibition at the International Congress of Medicine in London. Considerable progress had been made in the preparation of the library catalogue, and he paid tribute to the Librarian, Mr. W. J. Bishop, and his staff for their achievement in bringing the library to its present state of efficiency. Sir Arthur MacNalty and Sir Henry Thomas also spoke.

The Library

The library has been built up in the last 50 years on a scale comparable, in its own subjects, to that of the great national collections. It contains 200,000 books, pamphlets, and journals, 5,000 manuscripts, and 100,000 autograph letters. It includes 612 complete works and 22 fragments of books published before 1500, which is one of the largest collections of incunabula in the country. Among these are to be found Aristotle's *Problemata* (1500), of which there is only one other copy in existence, and his *De physico* (1500). The copy of Quiricus de Augustis: *Lumen apothecariorum* (1497) is the only one in any British library. Other titles include Avicenna's *Canon* (1489–90), Ferrarius de Gradibus: *Consilia* (1482), Gilinus: *De morbo gallico* (1497), the only copy in Britain, and Hippocrates: *De natura hominis* (1480).



The sixteenth century is represented by 4,000 volumes, including the Renaissance editions issued by Aldus, Froeben, the Estiennes, Junta, Oporinus, and other scholar printers. The library contains all the editions of Vesalius and his forerunners, the works of Jerome of Brunswick, Hans Gersdorff, Ambrose Paré, Paracelsus, Della Croce, Pierre Franco, Vidus Vidius, Marianus Sanctus, and other pioneers of surgery. There are to be found on the shelves rare early herbals by Dioscorides and the well-known Mainz Herbal of 1491.

Among the 700 English books printed before 1640 are Gilbert's *De Magenti* (1600), Roesslin's *Byrth of Mankinde* (1540) and Vigo's *Surgical Works* (1586) autographed by William Clowes, the Elizabethan surgeon. The seventeenth-century collection contains 10,000 books, including not only such medical works as Harvey's *De Motu Cordis* (1628) but first editions of Bacon, Galileo, Kepler, Descartes, Newton, and Boyle.

The library contains special collections on, for example, alchemy, occultism, veterinary

An outstanding advance in the therapy of refractory macrocytic anaemia

HEPAMINO

A PROTEOLYSED WHOLE LIVER PREPARATION IN GRANULAR FORM FOR ORAL USE

Hepamino contains the haemopoietic factors (including folic acid) essential amino acids and water-soluble members of the vitamin B complex derived from raw liver. It is indicated for the treatment of all macrocytic anaemias (including refractory types) and nutritional deficiencies.

EVANS MEDICAL SUPPLIES LTD LIVERPOOL AND LONDON

fulfils the single purpose of PAIN RELIEF

Clinical experience with 'Heptalgin' in the relief of all types of pain has not merely confirmed the remarkable analgesic properties of the compound. Equally remarkable has been its relative freedom from undesirable side effects. For instance, 'Heptalgin' is free from euphoriant effects. It causes little or no depression or drowsiness—indeed, if both sedation and pain-relief are called for, then a sedative must be administered in addition to 'Heptalgin'.

As with other analgesics, the dosage of 'Heptalgin' varies markedly from patient to patient. It is advisable to start with a dose of one tablet, increasing to a single dose of perhaps three or four tablets if response to the smaller amount is too slight.

WELLCOME HISTORICAL MEDICAL LIBRARY

medicine, and folklore, mediaeval texts, and original manuscripts from such figures as Hunter, Pasteur, Lister, and Florence Nightingale. There is also a large collection of modern works.

The library is now open at the Wellcome Research Institute, 183, Euston Road, between 10 a.m. and 5 p.m. from Monday to Friday throughout the year, apart from the usual Bank Holidays.

Reports of Societies

METHODS OF PREVENTION IN PSYCHIATRY

Professor T. FERGUSON RODGER, of the Department of Psychological Medicine, Glasgow University, addressed a meeting of the Leeds Regional Psychiatric Association in Leeds General Infirmary on November 18. The meeting was arranged by the subcommittee on education and public relations of the association, and Professor D. R. MACCALMAN was in the chair.

Professor RODGER described his experiences as a member of the subcommittee on mental health of the World Health Organization and discussed the principles for mental health organization which this subcommittee had formulated. The committee was representative of psychiatry in Britain, the United States, China, Czechoslovakia, Brazil, and India. The facilities for psychiatric treatment throughout the world were surveyed and found to be generally inadequate to meet the demand—grossly so in Asiatic countries. In these circumstances the need for preventive measures was paramount; yet even in the advanced countries prevention was a relatively new field. The most suitable field for the development of preventive services was in the public health service, which would have to establish an organization equivalent to that already provided for dealing with the problems of communal physical health. Mental hygiene departments of the kind visualized would require the assistance of research workers in sociological and psychological aspects of the work. The international subcommittee regarded mental health work among university students as of great importance, since the majority of these individuals would hold responsible positions in the community.

In the course of the discussion which followed methods of prevention in psychiatry were described. The need for instruction in the aims and methods of psychiatry for influential laymen, such as industrialists, trade union officials, and teachers, was emphasized. The importance of the health visitor, her influence on parents, and her part in conveying knowledge on the management of children was stressed.

The U.S. Public Health Service has recently made grants amounting to nearly $1,000,000 to aid laboratory and clinical research. The awards were made by the National Cancer Institute to hospitals and universities in 21 States. With the aid of these funds several of the institutions will investigate the relationship of cancer and hormones. Drs. R. W. Rawson and H. J. Tagnon, of the Memorial Hospital, New York, will study the role of human liver in reducing the activity of oestrogen. The investigators will make use of sections of human liver which have had to be removed in the course of treatment for various diseases, including cancer, with a view to finding out if liver from patients with and without cancer differs in ability to make the hormones inactive. In earlier studies liver from patients with cancer of the uterus failed to inactivate oestrogen. Thus a damaged or diseased liver may contribute to the development of cancer in organs stimulated by hormones. A tracer study of "cortisone" will be supported through a grant to the St. Louis University School of Medicine. By tagging cortisone with radioactive carbon, the investigator, Dr. E. A. Doisy, will trace the drug through the bodies of laboratory animals, in order to learn its path and mode of action. Previous studies by Dr. Doisy, a Nobel Prize winner, have shown that less than 10% of administered cortisone is excreted in the urine, but the remainder has not been accounted for.

Correspondence

Silico-tuberculosis

SIR,—Dr. H. Midgley Turner and Dr. W. J. Martin's paper on mortality and survival rates in males with silicosis and silico-tuberculosis (November 19, p. 1148) is of great interest and value, but one essential piece of information is omitted. We are not told the grounds on which the two conditions were distinguished. It might be concluded from the tables that 50% of cases of silico-tuberculosis aged 40 have a chance of reaching the age of 58. If the diagnosis of silico-tuberculosis were based on positive bacteriological findings this is an astonishing conclusion, unless the majority of such cases were diagnosed long after the age of 40 and assumed to have been tuberculous since that age. Presumably, therefore, the diagnosis was based upon other grounds, which should be stated.

I am quoted as suggesting that in pneumoconiosis of coal-miners "clinically tuberculosis appears as an infrequent but often serious complication of the disease." It is the belief of myself and my colleagues that massive fibrosis in coal-miners' pneumoconiosis is nearly always the expression of tuberculous infection in a lung that is already affected by simple pneumoconiosis.[1] If this is correct, tuberculosis is a common complication of coal-miners' pneumoconiosis. It is serious in that it leads to considerably more disability than simple pneumoconiosis and ultimately in many cases to death from respiratory failure. A positive sputum in such cases is, however, uncommon: Stewart[2] found it in about 3% of her cases. When the sputum is positive the man is usually ill and seldom survives more than two years. Out of 13 cases with a positive sputum whom we have studied as in-patients up to two years ago, only one survives to-day. Thus, in coal-miners' pneumoconiosis at any rate, the diagnosis of "silico-tuberculosis" is a serious one. It only becomes grave when the sputum is positive.

Turner and Martin also state that the prognosis of silico-tuberculosis in coal-miners is better than the prognosis of comparable cases in grinders. It would again be interesting to know whether they mean comparable bacteriologically or comparable radiologically. Owing to the profound differences in the method of deriving the figures their tables are not comparable with those produced by Stewart[2] for the survival of certified cases of coal-miners' pneumoconiosis, but her figures suggest a very much graver prognosis for cases of coal-miners' pneumoconiosis after certification (which in most cases is the time at which symptoms lead the man to seek medical advice) than that given for all cases of silico-tuberculosis by Turner and Martin.

I feel there are grave disadvantages in Turner and Martin's method of deriving prognosis by extrapolation into the past and that Dr. Stewart's figures may be more helpful to medical men concerned with cases of coal-miners' pneumoconiosis.—

I am, etc.,

C. M. FLETCHER.

Penarth, Glamorgan.

Treatment of Ringworm of the Scalp

SIR,—Dr. K. D. Crow, in his letter (November 19, p. 1175) in which he discusses local versus *x*-ray treatment of tinea tonsurans, lists a series of disadvantages of the latter method and quotes nine cases of incomplete regrowth after epilation that I have reported in 2,400 epilations. May I set some of these disadvantages in their proper background?

1. It is surely unusual for cases of ringworm of the scalp to have to wait 3–4 months for *x*-ray treatment. This certainly does not apply to London. We have no waiting-list at Goldie Leigh Hospital.

2. The risk of permanent alopecia is now extremely remote in properly organized radiotherapy centres. The nine cases I

reported all occurred in September and October, 1927, when the apparatus available was primitive, and the dosimeter still more so. Since then I have treated 2,350 cases at Goldie Leigh Hospital without a single mishap.

3. Dr. Crow is wrong in stating that *x*-ray epilation is unsuitable for young children. We treat children from one year upwards. Those who are too young to remain still of their own volition can be simply and safely restrained on the couch I described in 1931.

I agree that if the local applications advocated by Brain and his colleagues (April 17, 1948, p. 723, and September 17, 1949, p. 626) are successful they should be used in preference to epilation, but in assessing the alternatives the difficulties and dangers of the *x*-ray methods should not be presented as serious when in fact they are now negligible.—I am, etc.,

London, W.1. S. COCHRANE SHANKS.

Aureomycin in Treatment of Syphilis

SIR,—Dr. R. R. Willcox has shown (November 12, p. 1076) that this drug has some action in early syphilis. This was already known. I deprecate the unscientific trial of therapeutic agents in syphilis, and the premature publication of results.

In syphilis, more than other diseases, therapeutic trials must be planned and controlled, and deductions must be based on scientific tests and prolonged observation. The prevalent abuse of antibiotics in syphilis is fostered by unscientific trials and premature reports.—I am, etc.,

Manchester. ROBERT LEES.

Botulism or Polio-encephalomyelitis?

SIR,—I have read with interest the comments of Drs. E. Vivian Lambert and A. H. Gale (November 26, p. 1235). Certain features of this patient's illness made a diagnosis of poliomyelitis very unlikely: two members of the family had similar prodromal symptoms; the interval between onset of gastro-intestinal symptoms and paralysis was only a matter of hours; signs of meningeal irritation were absent; and an isolated internal ophthalmoplegia occurred. The course of the illness was therefore quite unlike poliomyelitis.

Dr. Gale rightly draws attention to the care taken by manufacturers of canned food. The tongue which came under suspicion in this instance was canned in South America.—I am, etc.,

London, W.1. DAVID KENDALL.

Inspection of Coarctation of Aorta with a Thoracoscope

SIR,—Under the heading of Medical Memoranda in the *Journal* of August 6 (p. 317) there was a report from Mr. J. R. Belcher and Dr. F. E. de W. Cayley of a case of direct inspection of coarctation of the aorta with a thoracoscope, in which they stated that there had been no previous description of a coarctation of the aorta seen through a thoracoscope or the use of this instrument as a means of identifying abnormalities of the great vessels in the thorax.

In August, 1947, a female patient aged 31 had been referred to me with a view to having Smithwick's thoraco-lumbar sympathectomy performed for hypertension. She had been married for eight years and had three children. She had been told that her blood pressure was high during her second pregnancy four years previously. Her present symptoms were referable to her hypertension, the blood pressure being in the neighbourhood of 225/110 mm. Hg when taken in the left arm. These symptoms had been present for about three years, and consisted mainly of palpitations of the heart and breathlessness on exertion, with throbbings in her throat. She had never had any headaches. Examination of her nervous system did not reveal any abnormality, but an early "silver wire" appearance was noted in the arteries of the ocular fundi. The patient's heart was somewhat enlarged, and there was a systolic murmur, best heard at the mitral and pulmonary areas. Marked pulsations were noted in the arteries of both posterior triangles of the neck, in the axillae, and at the back between the scapulae. The blood pressure in the right thigh was only 140/110 mm. Hg. Skiagrams of her chest were taken by Dr. B. P. Anderson Stuart, who reported that the aortic knob was present but that he could not detect any shadow of the aortic arch behind it, nor of the descending aorta. There was definite notching of the under-margins of many of the ribs, and radiologically the appearance was pathognomonic of aortic coarctation.

In order to be certain of the diagnosis and to determine whether the patient should be submitted to operation for this condition or not, in view of her age, it was decided to "let down" the lung on the left side by performing artificial pneumothorax on three occasions. Thoracoscopy was then carried out by inserting a Jacobeus thoracoscope through the fourth intercostal space at the anterior axillary line. The lung was seen to be collapsed and a huge subclavian artery noted, into which the arch of the aorta seemed to terminate. The internal mammary artery and the upper three intercostal arteries were seen to be about three times their ordinary size. As the lung was not completely collapsed, the descending portion of the aorta could not be seen, but the stricture appeared to be just beyond the origin of the left subclavian artery. The patient did not suffer any ill effects from this procedure and the lung expanded in a few days.

As I had had no experience with this operation, and as no other surgeon in Sydney at the time had had any either, it was decided not to advise any surgical measures then. Her case was subsequently discussed with Dr. O. T. Claggett, of the Mayo Clinic, and in view of the appearances seen at thoracoscopy and the age of the patient he stated that he would not advise any surgeon to operate on this patient as his first case. The position was fully explained to the patient and her relatives, and she is still leading a fairly normal existence and her symptoms have not progressed.

This thoracoscopy was actually performed on September 3, 1947, in the department of neurosurgery at the Royal Prince Alfred Hospital, Sydney, where the full records of the case are available.—I am, etc.,

Sydney. R. A. MONEY.

The Acute Throat

SIR,—I was very surprised at Dr. Thomas Anderson's reply (November 19, p. 1179) to the criticisms of his article on the acute throat. From the point of view of the clinician surely his own clinical observations must count for something. I agree that the majority of sore throats are mild and tend to subside naturally, but I am sure that many practitioners have seen these mild throats, treated them with aspirin, etc., and then have seen them, say, two or three days later very much worse. In these cases we have lost valuable days. The incidence of peritonsillar abscess in my practice has fallen enormously over the last few years, and I can only account for this by sulphonamide therapy instituted early on.

I would like to know just what preparation of sulphonamide was used by Dr. French in the investigation on scarlet fever mentioned by Dr. Anderson. I know that some similar researches were done with sulphanilamide years ago but have not been repeated with the recent and better preparations.

The majority of G.P.s do not make a positive diagnosis of *streptococcal* tonsillitis. There are other bacteria which are responsible for sore throats—e.g., pneumococci and staphylococci—and many strains of these organisms are amenable to the recent sulphonamides.

So far as the necessity of treating mild tonsillitis at all arises, I feel that the mild cases rarely come to the doctor at all. Would Dr. Anderson still agree that milk-borne tuberculous infection should be permitted because of the immunity it may produce? Surely if we have a potent weapon we should use it.

As regards drug rashes, these also can be caused by aspirin as well as the sulphonamides. Of polyarteritis nodosa I can say nothing, never having seen a case, but I certainly have not heard of any great increased incidence from my colleagues.—I am, etc.,

Dagenham, Essex. J. FINER.

SIR,—Dr. T. Anderson, in his excellent article on "The Acute Throat" (October 15, p. 860), repeats the traditional advice for the treatment of throat infections—"the administration of aspirin powder, which is allowed to melt slowly in the mouth before swallowing." The implication is that aspirin taken in this manner exerts its analgesic effect both locally and centrally. Dr. Anderson mercifully omits any reference to the common

but futile practice of gargling with a suspension of aspirin powder before swallowing it. The pain and irritation caused by the powder coming into contact with an already inflamed mucous membrane are the exact opposite of the effect intended—unless the intention be to bring about rupture of a peritonsillar abscess without surgical intervention by causing bouts of violent coughing. Is there in fact any evidence that aspirin exerts its analgesic effect by virtue of a local, as well as a central, action?—I am, etc.,

Kuala Lumpur, Malaya. G. SCLARE

Failed Forceps

SIR,—May I support the view of Mr. W. P. Hirsch (November 19, p. 1179) about the importance of transverse arrest of the head in difficult forceps deliveries? The so-called "persistent occipito-posterior position" is in most cases a transverse arrest of the head. Some figures which I am at present preparing for publication show that in forceps deliveries the transversely arrested head is far more common than the persistent occipito-posterior position and carries a much higher foetal risk. In the real occipito-posterior position a deliberate face-to-pubes delivery can and should be carried out in most cases, and the foetal risk is low, as a relatively safe cephalic grip is obtained with the forceps.

Mr. Hirsch rightly points out that there is quite inadequate mention of this position in the standard textbooks in this country. It is usually looked upon as an occipito-posterior position in which incomplete rotation has taken place. Mr. Hirsch mentions, however, that the head enters the brim in the transverse diameter in 40% of cases, and some American radiological studies indeed place the figure at 60% or more. If the transversely arrested head is not an occipito-posterior position, and in the majority of cases never has been one at any stage of labour, surely these two complications should be separated, especially as their treatment is so different.

The classical operation in these cases is that of manual rotation. I believe, however, that not only is this usually impossible but that attempts to carry it out are dangerous. The fault in these cases is not that the head has failed to rotate but that it has failed as a result of pelvic deformity to reach that level at which rotation normally occurs. The use of the Kielland forceps in these cases is highly satisfactory with practice, as deep general anaesthesia is unnecessary. A cephalic grip is obtained, and there is a minimum of manipulation. Spontaneous rotation usually occurs during descent.—I am, etc.,

Middlesbrough BRYAN WILLIAMS.

SIR,—Many years ago I attended a lecture on forceps deliveries in persistent occipito-positions and was amazed at the number of different theories and treatments suggested in the discussion that followed. Not being convinced by any one of these, I looked up all the available literature and found that practically the only agreement in the various descriptions was that the cause of the persistent occipito-posterior position was insufficient flexion of the head.

As a student I was taught to treat the cause of any condition, not the result. I have, therefore, since that time treated all my persistent occipito-posterior cases by flexion of the head. This is very easy to do with three fingers on the occiput, and as soon as the head starts to flex rotation takes place. This has been verified by the many house-surgeons and general practitioners to whom I have explained it.—I am, etc.,

Bristol. MABEL F. POTTER.

Sudden Obesity and Psychological Trauma

SIR,—The interesting report on three cases of "sudden obesity and psychological trauma" by Drs. H. J. Shorvon and John S. Richardson (October 29, p. 951) prompts me to ask for a very pertinent information which is lacking in the case histories. Is there a familial (hereditary) tendency to obesity in these three patients? If so, the interpretation of the pathologic mechanism involved would require some modification.—I am, etc.,

Los Angeles JULIUS BAUER.

An Unusual Murmur

SIR,—The following case history may be of interest to your readers, as it presents unusual and remarkable features.

A medical practitioner, aged 27, while sitting on a chair engaged in conversation, was suddenly seized with an attack of pain in the praecordium. The character of the pain was that of an ache, it passed from the praecordium to the inferior angle of the left scapula It was not very severe, but some five minutes later it became worse and changed its character to that of an acute sharp pain, which at times seemed to involve the left shoulder-joint. So severe was the pain at this stage that the patient decided to rest for a while in his bedroom. On arriving at his room he lay on the bed and, taking his stethoscope, listened to his heart. He heard a distinct clicking noise, and for a moment thought that the bell of the stethoscope was hitting against one of his shirt buttons. This was not the case. The noise was coming from his chest. He called for a servant, who fetched his assistant, who arrived after about 10 minutes. By this time the noise was so loud that it could easily be heard without a stethoscope; now however it was not clicking in character but harsh It was systolic in time, and absolutely regular. It would fail with every extrasystolic intermission, and return with every normal systole (the patient has had extrasystoles for years). At this point the patient noted that the pain was not continuous but throbbing. It too came with every systole, and failed during the extrasystolic intermissions. Thus the pain, the noise, and ventricular systole occurred together. A remarkable feature was that suddenly, and for no apparent reason, the noise would stop, only to return after an interval of about ten to twenty seconds. During these periods the heart sounds were normal.

Examination at this stage revealed a normal blood pressure, a heart rate of 80, and an apex beat which was strong and in its normal position. Apart from the peculiar noise, which by now could be heard some 12 ft. (3.5 m.) from the bed, and the pain there was nothing else abnormal discovered. Next day the pain had disappeared. The patient was examined by a surgeon, who excluded diaphragmatic hernia, and by a physician, who suggested as a diagnosis haemopericardium, pericarditis, or coronary thrombosis. On the next day various radiological examinations were performed, but no abnormalities were discovered except for a slight increase in the size of the left ventricle. An E.C.G., B.S.R., and blood count were performed: the E.C.G. showed extrasystoles, otherwise everything was normal Another physician was called to the case, and coronary thrombosis was diagnosed. Three days after the onset of the attack the noise disappeared.

On returning home the patient spent one month in bed, during which he felt well except for an occasional ache over the heart, and at times a sharp pain in the left elbow where the ulnar nerve crosses the medial epicondyle. After his month in bed the patient arose and on his second day up he had another attack, exactly as the first but not so severe. It disappeared after three days. The patient then saw another physician, who said that while he could not make a diagnosis he could exclude coronary thrombosis; he added that the heart was in no way at fault. On his advice the patient returned to work. Since then there have been two or three minor attacks, but so slight were they that it was not necessary for the patient to discontinue his work. Mediastinitis, with mediastinal emphysema, was the patient's ultimate diagnosis.

St. Matthews Hospital, South Africa F. A. WARD.

Malignant Tertian Malaria

SIR,—With regard to Sir Philip Manson-Bahr's letter on the subject of malignant tertian (subtertian) malaria (November 5, p. 1044) I fail to see why criticism of textbook teaching on the subject should be regarded as "betrayal of truth." It is no reflection on early observers of malaria to suggest that they did not reach finality in the matter of symptomatology and diagnosis any more than they did in the matter of treatment and other aspects of the disease. For instance, the textbook I mentioned (October 22, p. 930), and most others, twenty-five years ago was teaching that it was necessary to take large amounts of quinine over long periods to cure a simple attack of malignant tertian malaria, a belief which presumably was also not arrived at "in a day," but which has been found to be fallacious since then.

The view of M.T. malaria as being an extremely "protean" disease—a great imitator of other diseases—which I believe has been emphasized by Sir Philip more than anyone else, is no more sacrosanct. My contention is that experience in the

Tropics in the past twenty to thirty years has proved it to be capable of modification, to say the least of it. The emphasis has shifted from credulity to scepticism about very unusual behaviour on the part of M.T. malaria. There has been a general increase of knowledge about malaria as well as other tropical fevers, knowledge of its epidemiology and immunology, particularly in relation to native races. Laboratory methods have improved. All this has had its effect on the clinical approach to M.T. malaria. Nowadays a native with M.T. parasites in his blood and pneumonic symptoms is not likely to be labelled "pneumonic malaria," when it is appreciated that most members of his tribe and district carry M.T. rings in their blood as part of their normal equipment, so to speak. It is surely not unreasonable to suppose that early textbooks and descriptions of the disease might have been affected by lack of this kind of knowledge.

Any views I have put forward would not be found at all remarkable or heretical by scores of practitioners in the Tropics to-day. They are, moreover, not based on "flitting" experience, but on twenty years' recent residence in malarious districts of Kenya, as good a "pitch" for observing the behaviour of the disease, I would think, as anywhere else.—I am, etc.,

Craven Arms, Shropshire. P. ROSS.

Angioneurotic Oedema Caused by a Wasp-sting

SIR,—We feel that the following account of angioneurotic oedema consequent on a wasp-sting may prove of interest, and we would welcome advice or comments with reference to the case.

The patient, a man of 48, in good health, received a sting on the scalp from a wasp. He informed the medical officer, who was in the same room at the time, and as an erythema of the face and neck was already developing he was given 75 mg. of "benadryl." He returned to his work and began to notice a marked irritation in his legs, moderate dyspnoea, and huskiness of the voice. From then onwards the condition progressed rapidly, his dyspnoea became pronounced, and he could only speak in a whisper.

When next seen by a medical officer (about 20 to 30 minutes after the original sting) he was markedly cyanosed and had urgent dyspnoea. His face, lips, fauces, tongue, and glottis were oedematous, his conjunctivae suffused, and his eyes watering copiously. He had clinical evidence of pulmonary oedema, and his respirations were "bubbling" in type. There was a uniform erythema of his body, and scattered urticarial weals were present in his skin. His pulse was 120 per minute and of a very poor volume. He could just speak in a husky whisper, and complained of a constrictive pain across the lower part of his chest and gross skin irritation.

The condition was treated by an immediate subcutaneous injection of 8 minims (0.5 ml.) of liq. adrenalin, followed by 1 minim (0.06 ml.) per minute thereafter. By the time 16 minims (1 ml.) had been given his symptoms were improving sufficiently for him to be moved from a chair to a couch. A marked limb tremor of a coarse type had developed at this time, and continued at intervals for 1½ hours. During the course of the next few hours he was given further subcutaneous injections of adrenaline (2 minims) at about 30-minute intervals, and also a further 50 mg. of benadryl and, later, "antistin."

He fell into a deep sleep, the respiratory obstruction having been dramatically relieved by adrenaline, and by evening (approximately eight hours later) had little in the way of abnormal physical signs other than a persistent oedema of the uvula, which was causing some retching. A further 4 minims (0.24 ml.) of adrenaline helped to relieve this. By the following day he was sufficiently well to return to light duty, his duties being of a sedentary nature.

The interest of this case lies in the fact that the patient had sustained a sting on the left ring finger three weeks previously. This was apparently from a bee, as the sting had to be removed from the skin. The reaction that followed this was entirely local, consisting of an oedema and urticaria of the dorsum of the hand and of the lower third of the forearm. This settled in about three days with benadryl, rest, and local treatment. The patient gave a history of always reacting rather severely to insect bites. He has been stung only once before by a wasp (on his foot); this was some years previously.

It would appear that in the present instance the initial bee-sting provided a sensitizing dose, and during the three weeks' interval hypersensitivity developed, the second sting (though apparently from a different type of insect) being the "shocking" dose. It is interesting in this connexion to note that there was no local reaction to the second sting, the manifestation being entirely of a general nature.

An alternative explanation is offered by the work of Feldberg and Kellaway,[1 2 3] who showed that certain bacterial toxins and snake venoms which damage tissues may cause histamine to be liberated when they are perfused through the lungs. As in this case the two stings were almost certainly from two different insects, the one a bee and the other a wasp, it is possible that some toxin in the sting of the latter caused a histamine reaction in the body. Otherwise one must postulate that there is a specific protein common to wasp- and bee-stings, or that the original sensitizing dose was the sting sustained on his foot some years ago.

The problem which clearly presents itself is that of possible prophylactic treatment. Whitby[4] states with reference to anaphylaxis following serum therapy that "it is as well to assume that all individuals become hypersensitive ten days after the injection of any foreign serum and remain so for the rest of their lives." Presumably in our patient there is hypersensitivity to some protein associated with the insect's sting, and in the event of it not being possible to desensitize him, as seems more than likely, the only alternative would appear to be for him to be constantly armed with a hypodermic syringe and some adrenaline if and when he is not near to medical aid and for him to be instructed how to inject himself should the need arise.—We are, etc.,

The Natural History of Asthma

SIR,—I feel that many of your readers must have shared my feeling of disappointment in the article entitled "The Natural History of Asthma" by Drs. Elsie O. Williams and G. E. O. Williams (October 22, p. 897). From the title I had, I think not unreasonably, expected to find therein the answers to at least some of the perplexing questions presented by this disorder. It was not clear to me whether their article was in fact based on a review of medical records or whether they had taken histories from, examined, and treated these patients themselves. If they have personal knowledge of these cases, it seems to me inexplicable that they have not been struck more forcibly by certain aspects of the natural history of asthma which have been widely described in the medical literature, and which have seemed to me inescapable. If, on the other hand, their paper was based solely on the examination of medical records, I submit that the natural history of any disease, and in particular any psychosomatic disease, cannot be adequately described by such a method.

I am primarily interested in the psychosomatic aspects of asthma, and I do not feel that this has been adequately dealt with in this paper. Asthma is only one symptom which occurs in individuals who through heredity or constitution exhibit the allergic diathesis. This diathesis manifests itself not only through the familiar somatic disorders, such as asthma, hay-fever, eczema, etc., but also through a particular personality pattern and the tendency to develop specific neurotic behaviour patterns. That such personality patterns and their associated neuroses occur in allergic subjects has been shown in the writings of many authors, notably French and Alexander[1] on asthma, Wittkower[2] on hay-fever, and Rogerson[3] on the asthma of childhood.

As long ago as 1913 Marcinowski[4] wrote the following, "Only the method of psycho-analysis, however, has enabled us to come nearer to the essential nature of asthma and see the absurdity of the old [*sic*] clinical distinction between bronchial and nervous asthma. The various successes of somatic therapy do not in any way argue against the psychogenic concept. The pedagogic value of other procedures, such as breathing exercises, can be denied as little as the sedative value of drug therapy by narcotics. But in the future we shall consider as the true causal therapy only the treatment of the basic anxiety hysteria." For my own part, I would not be prepared to go so far in dogmatism as Marcinowski, for I consider the allergic factor in the aetiology of asthma as beyond doubt. I

do believe, however, that the symptoms of the majority of cases, though commencing as allergic phenomena, are gradually replaced in part or in whole by neuroses of the anxiety type.

Rogerson[1] stated in his article on the asthmatic child that there was an unusual quality in the relationship between the child and one or both of the parents. I subscribe to this view, but I feel that the effective parent in the relationship is usually the mother. Asthmatic children are abnormally dependent on their mothers, who in their turn are abnormally over-anxious about the asthmatic child. That this is a special relationship between the mother and the asthmatic child is demonstrated by the fact that such mothers do not appear to be over-anxious about the siblings, and may indeed treat them with a scant regard which is beneficial to their mental health. A quite extraordinary relationship develops between the mother and the child, in which she suffers from anxiety and the child from asthma. So long as he remains the centre of the stage he appears to remain free from anxiety, but should the position of pre-eminence, largely achieved through his asthma, be threatened he will respond with either anxiety or, what is now an established conditioned reflex, the asthmatic attack. Gradually a situation develops between the child and his mother in which the child values his special relationship so much that he finds it impossible to surrender it in order to achieve his ultimate needs.

I have found it valuable in these circumstances to approach the problem primarily through an attempt at resolving the maternal neurosis, for I have found that if the mothers can achieve insight into their psychological position *vis-à-vis* the child their anxiety may be lessened and their treatment of the child modified with beneficial results. I feel that this simple therapy should preferably be carried out by the physician who has charge of the case, and that only more complex cases require expert psychiatric treatment. It could be argued that the physician may find the time required a limiting factor. If this is so, recourse might be made to treatment on group lines. Sixteen or so mothers would form a convenient group which could be introduced to the simpler psychological aspects of asthma and allowed latitude to discuss their problem in personal terms. I would further suggest that the first group meeting may be profitably devoted to the question of the physical over-protection to which asthmatic children are subjected. Any physician who is acquainted with an asthma clinic will recognize the unfortunate child in three woollen vests, pullover, overcoat, and scarves, who looks out of place in midsummer amongst his more suitably attired fellows. It should then be a simple matter to introduce the psychological over-protection.

One further feature of asthma which, it appears to me, was inadequately dealt with in the paper under discussion is its episodic nature. Many children appear to "grow out" of asthma. I think it remains unknown why there should exist such wide variation in this respect, but it has been in my experience a striking feature of the disorder. It is because I feel that these important considerations should not be overlooked when we consider the natural history of asthma that I have presumed on your valuable space.—I am, etc.,

Gangrenous Intussusception in Childhood

SIR,—Dr. D. J. Conway and Mr. R. L. G. Dawson (November 19, p. 1153) describe two cases of gangrenous intussusception treated by the Mikulicz method. Although both cases were brilliantly successful the authors mention certain disadvantages: (1) wasting; (2) excoriation of the abdominal wall; and (3) further operative procedures for closure. In order to obviate these I would most strongly advocate the manœuvre first suggested by Woodhall.[1] This consists in making a side-to-side anastomosis between ileum and colon just above the exteriorized gut. This adds little to the time of the operation and leads to a much smoother recovery.

I have recently done this in two successful cases and found that 90% of the intestinal contents was passed per rectum. This meant that there was very little dehydration with all its attendant difficulties in the infant and only slight excoriation around the wound. In addition, subsequent closure was easier than after the simple Mikulicz procedure.—I am, etc.,

Chemistry of Trace Elements

SIR,—It has long seemed to me surprising that so little work has been done on the micro-chemistry of the rheumatic disorders. Yet we have much evidence to show that the trace elements, in excess or in deficiency, are important in many human and animal diseases in this group.

I have just read a note on cobalt poisoning, from which I learn that the toxic effects are attributed to interference with tissue metabolism due to fixation of sulphhydryl groups. It has been noted that the administration of cysteine lessens this toxic effect. A similar beneficial effect from the use of cysteine or of sulphur has been noted in rheumatoid arthritis. Clinical improvement occurs, coinciding with an increase in the cysteine content of hair and nails.

I have tried to find out whether the distribution of cobalt in the soils of this country coincides with that of rheumatoid arthritis. Hitherto I have been unable to get the necessary information. I do nevertheless suggest that investigations on these lines might prove fruitful, not only in reference to cobalt but also to many other trace elements.—I am, etc.,

Splenic Puncture

SIR,—I was interested to read of Dr. E. Tuckman's method of splenic puncture (November 12, p. 1112), as it is almost exactly like the one I used in India for the diagnosis of kala-azar, except that I kept the plunger of the syringe withdrawn while removing the needle. This caused the splenic pulp to spatter into the barrel, which was then washed down with a millilitre or so of isotonic saline into a small tube and spun at a low speed. Thick smears were made of the deposit and stained by Simeon's method.

It was my experience that when parasites were scanty the spleen was more likely to reveal them than the sternal marrow. It was very important, though, to make a prolonged search for Leishman-Donovan bodies if other findings are suggestive. I remember particularly the case of an Anglo-Indian in whom marrow examination revealed no parasites, but a single Leishman-Donovan body was found in two of three thick smears of his splenic pulp.—I am, etc.,

Ashford, Middlesex. C. F. ROSS.

Paraffin Pneumonia

SIR,—I am prompted by Dr. M. Gelfand's article on paraffin pneumonia (November 19, p. 1151) to recall a case of an East African soldier who was under my care in a military hospital in Egypt in 1946.

A man of 24 was brought in as an emergency. He was in a deep coma. There was a total flaccid paralysis. No physical signs could be found in the respiratory system. Urine N.A.D. I noticed a strong smell of paraffin in the breath of the patient, and on inquiry among his tent mates it became clear that he had been drinking a fair amount of paraffin taken from his hurricane lamp and mixed with lemonade. A gastric lavage was carried out, and he was placed *in an upright position*. Within 24 hours he was conscious and his neurological signs had subsided. He then developed a high temperature and a productive cough. There were no definite physical signs in the chest, but the radiograph showed widespread broncho-pneumonic patches of "snowstorm" type His sputum was repeatedly negative for tubercle bacilli. A course of penicillin was given, following which he made an uneventful recovery, and the *x*-ray appearances became normal within a week.

This case would correspond to group 3 in Steiner's classification (*Amer. J. Dis. Child.*, 1947, 74, 32).—I am, etc.,

London, S.E.13. G. Z. BRETT.

Painful Experiments

SIR,—Most of us in the profession, myself included, have probably at some time or other derided the charges of cruelty made by antivivisectionists against the experimenters in our ranks. It has been the custom to ease our consciences, probably in genuine belief, by dismissing the charges as the outpourings of cranks who in any case were not aware that painful experiments were conducted only on the anaesthetized animal.

Within recent years, however, there has been genuine cause for disquiet, and the experiments on conscious rats described under the section headed "Effect of the Alarm Reaction" in the paper appearing in the opening pages of the *Journal* of November 19 (p. 1129) must surely arouse misgivings in the minds of some of us who were given to scoff.—I am, etc.,

Leighton Buzzard, Beds. M. C. ROTHCOPE.

Infestation with Trichostrongylus

SIR,—I have just read Dr. Ian S. Stewart's article (October 1, p. 737) on trichostrongylus infestation. I now believe this infestation to be a common disease among the Mauritians recruited into the British Army. I have kept no records, but treat about one case of "hookworm" a week. Personal experience in the examination of stools has convinced me that many more cases pass unrecognized through my hands. One may examine a stool carefully for over half an hour and find one ovum just as the search is being given up after numerous slides have been examined. And several stools may be negative before an ovum is found.

With one exception none of these men has been anaemic. Their symptoms have been abdominal; had they been otherwise stools would probably not have been examined. They were all treated with tetrachlorethylene and oil of chenopodium. No adult worms were recovered after treatment, though ova seemed to disappear, at least for a while. They were then discharged from hospital.

In one case adult worms were recovered after treatment. This man had a haemoglobin of less than 3 g., and subsequently recovered completely. In this case numerous ova had been found in the stools and their development into larvae had been typical. In the other cases ova were scanty and fully segmented. Their development neither resembled that of *Strongyloides* ova nor of *Ankylostoma*—certainly not the former.—I am, etc.,

Benghazi D. HAMILTON.

Death by Hanging

SIR,—When a malefactor was hauled up to the bough of a tree the presumption is death was by strangulation, although pressure on the jugular veins causing cerebral congestion may have induced unconsciousness before death supervened. A similar anaesthesia was induced before disembowelling in the sentence of hanging, drawing, and quartering.

But about a century ago the questions Dr. F. A. Richards (November 26, p. 1235) asks and the misgivings he feels—whether or not any of the rest of us share his ideas—arose for the very practical reason that too many criminals were being revived after execution, even though they had been left hanging the prescribed period. It was becoming common for the friends or relatives, or even an inquisitive surgeon, to have a hackney coach ready and whisk off the body immediately it was cut down, usually to a tavern, where a vein was opened and, if any blood flowed, restorative measures were applied. From these occurrences it was concluded that the drop used, in contradistinction to the more primitive method, was too short, and the present long-drop method was substituted with the direct object of breaking the neck. The ideal; I was informed as part of my medical education many years ago, is for the odontoid peg to break the odontoid ligament and drive into the medulla, destroying the vital centres.

Reports of post-mortem findings published in accounts of inquest proceedings frequently leave in doubt whether this is achieved; but fracture of two or three of the upper cervical vertebrae is invariably mentioned. Dr. Richards's crushed cervical cord appears in actual fact to be a much more complete destruction than anything which can be quoted as an example of compression of the cord; and if an actual pulping of the medulla is not achieved it is difficult to see how the vital centres can retain any activity when there is such widespread destruction and consequent direct violent alteration of pressure just below.

One would agree that the present method, or any conceivable method, of hanging does not cause instantaneous death, because the adjective is inapplicable to any mode of death known to man; but it approaches instantaneousness much more closely than any other method, even shooting, unless in that method a bullet actually traverses the medulla. And even in such a case the wound of entry presumably causes some momentary knowledge of injury before the vital centres are destroyed. Electrocution is sometimes considered to be as quick as lightning, but it is understood that early mishaps with this method, including some arising from using too high a voltage, have led to the use of three successive shocks, and, therefore, which causes death cannot with certainty be determined.—I am, etc.,

London, S.W.6. C. T. NORRIS

The G.P. and E.C.T.

SIR,—I believe that our hospital is the only place in Cornwall where E.C.T. is applied, thus I think it almost my duty to join in the controversy started by Dr. Donald M. O'Connor, of Launceston (October 29, p. 984). The percentage of relapses among my patients during the last five years is very small, I could say negligible, though I do not deny that some needed a second course of E.C.T., and still less few a third course. With this confession I should like to combine a citation from Dr. Robert Thompson's letter (November 19, p. 1178), with whose statement I am in complete agreement. He asks, "What is wrong with a second course of E.C.T., or even a third?" Here it is worth while to state that in the U.S.A. an average course of E.C.T. has 20 shocks (not 6–10), not to mention weekly maintenance doses lasting one year and longer.

The letter of Dr. J. Ernest Nicole (November 12, p. 1116) stresses an important point. It is true that E.C.T. alone is not always a cure in itself, and after-treatment is necessary in many cases. This brings me to a fact not fully appreciated yet. It is an established fact that patients—say, with an injury of a leg and some resulting disablement—are not only given time of convalescence but also, and what is more important, rehabilitation facilities, by means of which they are taught to rely again on their injured limb. Are patients who sustained an injury to the most sensitive organ in the body—the cerebrum—not in need of and entitled to rehabilitation?

I too believe that the impact of everyday life, without gradual preparation for it, is at least one of the main causes of many relapses. Much has been done and much is done in our hospitals; nevertheless under present conditions convalescent wards in many hospitals cannot replace convalescent homes and still less rehabilitation centres. There, apart from necessary maintenance doses of E.C.T., I visualize patients being taught to rely on themselves again. The return to everyday life and to the original conditions and circumstances—often a big part in the causal mosaic—will, properly guided, be done gradually and, I think, with lasting effect even in cases which at present tend to relapse.—I am, etc.,

Bodmin, Cornwall. ERNEST E. FELDMESSER

Poisoning by Ferrous Sulphate

SIR,—May I offer a footnote to the article by Dr. J. H. Prain (November 5, p. 1019) and to your annotation (p. 1034) on poisoning by iron pills? It is desirable that not only the patient who possesses tablets of the "fersolate" type but the doctor also who prescribes them should be aware of the danger.

In a recent case, when a child of 14 months swallowed 44 tablets, the practitioner was consulted within five minutes and again after an hour and a half: he said that there was no danger and that the baby would be perfectly all right. At the inquest he regretted his error, with the explanation that the tablets were

not listed in the textbooks as a poison, and no antidotes were recommended for an overdose. The makers' container itself, of course, bears a warning; it should be remembered that a pharmacist supplying them on prescription does so in a plain packet.—I am, etc.,

HENRY PORTER

POINTS FROM LETTERS

Asthma at Sea

Dr. G. L. ALEXANDER (Bristol) writes: It is commonly assumed that a voyage to the Antipodes is wholly good for health. Many find to their cost that this is not so, noticeably asthmatics on the large crowded liners. The first night out from Tilbury they are smitten with the worst attack they have ever had. This does not respond to their usual remedy, repeated large doses of adrenaline being required for even partial relief; and it is days before recovery is complete. On arrival at the Australian coast, down they go again, and they have a bad time crossing the Bight. Some have nearly died. Practitioners would do well to advise their asthmatic patients bound for Australia to fly if they can afford it; otherwise to consult the ship's surgeon as soon as they get aboard, as there are various ways in which he can help them.

Treatment of Rheumatic Fever with Antihistamine Drugs

Dr. L. A. QUIRK (London, W.1) writes: It is over two years ago that I first used the antihistaminics in a case of rheumatic fever—apparently with good results. I tried them in a second case, and again was impressed favourably. Later I was informed by a physician at a Vancouver (British Columbia) hospital that pyribenzamine was used routinely in cases of rheumatic fever admitted to that hospital. . . . As it would appear that theoretically the antihistaminics are the logical treatment for rheumatic fever, and because of the importance of this disease in general practice, may I urge you to let us general practitioners have some information on the results of investigations at an early date?

Confusion with Tablets

Mr. B. A. LEVINSON (London, W.1) writes: From the patient's standpoint I have frequently noted with apprehension the absence of warning or even identifying marks upon barbiturate and other dangerous tablets. A recent incident prompts me to address you on the subject. My doctor prescribed pethidine and "amytal." My chemist supplied them, each box being marked, in the words of the prescription, "to be taken as directed." How was I to know which was which? I guessed, and guessed wrongly. The chemist, to whom I went for identification, took a little time himself to distinguish between the two. . . . I do not intend any expression against either doctor or dispensing chemist, but I venture to suggest to physicians that when prescribing such tablets they should add a direction to the chemist to mark the container with the name of the contents or some other adequate indication of their nature.

Firework Injuries

Mr. F. KEITH HAYMAN (Sharnbrook, Bedford) writes: Having read Mr. L. A. H. Snowball's letter (November 26, p. 1236) may I suggest a very simple safeguard? A conspicuous "A" or "U" could be printed on the firework or, if too small, on a strong tab firmly attached to it, thus conforming to the already well-known cinema-film classification. An obligation could be laid on the manufacturers to mark their products in this way, and on shops to sell only "U" fireworks to children. This could easily be arranged by Government regulation, if the suggestion could be conveyed to the right quarter.

Health and the Soil

Dr. ANGUS CAMPBELL (Edinburgh) writes: I was very interested to read the letter (November 19, p. 1178) by Dr. G. T. Wrench entitled "Health and the Soil." My late teachers at Edinburgh, George Lovell Gulland, Professor of Medicine, Edinburgh, and Sir Edward Sharpey-Schafer, Professor of Physiology, Edinburgh, both described the work of Sir Robert McCarrison, and predicted that the work which he had begun would lead to very great changes in the lives and health of the people. These lectures are now some thirty years old, and very little seems to have been done in the way of following out this great work. It is difficult to see why this great work has not advanced as far as its merits indicate, but the secret seems to lie in the one word "fragmentation." Dr. Wrench describes the answer admirably as the "interdependent whole." To be fair to the Minister of Health one must admit that he is trying to spread the idea of healthy living rather than the bottle of medicine and that he follows out this idea by encouraging action. But I agree with Dr. Wrench that by concentrating on the present ailments of the people we will never reach perfect national health.

Obituary

JOHN ORR, M.D., F.R.C.P.Ed.

Dr. John Orr, who died at Edinburgh on November 28 in his 79th year, was for 21 years dean of the School of Medicine of the Royal Colleges in Edinburgh, where he taught the class of materia medica up to 1945. He was educated at George Watson's College, for which he retained a high affection during his whole life, being twice president of the Watsonian Association. He qualified M.B., Ch.M with honours from Edinburgh University in 1891, and in 1896 took his M.D. and was elected a Fellow of the Royal College of Physicians of Edinburgh. He chose general practice as a career, and after a long and busy life retired nearly 20 years ago. He was then free to devote his interest and energy to medical education and teaching, in which he had always been greatly interested. To gain wider experience and insight into these subjects he visited medical schools in the U.S.A., Canada, and India. He became dean of the School of Medicine of the Royal Colleges in Edinburgh in 1924. He was a member of council of the Royal College of Physicians of Edinburgh from 1926 to 1930, and acted as their representative on the board of managers of Edinburgh Royal Infirmary. He was a former senior president of the Royal Medical Society of Edinburgh. Dr. and Mrs. Orr celebrated their golden wedding early this year, and great sympathy will be extended to his widow.

Lieutenant-Colonel A. D. Stewart writes: By the death of Dr. John Orr in his 79th year the medical profession of Edinburgh has lost a very distinguished member—and not only the medical profession. Like many other doctors he had wide interests and activities outside his chosen career. He had a deep knowledge and appreciation of classical music, and he took a lively interest in the provision of symphonic music in Edinburgh. He was a keen and expert bowler and curler, and he had a real love of Classical and English literature. His administration of the School of Medicine of the Royal Colleges of Edinburgh was particularly successful, and it was largely due to his interest and ability that the school came successfully through difficult periods until it was taken over by the University in 1943. His interest and kindness and ready help will be remembered by many generations of students. He gave long and devoted service to the board of managers of the Royal Infirmary of Edinburgh, on which he served for over 20 years. The department of radiology strongly interested him, and he was largely responsible for the development of this important and essential side of the hospital's activities. The secret of John Orr's success lay in the sterling qualities of his mind and character. It is given to few men to live as long and as complete a life as his. Nature had gifted him with good health and an abundance of physical and mental energy, a clear reasoning mind, an acute intellect, and a cheerful and optimistic outlook on life. He had as a foundation a simple but high religious faith, and from this sprang many of the qualities of his character. Dr. Orr will be remembered by us as a great servant of the Royal Infirmary, as an outstanding example of one who used to the full the opportunities afforded by the voluntary principle to serve unselfishly and unstintingly a great voluntary institution, and through it a whole generation of his countrymen. Those who knew him and shared his friendship will remember him as one who was kindly, courteous, and wholly sincere.

Dr. JAMES DEWAR, who died on September 1, was born at Mullingar, in Southern Ireland, on November 22, 1883. His father was the late Elliot Paxton Dewar, Head Inspector of Schools in Ireland. James Dewar was educated at Lurgan College and at Queen's College, Belfast, where he graduated in 1907. In 1911 he came to Bury as assistant to the late Dr. France. In the first world war he served as medical officer to the 5th Battalion Durham Light Infantry, returning to Bury in 1919. He then took over the practice of Dr. France, one of the biggest in Bury, and carried it on until his death. He was police-surgeon to the county borough from 1919 to 1948. The cares of a large industrial practice allowed him little leisure, and latterly his only hobby was the collection of antiques. In his younger days he was interested in rugby, cricket, and rowing. James Dewar's charm of manner endeared him to all his many patients. His industry enabled him to carry on the large practice to which he had succeeded. His loyalty to his medical colleagues, his unassuming modesty, and his native Irish wit were notable. He died, as he would have wished to die, in harness, but he will long be remembered.

The Rev. Dr. GEORGE BROCKLESBY DAVIS died in Cambridge on November 5 at the age of 76. Dr. Davis was the son of the Rev. Brocklesby Davis, and was born in Allahabad in 1873. He was educated at Corpus Christi College, Cambridge, and later at Ridley Hall, where he read for Holy Orders. As a student of the London Hospital he qualified in 1904. After taking a curacy at Forest Gate he joined the Church Missionary Society in 1905, and from then until 1919 he served as a medical missionary at Amritsar, in India. He was in charge of the C.M.S. Hospital at Amritsar for many years, and he served many of the outlying village hospitals and dispensaries also. At the same time he continued his ministry as a priest of the Church of England in the little mud churches scattered over a wide district. Early in his career in India he learnt from the famous Colonel Smith the intra-capsular technique of cataract extraction, and he performed hundreds of operations on Sikh and other patients. He was also responsible for an extensive programme of inoculation against plague, and he taught scores of Indian dressers and dispensers minor medical and surgical procedures. Dr. Davis, perhaps on account of his equable temperament, was always known to his Indian patients as "Firishta Doctor Sahib," which means roughly "Angel Doctor." In 1911 he married the daughter of the Rev. Charles Howard. When he returned to England in 1919 Dr. Davis brought his wife with him and the first five of his subsequent family of eight children. He was in practice in Ely for 25 years, for most of them in partnership with Dr. K. S. Maurice-Smith. In 1931–3 he was chairman of the Isle of Ely Division of the B.M.A. He was medical officer and public vaccinator for Ely, Trinity, and Little Downham, and medical officer to the Ely Dispensary and Poor Law Institute. His health broke down in 1945, and thereafter he was partially paralysed and lived in retirement in Cambridge. He was much loved by the people of Ely and was never known to refuse to answer a call from the Fens, even in the worst weather. He was an able general practitioner and a skilled obstetrician, and he will be remembered as a man who gave invaluable service to the community in which he worked, both in India and in Ely.

Dr. WILLIAM BRANDER, who died on November 21 in London at the age of 73, graduated M.B., Ch.B. at Aberdeen in 1901. He proceeded M.D. with the highest honours in 1910 and Ch.M. with distinction in 1922. He took the M.R.C.P. in 1937. He served in Firvale Hospital, Sheffield, then a Poor Law hospital, for some years before becoming medical superintendent of Hackney Hospital in 1911. This post he held until October, 1929, when he was appointed principal medical officer in charge of the general hospitals division of the London County Council. He retired from office on account of ill-health in 1936. Soon after his retirement he went to Egypt. He was still there at the outbreak of war and was unable to return. Throughout the war years and for the early post-war period he wandered over eastern Africa, from Egypt to the Cape and back again, in an unavailing search for a climate that would suit him and relieve his bronchitis and emphysema. In due course, after the war, when transport became available and when he was well enough to travel, he returned to this country, but from the time of his return his health was such as to enforce on him a quiet and retired life. His absence in Africa for so many years and his seclusion after his return took him out of public life and away from professional contacts. Every period is in a sense a transitional period, but it fell to Brander in exceptional measure to deal with rapid changes and developments. He was at Hackney during the years after the first world war when many of the Poor Law hospitals made rapid advances in response to the increasing demands which were being made on their services. Hackney Hospital under Brander was in the forefront of these changes. Then with the Local Government Act of 1929 the London County Council assumed control of the Metropolitan Asylums Board hospitals and also of all the hospitals in London formerly controlled by the twenty-five Boards of Guardians. It was quite a big job to take over the M.A.B., but the M.A.B after all was already an organized hospital service. It was Brander's task to deal with hospitals, mostly general, which had been under twenty-five different managements, hospitals varying in size, in function, and in development. He was also concerned with epileptic colonies and nurseries and his duties included the administration of the district medical work, which until 1948 played such an important part in the medical care of the poorest people of London. He was responsible, too, for the supervision of the medical services in the Public Assistance Institutions. Brander bore the brunt of this stupendous task. He worked very hard and there is little doubt that this contributed to his ultimate breakdown in health. Without Brander's help Sir Frederick Menzies would have found very much more difficult the task, which he carried out so well, of moulding and developing the municipal hospital service of London. Dr. Brander's academic distinctions indicate his intellectual quality, and his clinical experience was exceptionally wide. He was a very good all-round doctor. It is true that much of his professional time was devoted to administrative problems, but he was a better and a wiser medical administrator because he had been first of all a good doctor. The interests of the patient were always his first interest, and it is noteworthy that he was especially concerned that the chronic sick should receive proper care and consideration. Brander was indeed a canny Scot—his opinions were formed slowly and hesitantly but once formed were always sound, and his advice was highly valued. As a man he was friendly, sympathetic, and generous, a charming companion and a loyal and helpful colleague. His loss will be mourned by all who worked with or for him. He leaves a widow who has devoted herself to his care, especially since his breakdown in health, and a son who is a banker in North Africa.—A. D.

Dr. WILLIAM MURRAY CAIRNS died on November 28 at his home in Wallasey at the age of 83 years. The son of a Liverpool cotton broker, he was born in that city in 1866 and educated at the Liverpool Institute and Edinburgh University. He qualified in 1891 and graduated M.D. in 1915. Shortly after qualifying he was for a time surgeon in charge of the English Presbyterian Mission Hospital in Formosa. He returned to Liverpool in 1896, where he established himself in practice and also took a great interest in local medical affairs. Dr. Cairns was a life member of the Liverpool Medical Institution, which he joined in 1897. During his membership he held the offices of secretary in 1919–21, vice-president in 1922–3, and he was made a trustee in 1922. He took a great and active interest in the work of the St. John Ambulance Association, being county surgeon to the Brigade and also chairman of the Liverpool Centre. During the 1914–18 war he was medical officer in charge of the St. John auxiliary military hospital in Liverpool. His services were recognized by the conferment of the C.B.E. in 1920, and ten years later he was made a Commander of the Order of St. John of Jerusalem. Among his other appointments was that of specialist medical officer to the local education committee in regard to the examination of physically defective children, and he was also an examiner in medicine to the General Nursing Council. He had been a member of the

'SULPHAMEZATHINE'
TRADE MARK

ORAL SUSPENSION FOR CHILDREN

For many bacterial infections in children, 'Sulphamezathine' brand Sulphadimidine is the safest and most effective of all the sulpha drugs. It rarely gives rise to unpleasant symptoms, and renal complications are almost unknown.

'Sulphamezathine' Oral Suspension is a palatable orange-flavoured preparation containing 1 gramme of 'Sulphamezathine' per 2 fluid drachms. Children take it readily, and it provides an attractive alternative to 'Sulphamezathine' tablets.

'Sulphamezathine' Oral Suspension is issued in bottles of 100 c.c., 500 c.c. and 2 litres.

THE INTRAVAGINAL TAMPON IN MENSTRUAL HYGIENE

An important clinical study

No. 3

Original Gynaecological and Obstetrical Research. Annual Report.

Tampax were given to 36 normal menstruating women, and they were instructed to insert one Tampax night and morning during and between their menstruation; that is, twice every day for one year. Vaginal mucosal biopsies, pH, bacterial flora, and glycogen contents of the vaginal mucosa were taken before, during, and after Tampax were used. To our surprise, the vaginal mucosa became much hypertrophied; the pH became more acid, which is helpful; the glycogen was increased and the bacterial flora was also improved. Tampax are made of cotton, and that is the reason they cause no harm, but produce a more healthy vagina.

Ten cases of senile vaginitis were instructed to insert one Tampax night and morning, and the vaginal mucosa in these cases became markedly hypertrophied. The alkaline vagina became acid and the reaction in the vagina became like that where estrogenic hormones had been used.

The normal non-pregnant vaginal mucosa also became so hypertrophied in some cases that it appeared like that of a pregnant woman. The vagina also became dried and appeared healthier than it was normally.

COTTON PACKS AND NORMAL MENSTRUATION

Tampax were used as successfully as perineal pads in 95 per cent of our 45 research cases. They were changed about as often as the pads. The psychological aspect of menstruation is in many cases relieved when the belt is no longer used. There was no blocking of the menstrual flow in the cervix in any of these cases.

Reprinted from the Medical Record and Annals, Houston, Texas, U.S.A., May, 1941

LEUCORRHOEA VAGINAL

Keeps the vagina dry. A dry method. In long standing cases of leucorrhoea where the patients have to wear a perineal pad almost all the time to keep the underclothes from becoming soiled, a Tampax will absorb the secretion and keep the vagina very dry. You will have won her confidence and then proper treatment can be instituted.

TAMPAX

SANITARY PROTECTION WORN INTERNALLY

Literature and samples of both absorbency sizes will gladly be sent on request.

MEDICAL INQUIRIES: TAMPAX LTD., 110 JERMYN ST., S.W.1

British Medical Association for the past 46 years, and up till recently he took an active part in its work.

Dr. E. S. A. Ashe writes: I was surprised to see that among all the appreciations of the late Professor T. P. McMurray (November 26, p. 1236) no mention was made of the fact that he was not only a brilliant orthopaedic surgeon but a brilliant general surgeon as well. I had the honour to be his house-surgeon, and my wife also, and we have vivid recollections of how on more than one occasion he would turn round at the end of a long operation list of orthopaedic cases and operate on a case of acute intussusception which had been brought in as an "emergency." It was fascinating to watch those surgically beautiful hands one moment wielding an osteotome to shiver a bone and the next, by the most gentle pressure, reducing the seemingly irreducible intussusception. Of McMurray it might be truly said: "He was a man who went about doing good and healing all manner of sickness."

Medico-Legal

LIBEL ACTION BY MR. MATTHIAS ALEXANDER

In March, 1948, an action for libel was brought by Mr. Frederick Matthias Alexander, of London, against three medical men: Dr. Ernst Jokl, Physical Education Research Officer to the Union Education Department, Dr. E. H. Cluver, Director of the South African Institute for Medical Research at Johannesburg, and Dr. B. Maule Clark, of Houghton, Johannesburg, editors of *Manpower*, a biannual scientific journal published in Pretoria by the Government Printer and circulating throughout the Union. The evidence in this case was reported at length in the *Journal* of March 20, 1948 (p. 575), and the written judgment of Mr. Justice Clayden was summarized in the issue of May 8, 1948 (p. 909). Mr. Alexander was awarded £1,000 damages and costs because of an allegedly defamatory article which appeared in the March, 1944, issue of *Manpower*. The defendants entered an appeal.

Judgment on Appeal

Dismissing the appeal with costs,[1] the Chief Justice said that because the trial court had found that it had not been proved that Mr. Alexander's system was entirely worthless, counsel for the appellant doctors had sought to use the evidence of the trial for the purpose of showing dishonesty on the part of Mr. Alexander. The sting of the defamatory matter which had to be justified was that Mr. Alexander knew that his technique was of no value to improve health or cure ill-health, and that he practised it dishonestly to exploit the rich. But, in view of the considerable body of evidence from medical practitioners and others who deposed to benefits derived by patients from his treatment, it was not possible to find that he knew that his technique was worthless and that he only used it to impose upon and exploit the rich.

Passing to the plea of fair comment, the Chief Justice said that there could be no fair comment upon facts which were not true. Counsel for the appellants relied upon the plea of fair comment only in respect of the passage in the offending article dealing with appendicitis. In that passage it was suggested that Mr. Alexander claimed to be able to cure acute appendicitis by means of his system, and the comment was that to give this type of advice was criminal. But the fact was that Mr. Alexander did not, in his books, claim that he could cure acute appendicitis.

As to the contention that in any event the damages awarded to Mr. Alexander by the Transvaal Provincial Division of the Supreme Court were excessive, the Chief Justice said that Mr. Alexander was entitled to compensation for his injured feelings and the hurt to his dignity and reputation. His reputation, in this case, included not only his good name from a moral and social point of view, but also his reputation as a teacher of his system of psycho-physical education. He was therefore unable to come to the conclusion that the damages awarded to Mr. Alexander for that injury were excessive.

[1] *Cape Argus*, June 3, 1949.

Medical Notes in Parliament

National Health Service (Amendment) Bill

The National Health Service (Amendment) Bill was read a third time in the House of Lords without debate on December 2. Consideration of the amendments made by the House of Lords in this Bill was set down for December 8 in the House of Commons.

The Nurses (Scotland) Bill

The Nurses (Scotland) Bill was considered on report in the House of Commons on November 30. On the first schedule (the General Nursing Council for Scotland) Mr. WOODBURN moved amendments to meet the wishes expressed during the committee stage that the Council should include a person with financial experience. Commander GALBRAITH thanked Mr. Woodburn for bringing forward the amendment, and it was accepted. The House then passed to the third reading of the Bill. In moving this Mr. WOODBURN said that on the committee stage he had been asked to give special consideration to the question of "fever nurse," including a nurse with tuberculosis experience. He had been unable to alter the Bill in any way, but he would take care to ensure that the members of the Nursing Council included a person with recent tuberculosis experience.

Sir THOMAS MOORE said the Bill would depend largely on its administration for its success. One of the ways by which nurses could be made happy and contented, and therefore efficient, was by the food they received. According to information from nurses who had received their training in hospitals which he would mention the food was disgraceful. That applied to Glasgow Royal Infirmary. Mr. WOODBURN submitted that the question of food in hospitals was not a question regarding training of nurses. Only training was dealt with in the Bill. If Sir Thomas had complaints of the kind which he had indicated he had better submit them to Mr. Woodburn for verification and not make a personal statement in the absence of verification.

The SPEAKER said the matter had nothing to do with the Bill.

Sir THOMAS MOORE said he did not withdraw his allegation which had been made to him by a nurse. He accepted the Speaker's ruling and would not pursue the matter further. He believed the Bill was a good one and would have all the success which the House desired it to have.

The Bill was then read a third time. It had already passed the House of Lords.

Leprosy

Mr. SORENSEN on November 15 asked what further steps were being taken to deal with leprosy in Nigeria and other West African Colonies.

Mr. CREECH JONES replied that it was not possible to estimate how much of the total expenditure on medical services was devoted to the treatment of any particular disease. No statistics existed which would show reliably whether the incidence of leprosy was increasing or decreasing in West Africa. In Nigeria there was a fully organized Leprosy Service. Arrangements were being made for this Service to extend its activities from the areas in the south, where previously its intensive operations had been carried out, to the whole territory. Missionary bodies, already extensively engaged in leprosy work, were being brought fully into the programme. An experienced leprosy research officer had recently been appointed. A comprehensive scheme for the future had been drafted and was under consideration. This scheme involved heavy expenditure. The extent to which it would be possible to implement it would depend on the relation this expenditure bore to the needs of other social services and the finances of the territory as a whole.

Mr. CREECH JONES added that in the Gold Coast there were five refuges for lepers. A full-time leprosy officer and ten lay assistants had been appointed and had taken up their duties. It was intended that three leprosaria should be established to cover the country. Each would have accommodation for 2,000 patients. Native authorities would be helped to establish leprosy villages where the inhabitants would lead a normal life

under medical supervision from the nearest leprosarium. The rate of progress in implementing these proposals would depend upon the availability of medical staff of all grades, many of whom must be trained locally. In Sierra Leone a permanent form of organization for the control of leprosy was being planned. The co-operation of the Evangelical Brethren United Mission and the British Empire Leprosy Relief Association had been assured, and a grant had been made from the Colonial Development and Welfare funds. In the Gambia plans for the reorganization of Leprosy Services were well advanced. These included the construction of a new Government leprosarium, which would function as a training centre for local staff and also serve as a valuable instrument in propaganda. In both Sierra Leone and the Gambia progress was at the moment hampered by the difficulty of obtaining suitably qualified staff.

Calories

Mr. STRACHEY stated on November 21 that for the year ended last June the calorie figure for the United Kingdom was 2,980 per head per day, which, he said, was not significantly different from the pre-war figure of 3,000 calories per head per day. He added that the figures for the present rate of consumption might prove to be above the pre-war figure by a significant number of calories. He agreed that once up to the pre-war figure the calories had a limited significance and that variety and quality of food came in as important factors. Distribution was more equitable than it had been before the war. Consumption of fats was 98% of pre-war, of eggs 91%, of cheese 110%, of bacon 49%, and of liquid milk 157%. These figures did not include the recent increase in the bacon ration.

Pneumoconiosis in South Wales

In the House of Commons on November 24, opening a debate on Welsh affairs, Mr. JAMES GRIFFITHS said that the Silicosis Board no longer suspended a man with pneumoconiosis unless that disease was accompanied by tuberculosis. Diagnosis of the disability could now be made at a much earlier stage. The Board could, and did, recommend that men could continue in underground employment in approved conditions, subject to re-examination at intervals of not more than 12 months. This was an improvement on the old system by which men were given a certificate once, after which nobody bothered. It was too early to say the new scheme was successful, but it was encouraging. Steady progress was also being made in the application of methods of dust suppression. Dr. Fletcher and his team, in consultation with the Silicosis Board and the Pneumoconiosis Research Unit at Llandough Hospital, Cardiff, were conducting research into the diagnosis and treatment of the disease and into rehabilitation. The future of the South Wales coalfield depended on pneumoconiosis being overcome. Experiments in certain of the North Wales slate quarries in laying dust, particularly in the slate-splitting sheds, showed encouraging results.

Restricted Use of Operating Theatres

Colonel LIPTON and Mr. SWINGLER asked questions on November 24 about the reported restriction of the use of the operating theatre in a hospital or hospitals to the hours 9 a.m. to 5.30 p.m.

Mr. BEVAN said he was making inquiries.

Colonel LIPTON asked whether Lord Horder had not yet had the courtesy or the courage to substantiate the allegation which, in the absence of supporting evidence, would be regarded as irresponsible and possibly malicious.

Mr. BEVAN said he had made inquiries, and so far as he could find out the Ministry of Health had received no information whatever from Lord Horder before or since he made his statement.

The SPEAKER said that Colonel Lipton's supplementary question was an attack on a member of the House of Lords and should not have been made. There was no need in the question to mention any name.

Mr. BEVAN pointed out that the statement had been made by a member of the House of Lords but not in his capacity as a member.

The SPEAKER said that a very offensive supplementary question had imputed malice and that it was not in order for questions to be offensive.

Mr. BEVAN asked leave to point out that the original statement complained of was exceedingly offensive.

Mr. SWINGLER asked Mr. Bevan to consult with the Law Officers of the Crown to find out whether hospital administrators as a group could be protected in any way from unsubstantiated charges against unspecified hospitals.

Mr. BEVAN replied that the only defence and protection which administrators had, or, indeed, which the country had, lay in questions and answers in the House of Commons and in the publicity which was given to them.

Mr. WILSON HARRIS asked whether it was unreasonable that what might be termed routine operations should be confined to set hours provided that emergency operations could take place at any hour.

Mr. BEVAN said there were many inquiries to be made and there were thousands of hospitals. In the absence of detailed information he now had to circularize all the hospital management committees. Certainly it was perfectly reasonable for operating theatres to be closed during certain hours if they were always available for emergency operations, but the implication which had been raised was a reflection upon the National Health Service.

Mr. HENRY STRAUSS asked whether it was not premature until Mr. Bevan had completed the inquiries promised by him in his original answer, to say whether the charge under discussion was substantiated or not.

Mr. BEVAN said that a responsible person, if he had thought that what he alleged was being done and was wrong, would have written to the Minister and given the name of the hospital in order that the Minister might make inquiries. Instead of that much anxiety, pain, and alarm had been unnecessarily given to many hundreds of thousands of people.

Replying to another question by Mr. SWINGLER, Mr. BEVAN said no instruction had been issued either by him or by any regional hospital board to any hospital to reduce the use of penicillin on the ground of expense. The matter was one entirely at the discretion of the doctor.

Mr. SWINGLER suggested that Mr. Bevan should courteously request a member of the House of Lords either to substantiate or to have the common decency to withdraw his allegation.

Mr. BEVAN said he did not propose to enter into any communication with the noble lord in this matter. If the noble lord would send him the precise information upon which he had based his very serious allegation Mr. Bevan would have inquiries made. In the absence of such information Mr. Bevan said he could only ask the country to take no notice of such irresponsible statements.

Mr. NICHOLSON said that some people were allergic to penicillin and that the administration of it did them harm. He asked whether any steps were being taken to see that doctors did not administer it when the patient told them that he was allergic to it.

Mr. BEVAN said that this was entirely a clinical matter with which he did not propose to interfere.

State Grants for Medical Students—On November 17 Mr. HASTINGS asked how many medical students were in receipt of scholarships and maintenance grants provided by the State and local authorities respectively, in England and Wales now and in 1938. Mr. TOMLINSON replied that 3,071 awards by his department to medical students were current, of which 2,634 were under the "Further Education and Training Scheme." The comparable figure for 1938 was 29, all of which were State scholarships. He was unable to state how many of the awards by local education authorities were for medical students.

Chloromycetin.—On December 1 Mr. ROLAND ROBINSON asked why chloromycetin was no longer available to patients under the National Health Service in cases where it was prescribed by their doctors. Mr. BLENKINSOP explained that, to ensure that this scarce and expensive drug was used to the best advantage, Mr. Bevan had arranged to purchase all available supplies and to distribute them through regional hospital board centres. The boards had discretion to make supplies available through the distribution centres to practitioners in domiciliary practice in exceptional cases.

Leprosy.—Mr. TOUCHE on December 1 asked how long the St. Giles Home near Chelmsford had been used for the treatment of lepers, and whether during that period any cases had arisen of this disease being contracted by people in the neighbourhood. Mr. BLENKINSOP replied that the home had been used for 35 years and that no cases of local infection with leprosy were known.

Hearing-aids.—Dr. BROUGHTON asked on December 1 how many Medresco aids had been issued. Mr. BLENKINSOP replied that, to November 5, 39,159 patients in England and Wales had been supplied with Medresco aids. The current average rate of issue was 1,015 a week. Waiting-lists totalled about 86,000. He added that Mr. Bevan was arranging for the staffs of the distribution centres to be increased and new centres to be opened as soon as possible.

Morphine for Mountaineers.—Mr. EDE told Mr. MARPLES on December 1 that representatives of mountaineering interests were invited some time ago to discuss with officers of the Home Office and of the Health Departments how suitable arrangements might be made for the administration of morphine to injured climbers. Mr. Ede hoped that a meeting would be arranged in the following week. He promised to announce his decision as soon as possible after this meeting.

School Dentists.—Mr. TOMLINSON stated on December 1 that for a complete service of dental inspection and treatment it is estimated that a ratio of about one dentist to 3,000 children would probably be required. In January, 1949, the number of school dentists employed by local authorities was equivalent to 868 whole-time officers. To give a ratio of one dentist to 3,000 children, an additional 975 would then have been required. Since then, there were indications that the number had seriously decreased.

Tuberculosis.—Sir ERNEST GRAHAM-LITTLE asked Mr. Bevan whether he was aware that, out of all the patients diagnosed during any one year as suffering from pulmonary tuberculosis, approximately 70% received institutional treatment in public sanatoria, and some 60% would have died from tuberculosis during the following five years. On December 1 Mr. BEVAN replied that he was not sure that an up-to-date long-term follow-up of patients would bear out Sir Ernest's figures. In any case the best hope of making curative treatment more effective lay in detecting the disease in its earliest stages. This was being increasingly achieved through mass radiography and supervision of contacts.

Tuberculosis Beds.—Answering Sir ERNEST GRAHAM-LITTLE on December 1, Mr. BEVAN reported that about 4,400 beds in sanatoria and tuberculosis hospitals were unoccupied on December 1 for lack of staff. Nursing staff in these institutions increased in the year ended June 30 by 774 full-time and 319 part-time, and in the same period 652 beds were reopened.

Hearing and Speech Defects.—The numbers of children suffering from hearing defects and speech defects noted at school medical inspections during 1948 were approximately 19,000 and 20,000 respectively. Ancillary part-time instruction in speech and lip-reading is desirable for some of these children and is provided by some local education authorities.

Epileptics.—The number of persons in epileptic colonies in England and Wales at the end of October, 1949, was 2,604.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on November 19 the degree of D.M. was conferred on W. B. Matthews (in absence).

UNIVERSITY OF CAMBRIDGE

In a Congregation held on November 26 the degree of M.D was conferred on P. Hugh-Jones.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—P. B. B. Gatenby, W. Houston.

M.B.—*B. A. McC. Thompson, *E. G. England, *Gwendoline G. L. Poots, W. D. H. Powell, Mildred Vilensky, E. V. Page, D. Miller, Marisa A. O'Keeffe, J. H. Ashmore, Margaret B. E. Ellis, F. H. Moore.

B.CH.—L. J. Clein, O. H Killen, Evelyn Browne, J. H. Ashmore, Ruth M. Perrott, Joan I. Buchanan, F. A. Walkey, E. G. England, R. C. Gray, Vyvyan I. K. Johnston, E. B. McHugh, R. ff. Jackson, T. T. E. Michael, B. J. O'Reilly, E. V. Page, Sheilagh M. McHugh, Margaret B. E. Ellis, W. A. McGaw, R. N. Siberry, W. D. McNaul

*With second-class honours.

UNIVERSITY OF LONDON

The University Court has re-elected Sir Henry Dale, O.M., F.R.S., as Deputy Chairman for 1949–50.

The following have been appointed or nominated for appointment or reappointed as representatives of the University on the governing bodies indicated in parentheses: Professor W. C. W. Nixon (Council of the Training College for Midwife Teachers); Dr. G. H. Newns (Hospital for Sick Children); Dr. A. Hope Gosse (Hospitals for Diseases of the Chest); Dr. J. C. Hawksley (University College Hospital).

Joseph Rotblat, D.Ph., has been appointed to the Chair of Physics tenable at St. Bartholomew's Hospital Medical College, from January 1, 1950.

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *Guy's Hospital Medical School:* Dr. T. A. B. Harris, Dr. W. S. McConnell, and Dr. E. H Rink (Anaesthetics); Dr. T. H. Hills (Radiology); Dr. R. Kauntze (Medicine); Mr. R. S. Lawrie (Surgery); Mr. T. L. T. Lewis (Obstetrics and Gynaecology); Dr. R. C. MacKeith (Children's Diseases); Mr. J. W. Mansie, M.R.C.S., L.R.C.P., F.D.S. (Dental Surgery); Dr. T. A. Munro (Mental Diseases). *King's College Hospital Medical School:* Dr. F. S. Cooksey (Physical Medicine) *St. Bartholomew's Hospital Medical College:* Dr. G. J. Cunningham (Pathology (Morbid Anatomy and Histology)). *St. George's Hospital Medical School:* Mr. H. F. Anderson (Surgery); Dr. D. C. Shields (Physical Medicine). *St. Thomas's Hospital Medical School:* Dr H. J. Wallace (Dermatology); Dr. W. D. Wylie (Anaesthetics) *London School of Hygiene and Tropical Medicine:* Dr. J. A. Fraser Roberts (Hygiene and Public Health (Medical Genetics)); Dr. R. F Tredre (Hygiene and Public Health (Tropical Hygiene)). *University College:* Dr. J. Joseph (probationary recognition for two years from July, 1949) (Anatomy).

The Sanderson-Wells (Senior) Prize, of the value of £20, has been awarded to Dr. S. S. B. Gilder for his essay on "The Symptoms and Signs of Experimentally Induced Vitamin Deficiencies in Man," and the Sanderson-Wells (Junior) Prize, of the value of £10, has been awarded to D. F. Hawkins (University College) for his essay on "The Relation of Dietary Factors to Man's Performance of Muscular Work."

University Studentships in Physiology and in Anatomy have been awarded to R. J. Shephard (Guy's Hospital Medical School) and J. I. S. Robertson (St. Mary's Hospital Medical School) respectively

Applications are invited from members of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus. Applications, which will be considered three times a year, must be submitted by March 31, July 31, and November 30 Forms of application and further particulars may be obtained from the Academic Registrar Senate House, London, W.C.1.

UNIVERSITY OF MANCHESTER

The Queen has graciously consented to visit the University on the occasion of the centenary celebration of the foundation of Owens College in May, 1951. Her Majesty will on that occasion be presented for an honorary degree. The date of the ceremony has not yet been agreed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A series of lectures on otolaryngology, arranged jointly by the Royal College of Surgeons of England and the Institute of Laryngology and Otology, began at the College (Lincoln's Inn Fields, London, W.C.) on December 1, when Professor Geoffrey Jefferson discussed intracranial abscess. The remaining lectures will be delivered on the first Thursday in January, February, March, May, and July, 1950, at 5 p.m., and are open, without fee, to Fellows and Members and Fellows and Licentiates in Dental Surgery of the College. Details will be printed in the "Societies and Lectures" column of the *Journal* for the appropriate weeks.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Dr. C. H. Andrewes, F.R.S., will deliver the Dr. John Burns Lecture in the Hall of the Faculty (242, St. Vincent Street, Glasgow), on Wednesday, December 14, at 5 p.m. His subject is "The Common Cold." Medical practitioners are invited to attend.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following were admitted to the Fellowship of the College on December 2: W. G. Fegan, J. H. Johnston, W. R. Lamb.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 19. [No. 46

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Stillbirths	158	25	18			222	27	29		
Rate per 1,000 total births (including stillborn)			21					32		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

Notifications in the week ended November 26 were: poliomyelitis 176 (219), polio-encephalitis 17 (7). Figures for the previous week are shown in parentheses. The number of notifications of poliomyelitis and polio-encephalitis together is now a little higher than it was in the corresponding week of 1947—193 against 145. An extension of relatively high prevalence into the winter months has been reported from other countries of recent years, and when the next review of the world situation is published by WHO it will be interesting to see how far this trend is a general one.

Multiple cases were reported in the following counties: London 24 (29), Berks 3 (5), Buckingham 5 (3), Chester 6 (0), Derby 2 (1), Devon 2 (1), Dorset 3 (1), Durham 2 (2), Essex 16 (14), Gloucester 8 (8), Hereford 2 (1), Hertford 6 (4), Kent 14 (20), Lancaster 10 (10), Leicester 7 (3), Middlesex 11 (15), Norfolk 12 (3), Nottingham 5 (4), Southampton 4 (3), Stafford 3 (2), East Suffolk 3 (2), Surrey 6 (6), East Sussex 3 (4), Warwick 7 (13), West Yorks 17 (32), Glamorgan 5 (10).

Contacts Travelling to and from Eire

When a person who is under surveillance because he is suspected of having been in contact, either abroad or in this country, with a case of smallpox, cholera, typhus fever, plague, or yellow fever intends to travel to the Irish Republic, the medical officer of health who is responsible for the surveillance should send a notification direct to the Department of Health, Custom House, Dublin. If it is necessary to send a notification by telegram it should be addressed to "Health Dublin."

When a person who is under similar surveillance in the Irish Republic intends to travel to this country, the city or county medical officer of health who is responsible for the surveillance there will send, or if necessary telegraph, such a notification to the Ministry of Health (Division 5C), Whitehall, London, S.W.1. The Ministry will notify the medical officer of health for the district to which the person is travelling. For the time being these arrangements are restricted to the five diseases named—those to which the International Sanitary Conventions apply—but the possibility of extending them later to other infectious diseases is not excluded.

Discussion of Table

In *England and Wales* infectious diseases were more prevalent than during the previous week. Increases in the number of notifications included: scarlet fever 400, measles 246, acute pneumonia 133, dysentery 24, whooping-cough 14, and diphtheria 11. The only exceptions to the general rise were acute poliomyelitis and acute polio-encephalitis with decreases of 7 and 16 respectively.

The incidence of scarlet fever is now at its highest level for six years. During the week additional cases were reported from every region except Yorkshire; the largest local rises were Lancashire 100, Derbyshire 40, Warwickshire 35, and Middlesex 34. The incidence of measles declined slightly in the southern section of the country and rose in the northern, though it was only in a few counties that a large rise occurred. In the combined areas of London, south-east, south-west, and south-midland counties the notifications of measles were 76 fewer than in the preceding week, while the largest increases were Durham 147, Norfolk 127, and Staffordshire 45. The chief feature of the returns of diphtheria was a rise of 6 in the notifications in Lancashire. The local fluctuations in the trends of whooping-cough were small; the largest was a decline in notifications of 31 in Lancashire. A small rise in the notifications of acute pneumonia was fairly general throughout the country; the largest increases were London 34 and Yorkshire West Riding 27.

Of the 27 cases of typhoid, 10 were notified in Lancashire. The largest centres of dysentery were Lancashire with 29 notifications (Liverpool C.B. 12), Glamorganshire (Cardiff C.B. 17), and London 10. The largest reported outbreaks of food-poisoning were Dorset, Sherborne U.D., with 39 cases and Yorkshire West Riding, Batley M.B., with 29.

POLYCREST

ANTIPRURITIC CREAM

THE "VICIOUS CIRCLE" OF PRURITUS

In the past in the treatment of pruritic conditions counter-irritants were employed, which merely superimposed pain on itching. To-day it is realized that antipruritic therapy can only be effective if it is not only curative but also breaks the 'vicious circle' of itching —scratching—infection—more itching—and so on.

A CAUSAL AND SYMPTOMATIC THERAPY

This modern approach to the problem is embodied in Polycrest Antipruritic Cream, which combines the high bactericidal and fungicidal properties of Phenylmercuric Nitrate with the prompt and prolonged surface anaesthetic action of Amethocaine and Benzocaine, thereby affording simultaneous causal and symptomatic therapy.

INDICATIONS

Pruritus Ani, Haemorrhoids, Anal Eczema, Diabetic Pruritus and other pruritic conditions of diverse origins, including Tinea Infections.

FORMULA:

Phenylmercuric Nitrate	..	*0.25%*
Amethocaine	..	*0.50%*
Benzocaine	..	*5.00%*
Cream Base	..	*q.s.*

A NEW DIFFERENT ANTIHISTAMINIC PROVIDES

Up to 24 hours of Relief

Results are similar to those above in all studies—this distinctly different Abbott compound, DI-PARALENE, is outstanding in its long duration of action. While most antihistaminics must be administered 5 to 6 times daily, DI-PARALENE need be administered only once or twice daily in most cases. The degree of relief with DI-PARALENE is equal or better, and in many cases there are fewer side-effects. When DI-PARALENE is given at bedtime, relief may be obtained throughout the night. In most cases no additional dosage is required until the next bedtime. The average adult dose is 50 to 100 mg. once daily, or 50 mg twice daily. Since the onset of effect may be from about one to two hours, it may be desirable in some cases to administer one dose of a quicker-acting antihistaminic with the initial dose of DI-PARALENE. DI-PARALENE is available in 50-mg. tablets in bottles of 100. Try it in your next case of allergy. Write for literature to ABBOTT LABORATORIES, LTD., WADSWORTH ROAD, PERIVALE, MIDDLESEX.

A&H

I-SO-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk, through absorption of water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetes.

It is valuable also in mucous colitis, dysentery, hæmorrhoids, and intestinal flatulence. After the performance of colostomy, I-so-gel gives excellent results by solidifying the fæces.

ALLEN & HANBURYS, LTD. LONDON, E.2

in Circulatory Dysfunction

'PADUTIN,' an extract from the pancreas, has a selective action on peripheral circulation. Administration of this hormone produces dilatation of the peripheral blood vessels, with increased blood flow, limb volume and surface temperature. There is no appreciable effect on the blood pressure.

'Padutin' is of benefit in intermittent claudication, Raynaud's and Buerger's disease, and in faulty circulation giving rise to acrocyanosis and chilblains. Among the packings listed below the 10 ml. bottle will be found particularly convenient.

AFRICA HOUSE, KINGSWAY, W.C.2 HOL. 8730

In *Scotland* increases were recorded in the notifications of acute primary pneumonia 43, scarlet fever 16, and diphtheria 9, while a decrease of 12 was reported for whooping-cough. The rise in diphtheria was contributed by Glasgow, where the cases rose from 12 to 26. Of the 79 cases of dysentery 54 were notified in Glasgow.

In *Eire* falls occurred in the number of notifications of measles 29 and diarrhoea and enteritis 8, and a rise of 13 was recorded for scarlet fever.

In *Northern Ireland* rises occurred in the number of notifications of scarlet fever 83, whooping-cough 22, and measles 18. The rise in these three diseases was due to an increased prevalence in Belfast C.B.

Week Ending November 26

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,827, whooping-cough 1,035, diphtheria 121, measles 1,469, acute pneumonia 710, cerebrospinal fever 32, acute poliomyelitis 176, acute polioencephalitis 17, dysentery 144, paratyphoid fever 11, typhoid fever 11, food-poisoning 128.

Medical News

Nuffield Grants for Cortisone Research

The Nuffield Foundation has made a grant to Oxford University of £10,000 payable over three years for research on the synthesis of cortisone, and the following grants, also payable over three years, to Cambridge University: (1) £5,000 for research in the Chemical Laboratory under Professor A. R. Todd, F.R.S., on the convenient synthesis of peptides and their application in particular to problems of the adrenocorticotropic hormone, and for work on the synthesis of compounds with cortisone activity but simplified structure; (2) up to £11,000 for research in the School of Biochemistry under Professor F. G. Young, F.R.S., on pituitary adrenocorticotropic hormones.

Royal Society Elections

At the 287th anniversary meeting of the Royal Society, held on November 30, the following were elected as officers and council for the ensuing year. *President:* Sir Robert Robinson, O.M. *Treasurer:* Sir Thomas Merton. *Secretaries:* Sir Edward Salisbury and Sir David Brunt. *Foreign Secretary:* Professor E. D. Adrian, O.M. Sixteen members of council were elected, including the following medical men: Professor G. L. Brown, Dr. F. M. R. Walshe, Dr. V. B. Wigglesworth, and Professor S. Zuckerman.

World Health Organization Fellowships

The World Health Organization, in order to strengthen health services throughout the world, provides fellowships to medical practitioners who are engaged, or will be engaged, in public health services, medical education, or medical research. The amount of the fellowships varies from 200 to 300 dollars a month, plus cost of travel, tuition fees, books, and literature. The fellowships are open to members of the medical profession who have gained at least two years' experience in the field in which they will study under the fellowships scheme. In special circumstances consideration will be given to undergraduates and to non-national graduates employed by the governments of countries not possessing their own graduates suitable for fellowships, provided that such fellows agree to return at the end of their period of study in order to serve the country whose government sponsored their fellowship. Full details of the fellowships can be obtained from the General Secretary, United Nations Organization, Palais des Nations, Geneva.

Sheriff

Mr. E. Davies-Thomas, of Edgbaston, Birmingham, has been nominated a sheriff for Cardiganshire for 1949.

Dr. Morris Fishbein

According to *Time* of December 5, Dr. Morris Fishbein has now resigned from the editorship of the *Journal of the American Medical Association*. He has been editor since 1924.

No Health Centre for Festival

Early in the year the London County Council decided to erect a comprehensive health centre on a site in East India Dock Road, Poplar, in an area to be used for the purposes of the Festival of Britain, 1951. It was intended to give visitors to the Festival some idea of the architecture and facilities of such a unit. But the Minister of Health has been unable in present circumstances to approve of such a centre, though he has intimated that he would be prepared to approve a new building of relatively small extent to accommodate a group practice. The Health Committee of the County Council considers that a group-practice building could only be in the nature of an improvised transitional type of health centre, and as such would be hardly worthy of inclusion in the exhibition. Moreover, the erection of a group-practice building might prejudice the use of the site for a comprehensive health centre later on, and the purpose of closely associating the private practitioner with the other personal health services in the area would not be achieved. The Minister's suggestion will not therefore be adopted. The site is to be reserved until the economic situation has improved and further experience has been gained in the operation of health centres and group practice on a small scale.

Changes in Nurses' Examinations

The General Nursing Council for England and Wales has decided to make certain changes in its Preliminary and Final examinations held in June, 1950, and subsequently. The time allotted to the practical and oral examinations in nursing will be increased, and the oral examinations in anatomy and physiology, hygiene, medicine, and surgery will be discontinued. A section on "Introduction to Psychology" will be included in Part 2 of the Preliminary examination syllabus, and there will be optional questions on psychology in the papers for Part 2 of the Preliminary examination in June, 1950, and thereafter. Candidates for Part 2 of the Preliminary examination in October, 1951, and subsequently must have been instructed in the section on "Introduction to Psychology." The introductory instruction on psychology should teach the student to understand behaviour as it is affected and modified by changes in the environment and the body, by family and community influences, education, and so on. The council does not consider it desirable that instruction should be given on the investigation and diagnosis of abnormal conditions or on psychological methods of treatment.

Wills

Professor Stevenson Lyle Cummins, formerly of the Welsh National School of Medicine, left £8,804. Dr. Arthur Carveth Johnson, of Newport, left £13,697; Surgeon Rear-Admiral William Wallace Keir, of Bishop's Waltham, Hants, £3,676; Dr. Brian Rait-Smith, of St. Albans, Herts, £3,526; and Dr. Richard Aloysius Quinn, of Wigton, Cumberland, £2,820.

COMING EVENTS

Heberden Society

The annual general meeting of the Heberden Society will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., to-day and to-morrow (Friday and Saturday, December 9 and 10). On December 9, at 5 p.m., the annual general meeting will be followed by the Heberden Oration on "Classical Gout" by Professor F. Wood Jones, F.R.S., and at 8 p.m. the annual dinner will be held. On December 10, at 10.30 a.m., at St. Thomas's Hospital (Anatomy Lecture Theatre), London, S.E., Professor D. V. Davies will open a discussion on "Anatomical Aspects of the Rheumatic Diseases," and at 11.45 a.m. the discussion will be continued by Dr. W. A. Fell.

National Society for the Prevention of Blindness

The next annual conference of the National Society for the Prevention of Blindness will be a combined meeting with the Pan-American Association of Ophthalmology, to be held on March 26 to 30, 1950, at the Hotel Floridian, Miami Beach, Florida. Among the topics to be discussed at the conference are current blindness prevention programmes in the countries of the Western Hemisphere; trachoma; industrial ophthalmology; eye problems of school-children; and medical and social management of the glaucomas.

American Tuberculosis Meeting

The 46th annual meeting of the American National Tuberculosis Association will be held on April 24-28, 1950, at the Hotel Statler, Washington, D.C. The medical section of the association—the American Trudeau Society—and the National Conference of Tuberculosis Secretaries, an organization of public health workers, will meet at the same time. The medical sessions will be on the following subjects: the chemotherapy of tuberculosis, surgical aspects of tuberculosis, laboratory investigations, and non-tuberculous diseases of the chest. Further information may be obtained from the National Tuberculosis Association, 1790, Broadway, New York. 19. N.Y.. U.S.A.

SOCIETIES AND LECTURES

Monday

INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330-332, Gray's Inn Road. London, W.C.—December 12, 5.30 p.m., "*The Mechanism of Vestibular Reactions*," by Professor Gösta Dohlman (University of Lund, Sweden).

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W.—December 12, 8.30 p.m., discussion: "*Bone Tumours*," to be introduced by Drs. J. F. Brailsford and H. A. Sisson.

Tuesday

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 47, Queens Gate Terrace, London, S.W., December 13, 7 for 7.30 p.m., discussion: "*Fashions and the Freudians*," to be opened by Mr James Laver.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—December 13, 5 p.m., "*Scleroderma*," by Dr. G. B. Dowling.

INSTITUTE OF PHYSICS: ELECTRONICS GROUP.—At 47, Belgrave Square, London, S.W., December 13, 5.30 p.m., "*The Nervous System as an Electrical Machine*," by Dr. W. Grey Walter.

Wednesday

CAMBRIDGE UNIVERSITY.—At Addenbrooke's Hospital, Cambridge, December 14, 2.30 p.m., "*The Ethics of Medical Practice*," by Dr. B. Branford Morgan.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—December 14, 5 p.m., "*X-ray Technique*," by Dr. C. W. McKenny.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At B.M.A. House, Tavistock Square, London, W.C., December 14, 8.30 p.m., "*Diseases of the Newborn, Recent Advances in Treatment*," by Dr. Victoria Smallpeice.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Ashford Hospital, London Road, Ashford, December 14, 3 p.m., general meeting. "*Some Endemic Diseases of Egypt*," by Dr. E. N. Callum.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—December 14, 5 p.m., "*The Common Cold*," by Dr. C. H. Andrewes.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace Road, London, S.W.—December 14, 2.30 p.m., "*Tuberculosis Infection and the Use of B.C.G.*," discussion to be opened by Dr. Frederick Heaf.

SOCIAL PSYCHOTHERAPY CENTRE, 7, Fellows Road, London, N.W.—December 14, 5 p.m., "*Social Psychiatry*," general discussion by Dr. Joshua Bierer and other members of the staff of the centre.

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Burlington House, Piccadilly, London, W., December 14, 6.15 p.m., meeting of Nutrition Panel. "*Soups as Food*," papers by Messrs. H. S. Sarson and J. G. Huntley, and Miss B. R. Stanton. Visitors are invited.

Thursday

BRITISH INSTITUTE OF RADIOLOGY.—At 32, Welbeck Street, London, W., December 15, 8.15 p.m., Joint meeting with Radiological Section, Royal Society of Medicine, "*The Physical Properties and Performance of Fluorescent Materials and Amplification of the Intensity of the Fluorescent Image*," papers by Messrs. J. W. Mitchell, M.Sc., and G. N. Harding, B.Sc.

EDINBURGH CLINICAL CLUB.—At B.M.A. Rooms, 7, Drumsheugh Gardens, Edinburgh, December 15, 8 p.m., "*Varicose Veins and Thrombophlebitis of the Leg*," by Mr. T. McW. Millar.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—December 15, 4.30 p.m., lecture-demonstration: "*Neurology*," by Dr. D. J. Williams.

Friday

BIOCHEMICAL SOCIETY.—At Guy's Hospital Medical School (Department of Biochemistry and Chemistry), London Bridge, S.E. December 16, 2 p.m., communications and demonstrations.

BRITISH INSTITUTE OF RADIOLOGY.—At 32, Welbeck Street, London W., December 16, 5 p.m., meeting of Medical Members.

BRITISH INSTITUTE OF RADIOLOGY.—At Royal Society of Medicine 1, Wimpole Street, London, W., December 16, 8.15 p.m., Joint meeting with Radiological Section, Royal Society of Medicine "*The Physical Properties and Performance of Fluorescent Materials and Amplification of the Intensity of the Fluorescent Image*," paper by Mr. F. I. G. Rawlins, M.Sc.

FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., December 16 2.15 p.m., "*The Chest After Thoracic Operation*," speakers Mr P. R. Allison and Professor A. S. Johnstone.

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES MEDICAL SCHOOL Maida Vale, London, W.—December 16, 5 p.m., clinical demonstration by Dr. J. W. D. Bull.

Saturday

YORK MEDICAL SOCIETY.—At 17, Stonegate, York, December 17 8.30 p.m., "*Disorders of Micturition*," by Mr. J. K. Willson Pepper.

APPOINTMENTS

HOCKEN, M. E., M.B., Ch.B., D.P.H., County Medical Officer and School Medical Officer, Isle of Ely County Council.

JACKSON, MALDWYN ISAAC, M.R.C.S., L.R.C.P., Consultant Chest Physician Newport and East Monmouthshire Group, Welsh Regional Hospital Board.

JOHNSTON, WILLIAM, M.B., Ch.B., Medical Officer, Royal Western Counties Institution, Starcross, Devon, South-Western Regional Hospital Board.

MAXWELL, J. A., C.V.O., C.B.E., M.B., B.Ch., F.R.C.S.Ed., Surgeon Rear Admiral, R.N.(ret.), Medical Superintendent, St. Mary's Hospital, Portsmouth.

PERRY, WILLIAM RODHAM, M.B., B.S., D.P.H., Medical Officer of Health to Basford Rural District Council and Eastwood Urban District Council, and Assistant County Medical Officer, Nottinghamshire.

SCOTT, GORDON ISLAY, M.B., Ch.B., F.R.C.S.Ed., Consultant Surgeon Moray Hospitals.

WALKER, JOSEPH, M.B., Ch.B., L.D.S., D.P.H., D.P.D., Divisional Medical Officer, Health Division 4, Lancashire County Council.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Cader.—On November 30, 1949, to Joan (née Thornborrow), B.D.S., wife of Marzook A. Cader, M.R.C.S., L.R.C.P., M.B., B.S., D.L.O., a son.

Lucas.—On November 30, 1949, at Strathlean Nursing Home, Muswell Hill, to Kathleen, wife of David R. Lucas, M.B., B.S., a daughter—Jacqueline Frances.

Scudamore.—On November 24, 1949, at Stapleford, Notts, to Mary Ruth (née Jones), wife of Dr. T. O. Scudamore, M.B., D.R.C.O.G., a daughter.

DEATHS

Anderson.—On November 29, 1949, William Anderson, O.B.E., M.B., F.R.C.S. of 28, Carnegie Crescent, Aberdeen.

Cairns.—On November 28, 1949, at 60, Seabank Road, Wallasey, William Murray Cairns, C.B.E., M.D., previously of 67, Catharine Street, and Parkfield Road, Liverpool, aged 83.

Cameron.—On November 25, 1949, at Midhurst Sanatorium, Robert Cameron, M.D., of 19, Fulbrooke Road, Cambridge.

Gordon-Munn.—On November 29, 1949, at Croys, Castle Douglas, Scotland John Gordon Gordon-Munn, M.D., F.R.S.Ed., J.P., aged 86.

Grimshaw.—On October 11, 1949, at 2, Holly Bank Road, Clifton Park Birkenhead, John Grimshaw, M.D., D.P.H., aged 82.

Humphrey.—On December 1, 1949, Leslie Alfred Humphrey, M.R.C.P. M.R.C.S., aged 32.

Hutchinson.—On November 24, 1949, at 20, Ramshill Road, Scarborough Robert Hutchinson, M.B., Ch.B.Ed.

Huxtable.—On November 23, 1949, Arthur Edwin Huxtable, M.R.C.S., of The Vicarage, Houghton Regis, Beds, aged 94.

King.—On November 21, 1949, at Southampton, Arthur King, M.D., aged 87.

McKiernan.—On November 21, 1949, at Falmouth, Thomas Hugh Robinson McKiernan, M.B., B.Ch., B.A.O.

Mahood.—On November 23, 1949, Allan Edward Mahood, M.B., F.R.C.S., of Haynford, Norwich, aged 86.

Nuttall.—On November 30, 1949, at Southern Hay, Llanerch Road West Colwyn Bay, Denbigh, Harold Nuttall, M.D., aged 78.

Orr.—On November 28, 1949, at Edinburgh, John Orr, M.D., F.R.C.P.Ed., of 6, Strathearn Road, Edinburgh.

Parry.—On November 19, 1949, at Caernarvon, William Hilton Parry, M.C. M.B., Ch.B., J.P.

Reeve-Flaxman.—On November 20, 1949, at Middlesex Hospital, London, W. Samuel Christopher Reeve-Flaxman, M.R.C.S., L.R.C.P., aged 69.

Sanders.—On November 20, 1949, at Gleniffer, Four Oaks, Warwickshire Arthur Addison Sanders, O.B.E., M.B., Ch.B., Surgeon Captain R.N., retired.

Smith.—On November 30, 1949, at Springfield, Hawkhurst, Kent, Herbert Austen Smith, C.I.E., M.B., B.Ch., M.R.C.S., L.R.C.P., Colonel I.M.S. Ret., aged 83.

Smith.—On November 29, 1949, at Pembury Hospital, John Smith, M.B., Ch.B. of Sutton Valence, Maidstone, Kent, aged 48.

Storey.—On November 24 1949, on way home from Singapore, Bryan Hamilton Storey, M.R.C.S., L.R.C.P., Colonial Medical Service, aged 27.

Stork.—On November 27, 1949, after a short illness, Ernest Stork, D.S.O. M.B., J.P., of Bury St. Edmunds, aged 79.

Sullivan.—On November 23, 1949, at The Elms, South Kirkby, near Pontefract Edward James Holmes Sullivan, M.D., aged 90.

Trethowan.—On December 1, 1949, at Stoke-on-Trent, Joan Durham Trethowan, M.R.C.S., L.R.C.P.

Wilson.—On November 28, 1949, at The Lindo Wing, St. Mary's Hospital London, W., Anna Justina Augusta Wilson, F.R.C.P.Ed., late of 11, Wimpole Street, London, W.

Wyatt.—On November 24, 1949, at Guy's Hospital, Harold Douglas Wyatt M.R.C.S., L.R.C.P., of the Ministry of Pensions.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vasomotor Rhinitis

Q.—*(1) What is the modern opinion regarding the value of skin tests in a case of vasomotor rhinitis? (2) What hope is there of obtaining relief for this distressing complaint by desensitization? (3) Is cauterization of the nose of any value in treatment? The patient in question has a family history of allergy, and x-ray examination of the sinuses reveals a mucous polypus on the floor of the right antrum. (4) Could this polypus cause the symptoms, and what should be done about it?*

A.—(1) Allergy to foods and inhalants undoubtedly is the cause of some cases of vasomotor rhinitis, especially where there is a family history of allergic conditions. In this group inhalants account for the large majority and foods are relatively unimportant. Apart from pollens, which are seasonal, house dust is by far the commonest cause. In these cases morning sneezing is very common and a history of itching or irritation of the nose and nasopharynx is often obtained. The nasal smear in these cases contains eosinophil leucocytes but no pus. In such cases intracutaneous skin tests are helpful and must be done. But when skin tests are carried out by inexperienced persons as a short cut to the diagnosis and as the sole method of investigation they are more often than not misleading. Although positive skin reactions may be obtained to more than one allergen, clinically one allergen is usually found to be dominant. This can, with special techniques, be confirmed immunologically.

(2) Eliminative procedures aimed at reducing contact with house dust to a minimum together with desensitization give satisfactory results in these cases. The difficulty arises owing to the frequent development of superadded infection and the natural tendency of these patients to become allergic to their infection. The finding of pus in the nasal smear is an indication of infection. The presence of a polypus suggests that this patient has had some superadded infection to which he is allergic.

(3) Cauterization of the septal tubercle and anterior end of the inferior turbinate will in many cases relieve the symptoms. It does not, of course, remove the cause, and should not be too often repeated, as it destroys some of the ciliated epithelium.

(4) The polypus probably does not contribute appreciably to the symptoms. Removal could be effected only by opening the antrum through the canine fossa, with a risk of introducing further infection—a most undesirable complication in allergy. Therefore it should be left, unless it is growing rapidly and possibly blocking the ostium.

Treatment of Alcoholism

Q.—*What is the rationale of the treatment of alcoholism by "antabuse"? Is there a risk to the patient in the use of this drug, and also afterwards if he should take alcohol? Is this the best method of treatment available or are there any other drugs which are as effective and as easy to administer?*

A.—"Antabuse" (tetraethylthiuramdisulphide) interferes in some unknown way with the normal metabolism of alcohol in the body, giving rise to unusually high concentrations of acetaldehyde in the blood after alcohol has been taken. This causes unpleasant symptoms, such as congestion of the face and eyes, tachycardia, palpitation, giddiness, headache, and anxiety, which are nearly always alarming to the patient and are occasionally severe enough to be dangerous. In consequence it is wise for this treatment, in its early stages at least, to be undertaken in an institution until the patient's reaction to a test dose of alcohol following antabuse has been properly established. Antabuse is innocuous unless alcohol is subsequently taken. There is as yet no other sensitizing agent to alcohol which is as effective and as easy to administer as antabuse, but the latter in itself is not a short-cut to the cure of alcoholic addiction; it is only a valuable ancillary to the psychological and environmental rehabilitation of the patient, without which the ultimate results of treatment are almost always unfavourable.

Progressive Muscular Atrophy

Q.—*Has there been any recent advance in the understanding of the aetiology, and also in the treatment, of progressive muscular atrophy? What is the prognosis?*

A.—Unfortunately there has been no recent advance in the understanding of the aetiology or in the treatment of progressive muscular atrophy. The course of the disease varies considerably in different individuals, and the age of the patien seems to be the most important factor in influencing the rat of deterioration. When the disease begins in the early thirties there is usually a rapid downhill course and death often occurs within two years. In the elderly, on the other hand, the prognosis is usually better and the patient may live five years or even longer. The site at which the motor neurone degeneration begins is also important, for when the bulbar muscles are affected early the prognosis is worse than when the disease first shows itself in the wasting of the small muscles of the hands.

Tuberculosis Mortality Rate

Q.—*The death rate from respiratory tuberculosis is now only a quarter of that of 100 years ago. It would be interesting to know how much of this decrease is due to better treatment as opposed to general public health measures. Are there any figures available to show to what extent the cure rate in diagnosed cases of pulmonary tuberculosis has improved under modern methods?*

A.—This is too large a question to be answered shortly: in fact, the complete answer is not known. A number of factors have influenced the decline in the mortality rate from tuberculosis, and authorities differ in their estimates of the relative importance of these. It seems probable that improved living standards following industrialization have had the greatest influence. There is abundant evidence that changes in living conditions—for example, in wartime—are accurately reflected in the tuberculosis mortality. The campaign against tuberculosis and improvements in treatment have undoubtedly played a part, but it is impossible to assess their effect accurately. Bentley ("Artificial Pneumothorax," *Spec. Rep. Ser. med. Res. Coun., Lond.*, 1936, 215) showed that the number of patients whose lives were prolonged by artificial pneumothorax treatment was so small when compared with the whole tuberculous population that the use of this treatment would not alter materially the gross survival rates. The same applies to most other methods of treatment, which, although invaluable to a small group, have little effect upon the whole. Statistics are available to show that, within their limited field, modern methods of treatment have improved the chance of survival. Simmonds and Martin (*Amer. Rev. Tuberc.*, 1948, 58, 637) have demonstrated that the chance of survival is doubled by the use of collapse therapy in suitable cases, and the benefit to be derived from streptomycin in cases of tuberculous meningitis is even more obvious. For further discussion of the reasons for the general decline in the tuberculosis mortality rate the questioner is referred to Rich, *The Pathogenesis of Tuberculosis*, 1946, chapter 21, and Pinner, *Pulmonary Tuberculosis in the Adult*, 1945, chapter 19.

Testicular Grafts

Q.—*Is it possible to graft a testis in a case in which both testicles have been removed and, if so, is this likely to improve the general health?*

A.—Testicular grafts taken from other animals, and even from chimpanzees, are rapidly extruded by the host's body. Even when grafts are made from human testes removed because

they are misplaced, they are absorbed within a year. Fortunately there is no need to resort to grafting now that the male hormone has been discovered and synthesized. A patient can be prevented from becoming a eunuch by giving him injections of testosterone or by implanting pellets of this hormone. Under such treatment the signs of eunuchoidism disappear and sexual desire returns. Treated thus, a patient of the writer's has passed through the Divorce Courts as the guilty party and remarried. Sexual capacity has been maintained with weekly doses of 25 to 50 mg. of testosterone.

Oedema of Upper Eyelids

Q.—*Is there any treatment for persistent oedema of the upper eyelids? A boy aged 18 has suffered from this for more than four years—to such a degree that the pouches so formed hang over the ciliary margins. Renal function is normal, but skin tests show definite reaction to cow and dog hair. He had a severe tonsillitis when a child, but recent removal of the tonsils has not improved the condition. Salt-free diet, antihistamines, and specific and non-specific desensitization have had no effect.*

A.—Oedema of the upper eyelids may be secondary to inflammation, injury, systemic disturbance, or allergy. Sometimes blockage of the upper canaliculus causes oedema of the upper eyelids, but one would not expect it to persist for four years. It is unusual for allergic oedema to be confined to the upper eyelids. Since it is so persistent and constant in this case, one would tend to rule out inhalants and foods as causative factors and would search again for a focus of infection, such as teeth, sinuses, etc. Trichiniasis might be considered. The history would suggest that there is now a chronic lymphatic obstruction, and if a cause cannot be found the patient might be seen by a plastic surgeon.

Salmonella Typhi O Agglutinin Reaction

Q.—*Is it possible for a subject who had T.A.B. injections seven years ago, and none since, to give a serum agglutination of Salmonella typhi in high titre for "O" and less high for "H," unless he is actually infected now with Salm. typhi? When the test was repeated recently the reaction was found to be less strongly positive, but still above 1 in 100. I understand that an anamnestic Widal reaction shows an increase in H antigen but not in O where some other infection is concerned.*

A.—A positive reaction with *Salmonella typhi* O to a titre of more than 1 in 100 is strongly suggestive of an active enteric infection unless the patient has been inoculated with T.A.B. vaccine within the previous six months. The fact that in this case the O titre was higher than the H would not invalidate this general statement, although the inverse findings are more usual. It is true that the O agglutinins are not usually affected, as H agglutinins are, by non-specific stimuli (anamnestic reaction, such as a non-enteric infection), but if in this case there is no more definite laboratory evidence of infection, such as the isolation of *Salm. typhi* from blood or stools, a positive O agglutinin reaction cannot in itself be taken as proof of infection.

Post-encephalitic Parkinsonism

Q.—*As a child a man aged 40 had sleeping sickness, from which he recovered. He now complains of (a) upward rolling of the eyeballs with loss of vision, which returns after sleep; (b) a condition similar to paralysis agitans; and (c) a general slowing-up effect. What is the likely diagnosis, and what should be the treatment?*

A.—This patient is clearly suffering from post-encephalitic Parkinsonism and the attacks are oculogyral spasms, the latter being a manifestation of encephalitis lethargica, which was much commoner 20 years ago than it is now. The treatment is the usual treatment of Parkinsonism. In the past this has consisted in the administration of drugs of the belladonna group; of these, tincture of stramonium is the most effective. A suitable initial dose would be 10 minims (0.6 ml.) in water three times a day, and this could be gradually increased up to 30 minims (1.8 ml.) three times a day if the patient tolerates it well. Recently new substances have become available. The most effective of these seems to be "artane" (3-[1-piperidyl] 1-phenyl-1-*cyclo*hexyl-1-propanol hydrochloride), which is not yet procurable in this country but is being used in the United States. Next in value is "parpanit" (the diethylaminoethyl ester of phenyl*cyclo*pentane-carboxylic acid), the initial dose of which is 0.00625 g. If the patient tolerates it well, this can soon be doubled and then the dose more gradually increased up to the limit of tolerance. "Benadryl" is also worth a trial. Mental retardation and loss of energy often respond to amphetamine in 5-mg. doses.

Pruritus of Scrotum

Q.—*How should one treat pruritus of the scrotum, occurring mainly at night, in a man of 77 who has suffered from coronary disease for 12 years and still has occasional anginal attacks? There is no rash or sign of irritation. The itching is relieved by cocaine ointment, but each application has brought on an attack of dyspnoea and violent palpitation.*

A.—In pruritus of the scrotum in a man of this age it is important first to be certain that there is no irritation from a dribble of urine or from something in the urine, perhaps sugar occasionally or some other irritant. If any such factor is present and cannot be corrected, then some help may be obtained from the use of a waterproof barrier cream on the scrotum. The question of prostatic irritation may occasionally have some bearing in these cases, but in the absence of an organic or local cause the affection is not uncommonly neurogenic. Cocaine and similar analgesic ointments are not usually desirable and often give rise to trouble by causing irritation or sensitization. Crude tar in a paste or superficial *x*-ray therapy in fractional dosage, combined with phenobarbitone or "sodium amytal" at night, should be helpful.

NOTES AND COMMENTS

Carbachol for Migraine.—Mr. S. G. STEVENSON (joint assistant managing director of Messrs. Savory and Moore Ltd.) writes: In his letter concerning carbachol for migraine (November 19, p. 1177), Dr. J. H. Mellotte states that the German preparation "doryl" and the English one "moryl" are inferior to carbachol. I must point out that both "doryl" and "moryl" are proprietary names for carbachol B.P., and that there is no difference, chemically or pharmacologically, between them and the official preparation. Further, as is frequently the case, carbamylcholine chloride was available to the medical profession under these proprietary names before it was included in the B.P. as carbachol. Although "doryl" is no longer available, "moryl" is still the Savory and Moore branded name for carbachol B.P.

Correction.—Dr. EDGAR RENTOUL writes from the Forensic Medicine Department of Glasgow University: I regret that in the latter part of my article, "Rh Genotype Tests in a Trial under the Criminal Law Amendment Act, 1885," published in the medico-legal section of the *Journal* of December 3 (p. 1300), I was in error, when discussing the theoretical possibility of finding the true father, in stating that the true father must belong either to genotypes Cde/cde or Cde/Cde. While the true father may belong to one of these genotypes, this is not necessarily so. The real position is that the father must carry on one of his chromosomes Cde. There are several genotypes which satisfy this proviso in addition to those which I mentioned. The commonest of these is CDe/Cde; this occurs in 0.8016% of the population. The others are much less common. While, therefore, it might be more difficult to find the true father than I originally suggested, we still have in this case the theoretical possibility of being able to demonstrate paternity by blood

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY DECEMBER 10 1949

THE SECRETARY REPORTS

MEDICAL SUPERINTENDENTS

In this column on November 12 attention was drawn to the regrettable state of affairs which has arisen from the terms and conditions of service of future medical superintendents. The first anomaly is that it is possible under the Ministry's proposals for a specialist medical superintendent to receive less remuneration than a specialist deputy medical superintendent or a specialist medical officer who is neither a superintendent nor a deputy on the staff of the same hospital. The second grievance arises where the amount of administrative time absorbed by the duties is more than trivial as compared with the time devoted by the medical superintendent to clinical work. In my previous note a comment was made that at the worst a whole-time medical superintendent of a large hospital would be regarded for purposes of pay, and so of status, as exactly the same as the lay secretary of a hospital management committee. It was stated that this would mean remuneration somewhere between £640 and £1,700 a year inclusive, the actual remuneration being determined on a points system. But this rate of remuneration applies where the hospital is the only one administered by the hospital management committee. The position is even worse in cases where the hospital is one of a group under the same management committee.

The terms of service prescribe that medical superintendents and deputies will be paid, for that fraction of their time devoted to administrative work, the same fraction of "the appropriate rate for hospital administrative staff." The appropriate rate for hospital administrative staff (to quote the Ministry's own words from the explanatory memorandum which accompanied the terms of service) will be, "where the hospital is one of a group of two or more administered by the hospital management committee, the rate appropriate to an assistant secretary in charge of the hospital." The scale of salaries for assistant secretaries is set out in the Ministry's circular H.M.C. (48) 2 as follows:

Beds	Salary
Up to 399	£450 × £15–£495
400–499	£480 × £15–£525
500–599	£520 × £15–£570
600–699	£595 × £20–£660
700–799	£635 × £25–£710
800 and over	£710 × £25–£910

There is a weighting factor varying from £20 to £50 a year for officers employed in the London postal area. These salaries are inclusive of board, lodging, and accommodation, the value of these emoluments being deducted from the salary shown above. A future medical superintendent devoting half his time to administrative work of a hospital of, say, 450 beds in the circumstances described will receive for that work a starting salary of £240 a year, rising by three annual increments of £7 10s. to £262 10s. a year, and for his clinical work remuneration at the appropriate clinical rate. This is an intolerable state of affairs.

Public Health Medical Officers Employed by Regional Boards

From correspondence received here recently it is apparent that there is at the moment no uniformity in the arrangements for the remuneration of medical officers employed by local authorities who also undertake duties for regional hospital boards on a part-time basis.

This problem concerns medical officers of health and some members of their staffs who before the N.H.S. appointed day were whole-time officers of local authorities and whose duties included commitments as medical superintendents or medical officers of infectious-disease hospitals or similar institutions. Now that these institutions have been transferred to regional hospital boards, it appears that some medical officers who previously held whole-time local authority appointments are having those appointments converted into part-time appointments and are being asked to sign a separate contract in respect of a part-time appointment with a regional hospital board. In some cases a reduction in total remuneration may result, and, in general, repercussions may arise on such matters as security of tenure and superannuation. These problems are engaging the close attention of the Public Health Committee of the Association and are under discussion with representatives of the Ministry of Health.

For the time being local authority medical officers who are asked to accept such a contract in substitution for what was previously a whole-time contract are advised to defer action until the Association has completed its discussions with the Ministry.

Advertisements for Senior Hospital Officers

It will be recalled that the Joint Committee has been discussing with the Ministry the definition of the limited field in which senior hospital officers will be appointed in the future. Some progress has been made in devising a form of words, and the Ministry's final agreement is awaited. In the meantime, we have been endeavouring, whenever an advertisement for a senior hospital officer is submitted, to decide whether or not the successful candidate will be expected to undertake duties which should be undertaken by practitioners of consultant status. We do this because we cannot accept advertisements which invite practitioners to undertake full consultant work but which offer only a grading of senior hospital officer.

As a rule, we find that senior administrative medical officers are helpful in their replies, but some of them are not. The latest to be received is a model of brevity. In reply to the written inquiry, the senior administrative medical officer replies in the following terms:

"Thank you for your letter of November 18 regarding the advertisements we asked you to insert. I regret to say that it is not possible to differentiate between the duties of a senior hospital medical officer and a consultant, and hence to give the guarantee for which you ask."

Incidentally, the guarantee, or assurance, for which we asked was that "these posts do not involve duties which should be undertaken by a practitioner of consultant status."

If the senior administrative medical officer is right in stating that it is impossible to differentiate between the duties of a senior hospital medical officer and a consultant, the sooner the grade of S.H.M.O. is abolished the better, for it means that of the practitioners engaged on certain duties some are paid at one rate and some at another. It makes one wonder whether the only course which can reasonably be adopted is to reject all advertisements for senior hospital medical officers pending an agreed formula. If, on the other hand, it *is* possible to make the differentiation—and many have found it possible—it may be permissible to say that the reply quoted above is unhelpful, is intended to be unhelpful, and so does little to improve the relations between those responsible for organizing the hospital service and those who provide it.

HOSPITAL MEDICAL STAFF

TRANSFERRED OFFICERS

Section 68 (1) (*a*) of the N.H.S. Act authorized the making of regulations for the transfer to regional boards or boards of governors of officers employed immediately before the appointed day *solely or mainly* at or for the purposes of any hospital transferred to the Minister, subject to such exceptions and conditions as might be prescribed in the case of honorary officers. The regulations which were subsequently made under this Section did not contain any qualification as to honorary officers, and it therefore follows that any practitioner who at July 5, 1948, was occupied in his hospital work for the whole or most of his time might claim to be a transferred officer, irrespective of whether or not he was previously on a salaried basis.

So far as the terms of service for hospital medical staff are concerned, the safeguards provided in them for transferred officers are chiefly of interest to those holding appointments which carried a remuneration before the appointed day, as they are designed to secure that the conditions of these officers are not worsened by the new terms.

Thus, transferred officers may retain their previous salary scale and conditions of service, including emoluments, on a personal basis for so long as they remain in the same appointment, but must accept the new travelling and subsistence arrangements. Where a transferred officer exercises this option he will be required to conform to the terms of service on taking up a new appointment or on promotion, except in the case of a new appointment of equal or greater responsibility (measured by remuneration) than the post held at the appointed day, when he may again choose to continue on his old conditions.

In this connexion it is important to note that the conferment of a special distinction award will be regarded as a new appointment, for otherwise a transferred officer who had elected to retain his old terms would not have been able to receive a distinction award.

If a transferred officer decides to accept the new terms of service, his salary, including emoluments, before the appointed day being higher than that which he would receive on the new scale, he will enter the appropriate salary scale at his existing salary (including the monetary value of his old emoluments) and remain at that point until the new scale overtakes it. Charges for residence or other services provided will be deducted.

Superannuation

In the matter of superannuation, the question whether a practitioner is a transferred officer is of significance not only to officers in salaried posts on July 5, 1948, but to those transferred officers previously holding honorary appointments, and particularly to those over the age of 55 on July 5, 1948. The minimum qualifying period for a pension in the N.H.S. scheme is 10 years, but the Superannuation Regulations provide that transferred officers may reckon their previous service (after the age of 18), under any authority whose functions have been transferred, as qualifying service for the purpose of determining whether any benefit is due under the superannuation scheme. This might enable a practitioner who was over the age of 55 on entering the N.H.S. scheme, and who had no previous *superannuable* service, to qualify for a pension at 65 by counting—as a transferred officer—his previous hospital service, although the amount of the pension will be based upon his contributory service.

HEALTH CENTRES

WEST BROMWICH MEMORANDUM

The West Bromwich Local Medical Committee has recently prepared a memorandum on health centres and submitted it to the local health authority and the executive council. In this industrial town with a population of 86,000 about 99% of the population are on the lists of the National Health Service doctors. Of paramount importance, the committee considers, is the need for the average housewife and the mother of young children to have ready accessibility to her family doctor. The committee emphasizes the necessity for general-practitioner beds in hospitals to reduce the professional isolation of many general practitioners.

A disadvantage of health centres is that they may be detrimental to the patients' free choice of doctor. The memorandum points out that a patient's likes or dislikes are related to groups rather than to individuals—to the hospital rather than the individual specialist, and to the firm of general practitioners as a unit rather than to one member of it. "Grouping the doctors of a town who now practise as a dozen and a half firms from an even greater number of surgeries into four or five groups would seriously restrict the choice the patients would feel to be available, and would probably lead individual patients to feel that they had no choice."

RESEARCH IN HOSPITALS

PRIOR APPROVAL OF MINISTER

The Minister of Health has asked hospital boards and committees not to promote new research work needing additional expenditure from their original budget without his prior approval, so that he may consult the Medical Research Council and ensure co-ordination.

As to research financed from "free moneys," the Minister will not interfere with the discretion of boards and committees, but he asks them to indicate broadly the research projects on which this money is being spent and the amount of the expense.

WINCHESTER MEMORANDUM

The Winchester Division of the B.M.A. is seeking support, by means of a circular, for the requisitioning of a Special Representative Meeting to discuss the reorganization of the Association. The Division's two main contentions are: (1) That approximately 70% of members of Council should be directly elected, and (2) that the relationship of autonomous committees to Council must be clearly defined and their activities co-ordinated.

The requisition is asked for in accordance with By-law 46 (1) of the Memorandum and Articles of the Association, which states that a special representative meeting "shall be convened at any time by the chairman of the Representative Body on the requisition of the Council or on the requisition of not less than 20 constituencies."

A report of the Organization Committee on the constitution of the Council was discussed at the meeting of the Council held on November 16 (*Supplement*, November 26, p. 228).

DENTISTS UNITE

The three dental organizations have decided to amalgamate. They are the British Dental Association, the Incorporated Dental Society, and the Public Dental Service Association.

MINISTRY OF PENSIONS

MILEAGE ALLOWANCE FOR PART-TIME M.O.s

As a result of representations made by the Association the Ministry of Pensions has agreed that mileage allowances at the rate of 1s. a mile (or part of a mile) each way outside the radius of two miles, subject to a maximum allowance of 20s. for each return journey, will be paid to part-time medical officers employed on administrative duties. This is in addition to payments made for treatment and those already payable for attendance at medical boards. These allowances are payable with effect from October 1, 1949.

N.H.S. SUPERANNUATION SCHEME

OPTIONS FOR LIFE ASSURANCE POLICIES

When the National Health Service first came into operation, general practitioners who held life assurance policies and were on the lists of executive councils on the appointed day were, subject to certain conditions, given the choice of coming into the superannuation scheme or of "contracting out" and receiving the Government's 8% contribution towards the maintenance of their policies. The option had to be exercised on or before October 4, 1948.

This option was recently extended with effect from August 1, 1949, to practitioners who joined the Service on the appointed day for the performance of part-time specialist services and who at that time were also committed to paying substantial premiums on life assurance policies. The option was available until November 1, 1949, and any contributions paid into the superannuation scheme in respect of the period July 5, 1948, to August 1, 1949, by a part-time specialist contracting out of the scheme will now be refunded.

In making this new option available the Ministry laid it down that a part-time specialist who was also a general practitioner and had exercised the original option would now be automatically excluded from the superannuation scheme in his employment as a part-time specialist.

Following discussions with the Ministry it has now been agreed that a practitioner who has exercised either option will normally be regarded as outside the superannuation scheme for all future N.H.S. work. If, however, the practitioner so informs the appropriate employing authority by March 31, 1950, or within three months of taking up another appointment, he will not be excluded from the superannuation scheme for the work in respect of which he wishes to be in the scheme.

Any practitioner engaged in hospital work who is eligible for inclusion in the superannuation scheme, and who has not exercised either option, will automatically be subject to the ordinary provisions of the scheme.

Questions Answered

Fees for X-ray Examinations

Q.—*(1) Is a whole-time consultant radiologist entitled to charge and retain two-thirds of the fee paid by a private patient examined in a hospital x-ray department? (2) Is a whole-time consultant radiologist entitled to charge and retain two-thirds of the fee of persons examined under Category II in a hospital x-ray department?*

A.—(1) No. A whole-time officer is not entitled to undertake private practice. (2) Yes. The items in Category II are services which the Minister is not committed to provide under the Act, and it is laid down that full- and part-time officers are permitted to retain fees in this category, subject to the proviso that, where hospital, laboratory, and radiological facilities are used, one-third of the fee is retained by or remitted to the hospital.

Elderly Practitioner and Superannuation

Q.—*An elderly practitioner nearing the retiring age of 65 wants to employ an assistant (a) simply as an assistant, (b) with a view to partnership and ultimate succession, or (c) with a view to succession. In each case how will such employment of an assistant affect the practitioner's pension under the superannuation scheme, if the gross income of the practice is £2,000 per annum and the gross income of the assistant or partner £1,000?*

A.—A practitioner who enters the National Health Service near the retiring age of 65, and who intends to retire at that age, will not be entitled to a pension under the scheme. He will be required to contribute 6% of his net remuneration and 8% (i.e., the employer's contribution) of the assistant's salary. He will, on retirement, receive a return of any contributions he has himself paid together with compound interest thereon. If the assistant becomes a partner, he will be responsible for his own superannuation contributions.

Doctor's Wife and Superannuation

Q.—*My wife is qualified and younger than I am. At present domestic duties claim most of her time, but she assists me in emergencies and during rush periods. In the event of my death she would be forced to return to active practice and would presumably take over part of my present practice. Is there any means by which she can start contributing towards superannuation now? Apart from the question of death she will probably take part in clinical work when the children are older.*

A.—A doctor's wife cannot contribute towards the superannuation scheme in the circumstances stated unless she is officially recognized as an assistant or partner.

Choice of Optician

Q.—*Is a medical practitioner in the National Health Service permitted to recommend a particular optician in the Service?*

A.—Under the regulations a patient is entitled, on the recommendation of his general practitioner, to have his eyes tested by an approved ophthalmic medical practitioner or by an approved ophthalmic optician. Whatever advice the doctor may give, the choice lies with the patient.

Heard at Headquarters

Swollen Agenda

Business at Headquarters has accumulated vastly during the last year or two. The other day the General Medical Services Committee's agenda covered 90 items, and one item alone spawned 20 sub-items, almost every one of which called for a discussion. In addition there were reports from five sub-committees. The agenda of the Council the following week covered 94 closely printed or typed foolscap pages, embodying about 40 committee reports. Both chairmen of the two big "autonomous" committees—the Central Consultants and Specialists and the General Medical Services—on their re-election said that they had hoped this second year of their committees' existence would be easier than the first; actually it looks like being more difficult, both in the number and in the complexity of the subjects presented. The remedy is not easy to see. Meticulous care is given to every item, even to such items as have only a local importance or relate to one individual case. At all costs—and the costs are heavy—the democratic principle has to be preserved in reaching any decision. One of the reasons why dictatorship may have commended itself to some communities is that it is, by comparison, so cheap.

Multum in Parvo

The new *Annual Handbook* of the Association for 1949–50 is out, rather bulkier than before, but not increased in length or width, so that it sits easily in the secretarial or other pocket as usual. Few handbooks impart so much information in so small a space. In addition to the usual information about the Association itself, the names and addresses of secretaries of local medical committees, of clerks of executive councils, and of senior administrative officers of regional hospitals boards are all to be found within these orange covers, and a great many other names and addresses as well. The Medical Practices Advisory Bureau and the British Medical Guild are new activities to be recorded. Another new section gives the particulars of the regional offices which the B.M.A. Council has set up in various parts of the country—eight of them in England—with the names of the officers in charge and the local units they serve.

THE REMUNERATION ISSUE

G.M.S. COMMITTEE'S DECISIONS

A special meeting of the General Medical Services Committee was held, under the chairmanship of Dr. S. Wand, on December 1 to consider the letter from the Ministry of Health, dated November 14, intimating that any claim for larger total remuneration for practitioners in the National Health Service could not be entertained.

Before proceeding to consider the next step to be taken, the committee devoted some time to an examination of the computations set out in the Ministry's letter. The chairman estimated that on the basis of the figures given by the Ministry practitioners were receiving at least £7 million less than the sum to which they claimed to be entitled according to the proper constitution of the Central Pool.

Dr. Frank Gray said that, taking as a basis the Spens Report, the matter could be stated quite simply. The agreed figure of what the total income of general practitioners ought to have been before the war was £31.2 million. The claim for 70% betterment would give another £21.8 million, bringing the total to £53 million. This figure, however, was based on 17,900 principals. Taking the Ministry's figure of 18,936 as the present number of principals in the Service, an increase of 5.8% on 17,900, the amount would be brought up to £56 million. The Ministry calculated the money available for 1949–50 at £48.8 million.

Dr. Goodman pointed out that certain items which the Ministry had included in its estimate of the total available for the financial year were for matters which practitioners in 1939 would never have thought of financing out of their own incomes, as, for example, the Inducement Fund (some £400,000). The exchequer superannuation contribution (£2.4 million) should not be considered as implementing Spens. There were a number of items of extra money in this estimate which should not be used to boost up the Central Pool.

Dr. Rose said that the Ministry spoke constantly of "increase" in remuneration, whereas what the profession was asking for was a first settlement.

After further discussion the chairman mentioned possible ways of dealing with the situation: (1) withdrawal from the Service; (2) resort to arbitration; (3) further conversations with the Ministry and challenging of figures; (4) standing by claim but suspending further action until the economic position of the country had improved; (5) no action. He suggested that the line which the committee might desire to take in the first instance might be to approach the Ministry again with a critical examination of its figures, endeavouring to get agreement on the amount of the pool and at the same time seeking an assurance on the implementation of Spens. It followed implicitly from the Spens Report that the Central Pool should be continuously adjusted in relation to the number of doctors and the maximum on the list.

Dr. Dain said that it was essential to keep to the criterion of the number of doctors employed and not the population. They must insist on including in the estimates all doctors in practice, not only those in the Service, for the original calculation included all doctors. The proper assessment of the number of doctors at the present time was important, though when once Spens had been implemented they would be finished with Spens—that is to say, remuneration would not indefinitely be attached to the number of doctors but to the work done.

The following resolutions were adopted unanimously for transmission to the Ministry:

(1) That, in the view of the General Medical Services Committee, the reply of the Ministry (dated November 14) to the request of the Conference of Local Medical Committees for a recalculation of the Central Pool in the light of the facts now available is entirely unsatisfactory and that an interview be sought to demonstrate its inaccuracies, to calculate the sum by which the Central Pool is short, and to reiterate the demand for an adjustment of the Central Pool to meet this deficiency.

(2) That before the January meeting of the General Medical Services Committee an assurance be sought of the Ministry of Health that the Central Pool will be continuously adjusted so as to maintain in the future—whatever the changes necessitated by the heavy burden of work falling on general practitioners and whatever the increase in the number of doctors—the levels of remuneration recommended in the Spens Report and which were accepted by the Government.

In making public these resolutions the committee desired to emphasize that this was not a claim for more money over and above a sum previously agreed, but a demand for a first settlement, and a guarantee that the principles of the Spens Report would be applied to the remuneration of doctors in the Service.

The following were appointed to go to the Ministry with the resolutions: The Chairman (Dr. Wand), the Chairman of Council (Dr. Gregg), the Chairman of the Conference (Dr. Jope), Dr. H. G. Dain, Dr. Frank Gray, and Dr. W. M. Knox.

Medical Certification

In view of the forthcoming publication of the report of the Interdepartmental Committee on Certification under the chairmanship of Mr. Archibald Safford, K.C., the committee considered a letter from the Ministry enclosing a list of some fifty kinds of certificate required by the patient under or for the purposes of various enactments. The Ministry had indicated which certificates should and which should not, in its opinion, be included in the prescribed list of certificates which a doctor is required to issue free of charge to his patients or their personal representatives. The view of the Ministry was generally that certificates relating in any way to the social services, certificates necessitated by rationing and similar controls, and certificates which enabled a person to get other statutory benefits or exemptions fell into the category of certificates which the doctor should be expected to issue without charge, and that certificates which did not fall into these categories, such as those which apparently related solely to fitness for a particular type of employment, and certificates which are as a general rule given by doctors other than the patient's own general practitioner, came into the other category.

The General Medical Services Committee made a painstaking revision of the list, and its observations are to be sent to the Ministry.

Fees for Vaccination and Immunization

A communication from the Ministry was received stating that the Minister had been informed by the County Councils Association, the Association of Municipal Corporations, and the London County Council that they were prepared to agree that a fee of 5s. should be paid to a practitioner taking part in arrangements under Sect. 26 of the Act on receipt of a record in the standard form of the vaccination or immunization of a person on the practitioner's list. It was added that with regard to vaccination the fee would apply either where the first injection resulted in successful vaccination or where the record card showed particulars of a second attempt; and that a third attempt would carry with it an additional fee of 5s. With regard to immunization the fee would apply in respect of the complete process, normally involving two injections. Administration of a boosting dose of prophylactic at a later age would count as a fresh immunization.

The committee accepted the arrangement without prejudice to the question of simplification of the standard form.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Unreasonable Demands by Regional Boards

SIR,—Referees nominated by applicants for hospital appointments are being called upon at so late a date that it is always a matter of chance whether their replies will be received in time. Regional hospital boards fill in typescript forms with a date at the bottom that never allows a greater margin of time than seven days before the reply must be received back, which, allowing for postal delays, gives the referee not more than four days and sometimes less.

Many of us have commitments that may keep us away from our desks for longer than that. And, even when we get back, do the regional boards think that we have nothing else to do, and that everything can be dropped in order to cope with their precipitancy?

Perhaps the whole thing is such a formality that they do not expect a reply. Even that would give some satisfaction, because then we would know that if it had been quite impossible for us to write in time our silence had not been used as evidence against the candidate. But I know of at least one election where my failure to reply was given a most serious interpretation—and yet it was due solely to the thoughtlessness and discourtesy of the board itself.—I am, etc.,

London, W.1. REGINALD WATSON-JONES

Remuneration of General Practitioners

SIR,—We are all being told to work harder and not to ask for more money for so doing. The advice is unpalatable, especially to those who think they were ill-paid last year. Perhaps we are inclined to think the exhortation does not apply to us. Most men will, however, agree that in the interest of the country the advice is sound. The T.U.C. have accepted this view and acted upon it so far as is within their power.

In discussions with the Minister on questions of remuneration would it not be possible to register a protest, stake a claim, but agree not to press it until such time as the financial state of the country is more satisfactory?

I make the suggestion with some diffidence, as I am not in general practice, but with the conviction that the medical profession should not be the last to accept the realities of our present state.—I am, etc.,

Selling, Kent. C. MAX PAGE.

Tax on Prescriptions

SIR,—In the *Journal* of October 29 (p. 971) an annotation enthusiastically welcomes the proposed charge for prescriptions, though in the *Supplement* "The Secretary Reports" (p. 189) comments in a more non-committal way. This schism even in one issue of the *B.M.J.* probably reflects the divided feelings on this matter among doctors.

Mr. Attlee stated that the purpose of this charge was "to reduce excessive . . . resort to doctors." Clearly those who will be thus deterred are those who have to count every shilling—an increasing number of our population as the effects of devaluation and other aspects of the economic crisis develop.

Time was when we criticized patients for not coming to the doctor in the early stages of disease. Surely one of our functions is to see apparent trivialities where anxiety can be allayed and/or prompt measures taken to minimize damage. There cannot be large numbers of those who would be deterred by the 1s. payment who would have spare time to hang about a waiting-room for a matter which they themselves consider trivial.

One can fully understand the worry of a doctor with a busy surgery and much domiciliary and other work to be done, and it is not surprising such an overworked doctor should demur at consultation for apparent trivialities. But can we welcome relief from overwork at the expense of the poorest section of the community—those most likely to need our advice on account of their unhealthy environment? It has even been suggested that the doctor should collect and keep the fee in lieu of increased capitation. I would beg of anyone harbouring such an idea that he refer to the *Supplement* of June 4 and read a letter (p. 310) from Dr. Ian B.-K. MacGregor, who with suitable sarcasm has depicted the probable result.

There are other ways of relieving the burden of overwork on certain doctors. I would recommend the following:

(1) Reduce the maximum number of patients allowed on a doctor's list. I would suggest a reduction to 3,000 as an immediate target, to be followed by a further gradual reduction to 2,000 as more G.P.s are trained.

(2) Increase the efficiency of our work by the provision of health centres on a large scale. In these, with adequate ancillary staff, our treatment of patients, including all trivialities, could undoubtedly be greatly speeded up and made more efficient. Moreover, the whole scope of general practice could be so extended as to take quite a burden off hospital outpatients. Is this too expensive for a country which spends enough on a grossly swollen military machine to build 5,000 first-class health centres a year? If so, let us halve the expenditure on destruction and devote the money saved to construction.—I am, etc.,

Brighton. R. S. SAXTON.

SIR,—The profession seems to have forgotten two very important and elementary factors in giving official (albeit lukewarm) approval to the Government's proposed shilling-per-prescription tax. First, this will mean that payment is demanded before treatment is given, and if payment is not made treatment will not be given; and, secondly, it is inhuman to tax illness.—I am, etc.,

Sixpenny Handley, Wilts. PAUL HARRIS.

Two Alternatives

SIR,—With regard to the letter (*Supplement*, November 19, p. 218) received from the Ministry of Health, delivered with the obvious intention that the last word has been said on this vexed question of remuneration, I feel that now we know exactly where we stand in the matter we can do something. We can do one of two things.

(1) We can refuse to continue to operate the Service under the terms imposed on us. We can do so provided we have the solid backing of the majority of the profession, provided that now in this engagement we close our ranks and take the initiative. This solidity of opinion and of action is something which is necessary, but can we count on it? I think our weakness will rest in the ranks of those who have maximum lists or who have large lists with few if any family commitments—in short, people who are sufficiently well off under the scheme to be indifferent to the fate of their less fortunate colleagues, who are not prepared to jeopardize their relatively large incomes by supporting any resistance movement as a whole. This is our weak point and we must recognize it. Unless a majority of doctors are prepared to withdraw from the Service, nothing can be done to obtain better terms. This brings us to the second thing which we can do:

(2) Accepting defeat by the Minister, we can lick our wounds and make the best of a bad job. To make the best of this bad job we must have a redistribution of the funds provided. If we are to have no more, let us make the best use of what we have. We cannot with justice to all continue to provide a uniform capitation fee of approximately 18s. We shall have to do what we planned to do with the larger sum which we had hoped for and lessen the disparity of incomes between those with maximum lists and those who have small lists. We shall have to take the fund and arrange it so that we get, say, 25s. for the first 1,000 and 12s. for all the rest. This will result in a reduction of income in the case of those with the large lists, but it will very materially assist those who are deprived of the opportunity to earn a decent living, generally through no fault of their own. This is what we must do if we accept this rebuff from our Minister. To avoid unnecessary argument regarding the amounts to be paid, I must mention that the figures given are merely serving to illustrate the *method* of payment.

In short, the position is clear. We fight for our rights as a solid body of medical men at last asserting themselves, or we accept defeat and put our financial house in order.—I am, etc.,

Anstruther, Fife. M. D. S. ARMOUR.

Private Practice for M.Os.H.

SIR,—It is impossible to read without dismay the reply given by Dr. Kershaw (*Supplement*, November 19, p. 221) to my letter regarding the stagnation of negotiations on salaries for M.Os.H. It was surely obvious from the outset of my letter that the salary of £750 per annum was in no way related to the M.O.H. but to the overwhelming proportion of medical officers who form the public health service and having, of course, a status other than that of M.O.H. This terminological inexactitude, to use a Churchillian expression, can be assumed to be patently obvious to those well-informed persons who form the bulk of the readers of the *B.M.J.*, and I very much doubt, therefore, if it engendered any irrepressible desire on their part to ridicule this *lapsus linguae*.

Dr. Kershaw contends that I did not even trouble to get my facts right, and to support his contention he differentiates regarding £40 per annum. It is mathematically perplexing, however, to find that he finally agrees that even £850 per annum is deplorably low. However, I submit that my letter could not have been so "wide of the mark" as Dr. Kershaw tries to make out, as seven authorities—to wit, Rochdale, East Ham, Derby, Caernarvonshire, Southampton, Leeds, and Middlesex—advertise vacancies in the *Journal* of November 19 (in common with many previous advertisements of other authorities) with salaries of £735. Whether on the evidence Dr. Kershaw is any more within the mark with his value of £710 per annum against my £750 can be left to the discretion of the reader.

The incongruity of the conclusion drawn by Dr. Kershaw to the effect that, if I were right, the majority of assistant medical officers of health, etc., must needs have resigned in disgust within a year or so stands therefore on its merits.

Dr. Kershaw's attempt at mind-reading through the medium of my letter is indeed a "rendering," for his idea that I "admirably calculated to produce precisely the wrong impression" and advised an austerity-minded Government "to keep their salaries low, but make the lazy fellows stir themselves" is as ridiculous as the imputation that private practice in this case should be regarded as "earning money 'on the side.'"

I should like to make it quite clear that, as a member of that service, nothing was further from my mind than an attempt to belittle its great achievements. I am at a loss, however, to offer any lucid explanation of the motives of persons who, regarding themselves as authorities in public health and preventive medicine, find it necessary to indulge in superlatives about our own apparent achievements to the derogation of institutions of other nations.

It is remarkable how acidly and with what convenient facility Dr. Kershaw extracts a phrase from the context of my letter and brings about a transmutation of words to prove that I would have in my letter intentionally graded public health as a "second class" science to other branches of medicine, consequently concluding in questioning my suitability to remain within the scope of public health.

My contention that our salaries are frozen for good has in no way been affected by the patronizing and crusading reply given to you by Dr. Kershaw.—I am, etc.,

Accrington, Lancs. J. KATZ.

Prescribing of Appliances

SIR,—I enclose some brief notes which I recently submitted to my medical staff committee drawing attention to the unsatisfactory state of affairs in regard to the supplying of surgical appliances under the N.H.S. I feel that they may be of interest to general practitioners and also to those who have to conduct such a clinic.

It is a soul-destroying occupation requiring considerable diplomacy. A large proportion of patients, in my opinion, do not require surgical appliances, and quite a number have no sign of the complaint for which an appliance has been ordered by their doctor. This involves the risk of antagonizing large numbers of local G.P.s by refusing to endorse their prescriptions, or alternatively a policy of irresponsible acquiescence which is highly uneconomical.

I have had no guidance on the criteria by which these cases are to be judged. The vast majority of patients are fat old bodies, sent up with the quite incorrect diagnosis of "severe visceroptosis." These could quite well buy utility corsets such as they have worn for years, and I see no reason why the State should provide them with surgical corsets at considerable expense. There are quite a number of cases of ventral hernia, some of which can indeed be controlled by a belt or corsets specially designed. On the other hand many of them require operative cure, as they are of such a nature that an appliance would not control them.

There are usually two or three patients sent up for wigs. Some of them are young women with alopecia—fair enough. But I have seen middle-aged men, and in one case a woman with a full head of grey hair. These were refused. Senile patients have been sent up with a request for a mechanically propelled chair. They will presumably ask for a new Morris 8 next. People with oddly shaped feet of many years' duration are provided with free shoes made to measure. There must be countless thousands of these waiting to cash in and never buy a pair of shoes again.

It will thus be seen that this "appliances racket" is one which will grow like a snowball to dimensions quite beyond economical fulfilment. I consider that rules and regulations from the Ministry of Health are a necessary protection for those in the unenviable position of having to judge these cases.

The Ministry of Health has, indeed, issued an enormous schedule of appliances, many of which I am sure have never been heard of in a normal course of surgical training, but no advice is given about the indications for prescribing them at the taxpayer's expense.—I am, etc.,

Portsmouth. A. N. H. PEACH.

Domiciliary Midwifery

SIR,—It would appear that the Royal College of Gynaecologists and Obstetricians think so little of the general practitioner that they are making great efforts to preclude him from practising midwifery. To anyone really *au fait* with the problems of domiciliary midwifery it is obvious that, despite a few examples of incompetent G.P. obstetricians, by and large the G.P. who is frequently caring for midwifery cases, both normal and abnormal, is performing a great service to the mothers of this country. It would take up too much valuable space to enlarge on this point.

But, as the midwife still undertakes the care of the bulk of normal cases in this country, does the noble College condemn all mothers who are fortunate enough to be normal cases to be denied all sedatives other than pot. brom. c. chloral, and all other analgesics other than gas with a varying amount of air?

In my opinion the College would do better if it left the G.P. alone and saw fit to press for legislation allowing the midwife to prescribe—with suitable regulations—pethidine, and allow her, too, to use trilene analgesia. There are at least two machines on the market that are foolproof. I have no doubt that normal cases which are in hospital nominally under the care of a specialist in obstetrics have the benefit of these aids when delivered by the hospital midwife.—I am, etc.,

London, S.W.11. IAN SAMUEL.

Buy and Sell Practices

SIR,—Undoubtedly the time has now come when all doctors should stand firm together and should say to Mr. Aneurin Bevan: Dear Mr. Bevan, we have no further use for you, we will no longer work for or with you; we will revert to our ancient, time-honoured, and, for most of us, verminous practices. We will charge our patients for our services as of old, and we will buy and sell our practices as and when we like.—I am, etc.,

Bracknell, Berks. R. H. P. HICK.

"Need" and "Must"

SIR,—I understand that the terms of reference for the Sir Henry Cohen Committee are, briefly, to define those drugs and appliances for use by general practitioners beyond which they need not go. I hope that this committee will remember medical

history and so word their recommendations that the operative word remains "need" and cannot be changed to "must."—I am, etc.,

A. HENRY GREGSON.

Cromer, Norfolk.

Constitution of Council

SIR,—In his letter (*Supplement*, December 3, p. 247) Dr. Ronald Gibson accuses the Organization Committee and the Council of sloth, of ignoring the instructions of the Representative Body, and thwarting the will of the profession. All these strictures are based on erroneous statements.

The Organization Committee is, of course, a Standing Committee of Council and has been in existence for many years. It was not, as stated by Dr. Gibson, appointed at Cambridge in 1948 with certain "terms of service." No resolutions were passed at the A.R.M. at Cambridge requesting any alteration in the methods of election of members to Council.

After this meeting Council decided to review the B.M.A. constitution and machinery. The Organization Committee gave first priority to the methods of election to Council, and took note of the various Winchester Memoranda which were being circulated at that time, and invited representatives from Winchester to meet it. Early this year Council adopted proposals for a radical change in its constitution, and these were brought before the A.R.M. at Harrogate last June. The best part of one morning was occupied in discussing them, with the result that the R.B. passed one positive resolution—i.e., that the number of members directly elected to Council should be increased. The proposals of Council were referred back. The debate was controversial and showed that there was much difference of opinion on details. If a majority of Divisions agree with Winchester it is odd they did not make this apparent at Harrogate. Dr. Gibson says that Council has decided that there should be a certain number of co-opted members; in fact Council referred a suggestion to this effect to the Organization Committee for study and report. Council agreed on November 16 that there should be an increase in the number of directly elected members.

The Winchester Division has asked Divisions to support a demand for a Special Representative Meeting. Council considered a proposal that an S.R.M. should be held and decided against it by 25 votes to 18. The reasons that actuated the majority were not given in the necessarily abbreviated report in the *Supplement* of November 26 (p. 228). They were:

(1) The statement of the Treasurer that the cost of a Special Representative Meeting would be about £1,000.

(2) There will be a four-day meeting of the Representative Body next year instead of the usual three-and-a-half, and this should provide ample time for debate.

(3) It would be a hardship both to Division and to candidates if electoral areas are changed just before an election.—I am, etc.,

J. A. PRIDHAM.

Weymouth, Dorset

Urgent Admissions to Hospital

SIR,—Dr. I. Langdale Gregory's letter (*Supplement*, November 19, p. 222) gives expression to such an undesirable attitude on the part of hospital registrars towards their (frequently more experienced) colleagues in general practice that we feel compelled to intrude upon your columns in order to show that not all registrars think thus.

The percentage of G.P.s who may adopt the tactics mentioned in order to obtain admission of their patients is small, and Dr. Gregory must hold a poor opinion of the integrity of consultants if he thinks that they would be a party to this practice. In our opinion the great majority of G.P.s are honest in the details they submit about their cases.

The tendency to reduce the G.P. to the status of a not very competent first-aider is becoming all too common. He is expected to have a working knowledge of all the specialties; he has to bear with the suggestions and proposals of the patient and his relatives (nowadays often dangerously learned in medical matters by an ill-informed lay press). Think of what an overworked conscientious G.P. must feel when he contemplates a critical visit of a hospital registrar (one who all too frequently nowadays knows less in all branches of medicine other than in his own field than his experienced G.P. colleague), and whose virtual function will be to affirm or deny the G.P.'s assessment of the case. One cannot escape the conclusion that Dr. Gregory tends to classify G.P.s under two classes: (1) those who wilfully misrepresent the true picture, and (2) those who are so incompetent that they are unable to assess the true picture.

May we add that the idea of a lot of registrars milling about in the fog to find genuinely urgent cases warranting immediate admission is worthy of a Marx Brothers film, were it not for the horror of its cost in time and taxpayers' money and the pernicious reflection implied upon the medical skill and moral integrity of our G.P. colleagues?—We are, etc.,

K. G. GREEN.
F. P. O'SULLIVAN

London N 19

Unfortunate Position

SIR,—After the second plebiscite our representatives advised us to join the Service. Neither they nor the Government issued commands. "Principal" (*Supplement*, November 19, p. 223) could have continued offering his services to the patients who preferred his attentions to those of his six local competitors, but being shrewd enough to realize that their passive preference for him might change to active preference for someone else, with very obvious financial results, he joined the Service. The important point is that, knowing the conditions of joining of which "unspecified amounts" and "indeterminate date" were parts, he elected to do so. It was a personal decision, and the lesser of two financial evils. That he was manœuvred into such a position, which only allowed him a Hobson's choice, was unfortunate, but he can't blame the Government for it—much as we'd like to. He must blame his colleagues—roughly 60% of them—who could not trust each other to put principles above money.

Having voluntarily given up his capital (his practice) for an annuity (the "unspecified amount" at "an indeterminate date"), he now not only states that he didn't sell his practice, but wishes and is allowed as much control in its use and distribution as he rightly had before July 5. He should be very grateful to his fellow principals who represent the profession for arranging this. If they had looked after the unestablished doctors' interests as carefully the gratitude would be more general. I mentioned this point in my original letter from which the extracts were taken, and suggested a reason and a remedy for the negligence.

With your permission, Sir, I will leave the side-tracks which lead to basic salaries and relay races for another occasion.—I am, etc.,

D. G. SMITH.

Cambuslang, Lanark.

Size of Capitation Fee

SIR,—It is difficult to understand how anyone with even a smattering of knowledge of the policies of drift, extravagance, and expediency of our present rulers could have imagined that the profession had the slightest chance of securing a large increase in the capitation fee, however righteous our claim, unless the profession itself was prepared to take extreme measures to enforce compliance with its demands. On the other hand no realist who acknowledges that a great many doctors are better off than they ever were, or might have ever hoped to become, can envisage adequate support for extreme measures.

Is it altogether unreasonable to ask that our leaders and representatives should now desist from baying for the moon and turn their attention to the gross injustice implicit in the fact that the present capitation fee can vary by as much as 3s. 1d. as between one area and another? The explanation handed out *ad nauseam* by B.M.A. officials and by the Ministry is that the difference is to be accounted for by certain first charges on local pools. The Ministry is able to add that the method of distribution has been agreed by the profession. It seems that anyone who agreed to anything which would lead to such inequity should be willing to admit that a mistake had been made and that under a national health service there should be a national capitation fee.

I have gone to some trouble to analyse the last statement sent by the Executive Council for Cornwall, and so far as I can make out there is a sum of £25,000 in a full year which is not accounted for even if one deducts all the prior charges and compares with what the position should be to give us the highest existing capitation fee, 17s. 10d. per annum, even on the unlikely supposition that there are *no* prior charges on the local pool of the Shangri-La where that amount is paid.—I am, etc.,

Launceston, Cornwall. DONALD M. O'CONNOR.

SIR,—There seems to have been surprisingly little reaction to your recent publication (*Supplement*, October 15, p. 169) of figures which show that there is as much as 3s. per annum difference in the capitation fee paid to doctors in various parts of the country.

Here in Cornwall we are receiving quarterly emoluments equivalent to an annual payment of 15s. 6d. We are thus 2s. 3d. per head less well paid for our patients than doctors in relatively more fortunate areas—a gross sum of £36,514. We are told that the difference is to be explained by emergencies, anaesthetics, basic salaries, and so on, but according to the most recent statement these account for a net reduction for the quarter of £2,812 or £11,248 for a full year. This seems to leave £25,266 entirely unaccounted for even if one accepts in full the explanation put forth by both the B.M.A. Secretariat and officials of the Ministry.

If £25,266 can disappear into thin air in one area, there is little reason to suppose that the figures in others where the doctors are paid so much less than the 18s. which was originally mooted could stand up to very close scrutiny.

One seems not to need to look as far afield as the groundnuts scheme to find an odd financial muddle.—I am, etc.,

Polyphant, Cornwall. GEORGE MCC. ROBSON.

Fixed Capitation Fee

SIR,—I trust my ignorance of national economics may be excused. My simple mind fails to understand why general practitioners cannot be paid a fixed annual sum, say 18s., for each patient on their lists, instead of an indeterminate amount arrived at by dividing a computed figure representing a hypothetical percentage of the estimated population of the U.K. into an astronomical number of £m., which "global" sum is determined by a devious mathematical process involving so many unknown or conjectural factors that the answer can only be correct to within plus or minus *x*.—I am, etc.,

Stirling. J. E. MORRISON.

More Patients Now

SIR,—It seems to me fallacious to base the remuneration for general medical practitioners on total pre-war earnings.

The Minister of Health has stated in support of the health scheme that a large number of people previously unable to afford to get medical attention now get it and many more now get attention earlier. If these people had got medical attention before the war and got it earlier the total general practitioner remuneration would have been much more, in fact probably doubled or nearly so.

Therefore it is clear by the Minister's own statement that the present general practitioner remuneration is too low, for surely I as a general practitioner am to be paid according to the amount of work I am expected to do. If there were a panacea to prevent all forms of illness and given to all, I would have no work to do and would be paid nothing.—I am, etc.,

Leigh-on-Sea, Essex. A. H. LEVERS.

Registrar Group

SIR,—I for one was full of hope at the formation, within the B.M.A., of a Registrar Group. Having attended the inaugural meeting I am full of foreboding at the prospect and would be dishonest to myself not to express these misgivings.

Most will agree that the problems of the two types of registrar—teaching and non-teaching—are different. The new organization seems to contain very many members from non-teaching and very few from teaching hospitals, while the organizers do not seem such as make the teaching registrars feel that their interests will be adequately served.

The registrars from teaching hospitals must choose from two courses. Either they can follow their fears that their quiet voice will be drowned in the present conclave, and completely boycott the organization; or else they enter it with all the power they possess to re-form it. The first is a counsel of cowardice, the second a tiring tedious task.

The registrars from the non-teaching hospitals have an organization in which they can make their voice heard. Majorities can overthrow minorities, but in so doing sow the seeds of their own inevitable destruction. The caution of the teaching-hospital registrars to this group has been founded mainly on doubt and suspicion. Nothing happened at the inaugural meeting to disperse these feelings, whereas much happened to aggravate them.

The group must make determined efforts to gain the confidence of the teaching-hospital registrars. Only then can it claim to speak with one voice for the whole registrar class.—I am, etc.,

Stanmore, Middlesex. HAROLD E. THOMAS.

Supplementary Ophthalmic Service

SIR,—Dr. Charles Cockburn's letter (*Supplement*, November 19, p. 222) draws attention to the scope of the Supplementary Ophthalmic scheme, but, whilst agreeing with his main contention—namely, that the scheme provides for a "sight-testing" examination only—I feel that there is another side to the problem.

The cases of ocular pathology enumerated by your correspondent form only a small proportion of the total using the scheme, and even these are not always easy of diagnosis. It is difficult for the general practitioner to divide all ophthalmic cases into those which are "pathological" and those which are not. Most patients complain of symptoms—e.g., headaches, defective vision, etc. These may or may not be due to "pathological" causes. The great majority are not, but in many cases only expert examination can tell. The Supplementary Ophthalmic Service provides this.

Dr. Cockburn ignores the fact that the Supplementary Ophthalmic scheme is not mediated solely by "sight-testing opticians." The majority of ophthalmologists in this country participate in the scheme, either at medical eye centres or at their own rooms. Also, there must be many areas where hospital facilities are not so readily available as in large centres like Aberdeen, in which case the presence of a medical eye specialist operating the scheme is an immense boon.

It is rather hard on patients that they should be sent, perhaps quite unnecessarily to hospital to wai possibly for hours, possibly in discomfort, when they can be seen through the Supplementary Ophthalmic scheme in comfort and at a time convenient to them. It is also rather hard on the unfortunate hospital officer, who has usually quite enough to do coping with the work he has. I feel that the Supplementary Ophthalmic scheme performs a very useful function in saving the hospitals much unnecessary work with which they were formerly burdened. Also, it must be instrumental in sending to hospital many cases requiring hospital treatment which might not otherwise have been sent, and at an earlier stage than was formerly the case.

That the scheme has cost as much as it has is simply the expression of an unsatisfied need which far exceeded all expectations. It should not be condemned on the evidence of one example of what would appear to be excessive zeal. There should be machinery for dealing with that sort of problem. To my mind, it is one part of the Health Scheme which has justified its existence, and must have increased enormously the ocular efficiency of large numbers of individuals. And what greater contribution to national efficiency could a national health scheme be expected to devise?

It may be done more cheaply, possibly at the expense of the ophthalmic practitioner, and at great public inconvenience, but I doubt whether it would be done as well. It would probably not result in fewer glasses being prescribed. It is my belief that very few pairs of glasses are prescribed unnecessarily, and

there are many cases in which it is a matter of opinion whether they are necessary or not. The prescribing of glasses is not entirely a matter of correcting refractive errors.—I am, etc.,

R. U. GILLAN.

London, W.1.

POINTS FROM LETTERS

General Practitioners' Pay

Dr. S. SHUBSACHS (Manchester) writes: Dr. W. A. H. Bell (*Supplement*, November 12, p. 211), who is not a National Health Service G.P., is satisfied that the G.P.'s salaries are adequate—because they have other sources of income in many cases as he did before the war. Sir, what was Dr. Bell's income, and how did, and does, it compare with the present average of a G.P.? Dr. Bell tells us that there is still a lot of private practice. Most patients know that they have only to hand in their card to get the same treatment free, and most of them have done so. Private practice is dead. . . . Most of Doctor Bell's part-time jobs are now full-time with no private practice, and the G.P. specialists are in fact dying out. . . . What irks most is the sneer at the end of his letter about more money for less work. That is pure humbug, as even the Minister of Health is aware that the G.P.'s work has increased and claims that the shilling per prescription will help to reduce it. . . .

Dr. ALEC WATTISON (Crail, Fife) writes: . . . If he [Dr. Bell] were practising in this area he would find that there are no other methods of adding effectively to one's income. Extra appointments are non-existent; private patients can be counted on the fingers of *one* hand, and amount to 0.2% of the practice. There is no time to take on other specialist work and do it adequately. The nearest hospital for carrying out investigations is roughly 23 miles away over a ferry. . . . Has he any idea of the difficulties of, and the financial strain involved in, buying a share in a practice, buying a house, keeping a family in adequate comfort, and educating children decently in a country where his eight or nine shillings is equivalent to twenty or twenty-three present-day shillings? Or for that matter, after ten or so years' experience, found himself looking for appointments that were already filled by younger and less experienced people who had not done four or five years' service abroad with the Services? . . .

Association Notices

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1950. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff or senior hospital medical officer of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1950 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

The title of the proposed essay and the motto should have been notified in writing to the Secretary by December 1, 1949, on a form obtainable from the Secretary. Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1950. The prize will be awarded at the Annual Meeting of the Association to be held in 1950. Inquiries relative to the prize should be addressed to the Secretary.

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than December 31, 1949. The prize will be awarded at the Annual General Meeting of the Association to be held in 1950.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Preliminary notice of entry for this competition is required on a form to be obtained from the Secretary.

8. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

9. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

10. Inquiries relative to the prize should be addressed to the Secretary.

PRIZES FOR MEDICAL STUDENTS, 1950

The Council of the British Medical Association is prepared to consider the award in 1950 of prizes to medical students for essays submitted in open competition.

The subject of the essays shall be "Clinical Teaching in Relation to the Practice of Medicine."

The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for a prize.

If any question arises in reference as to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. In determining the number and the value of the prizes to be awarded the Council will take into consideration the number of essays received. Should the Council decide that no essay entered is of sufficient merit, no awards will be made.

Each essay must be typewritten or legibly written in the English language, on one side of the paper only, must be unsigned, and must be accompanied by a form of application

separation of much less active fractions, there was a tendency to discredit the Norwegian workers. Thus they have never received proper recognition for genuine achievements that were not bettered during the next ten years. Moreover, their description of their most active fraction as a bright reddish-yellow substance acquires new significance in the light of present knowledge.

We were accorded the privilege of examining their case reports at the time; although in several instances the responses were inadequate with the very small doses given, there seemed no doubt that the fractions tested were very much more active than anything previously obtained. In addition, we were able to secure independent clinical tests on some of their less highly purified fractions, which proved fully active in single doses of less than 10 mg. It should be added that their methods of fractionation have provided an invaluable foundation for our own work. Karrer and his colleagues (1938) also reported the preparation of fractions fully active in doses of 10 mg., or rather less, by methods that were not described in detail.

It is difficult to assess the work of Jacobson, SubbaRow, and others published between 1935 and 1938 (see SubbaRow *et al.*, 1945). These workers claimed that successful treatment of pernicious anaemia called for the simultaneous administration of several factors. One of these was identified as *l*-tyrosine, but the others were not fully purified. Their theory was supported by a reasonable weight of clinical evidence, but it has not been widely accepted. Ungley has now presented ample evidence showing that the pure crystalline anti-pernicious-anaemia factor alone, in adequate doses, gives a classical response in cases of pernicious anaemia. One is inclined to suggest, therefore, that the supplementing action of Jacobson and SubbaRow's accessory factors may have been due to contamination with small proportions of their primary factor (presumably the anti-pernicious-anaemia factor in crude form); satisfactory responses might well have been obtained with larger doses of the primary factor alone.

No further significant advance was reported until 1945, when Emery and Hurran reported a concentrate fully active in a dose of 5.5 mg. In the following year Emery and Parker (1946) reported further concentration to a preparation active in a single dose of only 1 mg. These fractions were made by application of known techniques—in particular, repeated adsorption on charcoal, elution with phenol or with hot 65% alcohol, and salting-out with ammonium sulphate.

It is something of a tragedy to recall the considerable amount of analytical work that has been performed by some groups of investigators on material now known to have contained as little as 0.01% to 1% of the pure factor. It must be confessed that we fell into the same error ourselves in making preliminary chemical investigations on material containing only about 3% of the factor, under the impression that it must be approaching purity. It seemed appropriate at the time to carry out the various analyses, for there was no reason at all to anticipate the phenomenal potency of the crystalline factor. We now know that the human requirement is only about 0.001 mg. a day. The only substances known to be physiologically active in smaller amounts are such poisons as plutonium and botulinus toxin.

Partition Chromatography

Reviewing the situation in 1946 it seemed to us unlikely that any further advance would be made without the introduction of new techniques. There was also little doubt that the new approach required was some form of chromatography, preferably perhaps the recently introduced partition chromatography. This method employs a tube packed with an inert porous powder capable of soaking up a considerable proportion of water without appearing damp; the material to be separated is applied to this column dissolved in an organic solvent not completely miscible with water, and development is continued with the same solvent. These columns do not differ in appearance from the familiar adsorption chromatograms using alumina, for example, but the mechanism of separation is different: it depends on differences in the partition of the various substances present between water (held in the pores of the solid) and the solvent, instead of upon differences in adsorbability. Such partition chromatograms, using damp silica and butanol, fulfilled our expectations. Liver extracts, sufficiently purified by the methods already outlined, separated readily into three coloured zones. Yellow material travelled quickly down the column; a pink zone travelled very much more slowly; a brown zone remained near the top of the column, with a tendency to overlap somewhat into the pink zone. Nearly colourless material was also present between the pink and yellow zones.

It was an obvious step to use these colours as a guide in cutting up the chromatogram, but we were surprised to find it so effective, for nearly all the clinical activity was concentrated in the pink fraction. The same thing happened in other experiments. Nevertheless we expected that this would turn out to be merely an adventitious association of a red pigment with the active principle, and a faulty interpretation of some later experiments seemed to confirm this view. Already we had reached the stage of purification where a ton or so of liver was needed to provide a workable amount of material, and the lengthy procedures for preliminary concentration as well as inevitable delays in clinical testing made progress very slow.

About this time we received temporary discouragement from the announcements that folic acid was effective in pernicious anaemia, and that it could be made synthetically. It was soon clear, however, that our liver concentrates, though still impure, were weight for weight much more effective than folic acid. We were therefore dealing with a different substance, and its isolation was still of academic interest at least. Then, as the clinical shortcomings of folic acid gradually came to light, interest in the liver factor revived and indeed intensified.

The Active Red Factor

By now we were satisfied that colour and clinical activity were inseparable, but our pink material obstinately refused either to crystallize or to respond further to attempted purification by repeated partition or adsorption chromatography, fractional salting-out, or fractional precipitation by solvent mixtures. After a long period of frustration, further progress came suddenly from the observation that treatment with proteolytic enzymes like trypsin would break down persistent peptide impurities. On repurification by partition chromatography the product from the red band was eight times as intensely coloured as any previous fraction; it was later shown to be correspondingly more active clinically.

After a few more weeks spent in further purifying the minute amounts of red fractions remaining, we had the final satisfaction of watching the pure substance crystallize from aqueous acetone. But during those last weeks we were forestalled by the announcement that the Merck team under Karl Folkers had added one more vitamin to their conquests by isolating the same substance in crystalline form. Following proof of identity by exchange of

specimens (Lester Smith, 1949) we have now adopted the name vitamin B_{12} suggested by the American workers.

It is worth noting that the methods we have used for the isolation of the anti-pernicious-anaemia factor are almost exclusively physical rather than chemical (Fantes, Page, Parker, and Lester Smith, 1949). In other words, we have depended on such physical properties as solubility in salt solutions and solvent mixtures, adsorption on charcoal, alumina, and silica, and partition between water and solvents. The countercurrent principle, upon which both adsorption and partition chromatography depend, enabled us to exploit the small differences in such properties between the factor and associated impurities.

This has been necessary because the factor is singularly devoid of characteristic chemical properties. The only chemical precipitants that have been used with advantage are Reinecke acid and phosphotungstic acid, but these are not at all specific, as both will precipitate many basic compounds. Moreover, neither is essential to the isolation of the pure factor.

Here, then, is another reason why the pure factor could hardly have been isolated in earlier years before some of these physical methods were perfected.

Standardization of Dosage

One considerable advantage that will follow from this work is the ability to express the dosage of liver extracts and other concentrates of anti-pernicious-anaemia factor in accurate and logical terms. The microbiological assay method using crystalline vitamin B_{12} as a standard permits standardization in terms of vitamin B_{12} activity. There will no longer be any excuse for stating dosages as the number of millilitres of a liver extract or the milligrams of crude solids administered, or in "liver equivalents" or the weight of liver from which the dose is prepared. Clearly, all these are misleading on account of variations in the potency of the original liver, variable yields in the course of extraction and purification, and differences in the extent of purification as between one liver extract and another. On the other hand, the growing body of evidence that liver extracts owe their efficacy in macrocytic anaemias solely to their vitamin B_{12} activity, which can be accurately assessed microbiologically, puts this method of standardization on a very firm foundation.

Three Interesting Points

Interest did not slacken, even temporarily, with the isolation of crystalline vitamin B_{12}. For one thing, we were able to provide evidence (Lester Smith, 1948a), since reinforced (Cuthbertson and Lester Smith, 1949), for the existence of a second red factor, also clinically active in pernicious anaemia; indeed, it now appears probable that there are three such factors (Lester Smith and Cuthbertson, 1949). It is not known whether the others are more complex substances incorporating the molecule of vitamin B_{12} (analogous to the various conjugates of folic acid with glutamic acid) or whether they are chemical modifications of vitamin B_{12} (analogous to the various kinds of vitamin D or of penicillin).

The isolation of one of these factors in crystalline form has recently been announced from the Lederle Laboratories (Pierce *et al.*, 1949). It has been named vitamin B_{12b}, the name B_{12a} having already been used for an artificially produced hydrogenation product of vitamin B_{12}.

Secondly, the chemical nature of vitamin B_{12} is gradually being unfolded as supplies of this very scarce material become available. (See Lester Smith, 1948b; Rickes *et al.*, 1948b; Kaczka *et al.*, 1949; Brink *et al.*, 1949: Ellis *et al.*, 1949; and Brink and Folkers, 1949.) The most surprising discovery, announced almost simultaneously by the British and American teams, was the presence of an atom of cobalt in the molecule—the first time this metal has been found in a pure substance of biological origin. This has given rise to a crop of speculations on the function of cobalt in nutrition, and the relation (if any) between vitamin B_{12} and the already known need of ruminants for cobalt. The molecule of vitamin B_{12} contains some readily hydrolysable group essential to its microbiological activity, since it is slowly inactivated by cold acid or alkali. This might be a phosphate ester group, although the phosphorus present is completely split off only on long heating with acid. This treatment also liberates a substance giving a positive ninhydrin reaction, but leaves the greater part of the molecule intact and still retaining the cobalt, though with altered solubilities. This has been disrupted only by fusion with alkali, when pyrrolic substances are released, suggesting some structural relationship with chlorophyll and haem pigments.

A third point of interest is a promising new source of vitamin B_{12}. This arose from an entirely different research on the "animal protein factor" required by chicks and some other animals reared on a vegetable-protein diet. It now appears likely that this factor is identical with vitamin B_{12}, but meanwhile it had been established that the factor is synthesized by some intestinal bacteria. This raised the possibility of production by a fermentation process, and the Merck group, doubtless turning first to fermentations already established, found that the factor is produced by *Streptomyces griseus* and succeeded in isolating crystalline vitamin B_{12} from the metabolism fluid of this organism (Rickes *et al.*, 1948c). Whilst the isolation of the crystalline product remains at present a complex and expensive procedure, the industrial production in this country of a purified vitamin B_{12} concentrate from fermentation liquors is now at an advanced stage. It is expected to become generally available shortly.

VITAMIN B_{12} IN PERNICIOUS ANAEMIA: PARENTERAL ADMINISTRATION

BY

C. C. UNGLEY, M.D., F.R.C.P.

Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne

With Statistics by H. CAMPBELL, B.A., F.S.S., Nuffield Department of Industrial Health, University of Durham, King's College, Newcastle-upon-Tyne

The isolation of a red crystalline anti-pernicious-anaemia factor from liver was achieved almost simultaneously by Rickes, Brink, Koniuszy, Wood, and Folkers (1948) in America, and by Lester Smith and Parker (1948) in Great Britain. American workers were aided greatly by microbiological assays (Shorb, 1948), whereas in Britain attention was concentrated on testing each fraction in patients with pernicious anaemia in relapse. The 84 clinical tests begun in 1946* which guided Lester Smith's purification to the final stage of crystallization are of little medical interest and will not be described.

This report concerns only the pure crystalline material isolated by Lester Smith in Glaxo Laboratories, Greenford, which has proved to be identical with vitamin B_{12}. Chemical and physical properties are reported elsewhere by Lester Smith (1948), and by Fantes, Page, Parker, and Lester Smith (in the press).

Material and Methods

The 53 cases selected had the usual diagnostic features of pernicious anaemia, including megaloblastic marrow and histamine-fast achlorhydria. A few patients had relapsed after stopping treatment, but most had never been treated.

To limit the intake of extraneous haematopoietic factors during the initial test periods, meat, poultry, offal, meat products, yeast products such as "marmite," eggs, fresh fruit, and vitamin preparations were excluded from the diet, which contained white or National flour, processed cereals, sugar, jam or syrup, dried fruit, vegetables, butter and other fats, white fish, cheese, and 1 pint (570 ml.) of milk daily.

Reticulocytes were counted daily by a wet method using brilliant cresyl blue. Haemoglobin was determined by the cyan-haematin method of King and Gilchrist (1947). Red blood cells were counted every five days with N.P.L.-tested pipettes on a Bürker haemocytometer. Blood was diluted 1 in 200 with Hayem's fluid and at least six areas 1 by 0.05 mm. were counted. A test designed to measure the accuracy of counts by taking morning and afternoon specimens in 10 patients with anaemia showed that the standard error was ±6%.

For a control period of 7 to 10 days treatment was withheld so that patients showing signs of spontaneous remission could be excluded. A shorter control period was permitted if anaemia increased rapidly. A few cases were rejected because of intercurrent illness and one because of hypoplasia of the marrow. Also excluded were results rendered invalid by deterioration of vitamin B_{12} in very dilute solution (1 μg. per ml.)—a difficulty which has since been overcome.

Vitamin B_{12} was given intramuscularly as a single dose. Doses were graded logarithmically from 1.25 to 160 μg. An extra group was given 6.5 or 7.5 μg. (mean 7.2) because a level of dosage between 5 and 10 μg. was then believed to be critical (see later).

Patients with red blood cell counts above and below the mean level of 2,000,000 per c.mm. were, so far as possible, distributed equally in the groups receiving low, medium, and high doses.

Results

There were no unpleasant side effects, and sensitization to vitamin B_{12} was not encountered. The magnitude of the haematopoietic response was gauged partly from the reticulocyte crisis, but mainly from the rate of increase of red blood cells. A summary of 73 responses in 53 patients is given in Table I. An example is shown in Fig. 1.

TABLE I.—*List of All Responses*

	Dosage in μg.	Reticulocyte Response (%)	Red Blood Cell Counts (Millions per c.mm.) at Days Indicated

The highest count is in black figures. In a few instances counts recorded at 20 to 30 days were made a day or so before or after the time indicated. P.T. = previous transfusion. P.I. = previous injection; a number in brackets indicates the previous response; where no number appears the previous injection was of material not referred to in this paper (see under "Increase of Red Blood Cells" below.

* This freak response is excluded from calculations for Figs. 4 and 5 and Tables II and IV.

*In the early stages of this investigation some additional tests were carried out in Stobhill Hospital, Glasgow, by Dr. J. R. Lauckner, whose co-operation is gratefully acknowledged.

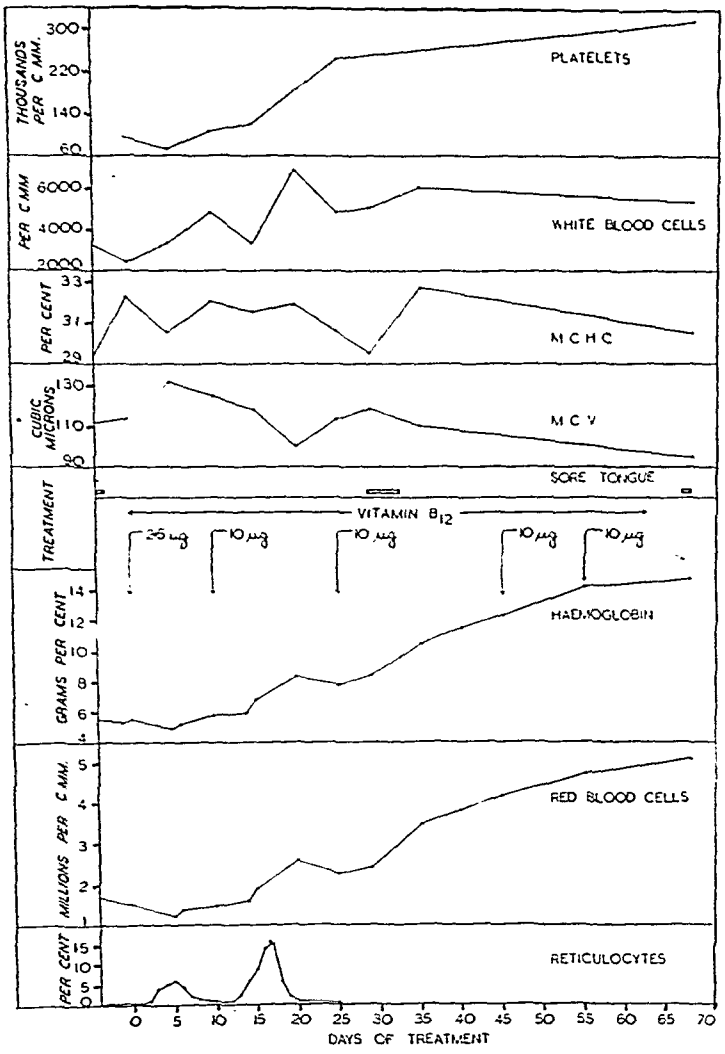

FIG. 1.—Response to repeated injections of Vitamin B_{12} in a patient with pernicious anaemia.

Reticulocytes

Reticulocytes usually began to rise on the second or third day, reaching a peak on the fifth or sixth day (counting the day of treatment as 0). There was a definite association between high dosage and early reticulocyte peak. *With large doses—20 to 160 µg.*—the peak usually occurred on the fifth day; with doses below 10 µg. the peak was usually on the sixth or occasionally the seventh day.

Reticulocyte responses of 39 patients, none of whom had had previous transfusion or injection, were compared with an "expected" response based on results to liver extract given intramuscularly (Isaacs and Friedman, 1938). Fig. 2 shows the actual responses at each initial red blood cell count. In Fig. 3 results are expressed as percentages of the expected response. Individuals varied widely in their response to a given dose. In more than 50% (10 out of 17) of the patients who received doses of 10 µg. and upwards the expected response was exceeded, whereas with smaller doses (1.25–7 µg.) this response was seldom attained (four times in 22 patients). A high reticulocytosis was not always the precursor of a satisfactory rise of red blood cells, confirming previous criticisms of the reticulocyte response as a measure of potency (Murphy, 1933; Ungley, 1936; Della Vida and Dyke, 1942; Fullerton, 1945).

Increase of Red Blood Cells

A better yardstick was the rate of increase of red blood cells. This depended not only on the dose of vitamin B_{12} but also on the initial count, and these factors varied independently of one another. Thus a formula became necessary to judge whether rates of increase were satisfactory or not.

For its construction we needed more data than were provided by the first responses in the 40 patients who had had no previous treatment. We had to decide whether to include certain additional data—namely, nine responses in patients who had been transfused with a small number of red blood cells, the survival of which could be followed by differential agglutination (Dr. Walker), and 24 responses in patients who had previously received small amounts of vitamin B_{12} (20 of them in the course of this trial). Such responses were not included unless there had been a satisfactory control period of seven to ten days of stationary or falling counts, as described under "Material and Methods" above. Where doubt existed a marrow puncture was performed and a further injection was given only if the marrow was megaloblastic.

In the nine transfused cases the average increase in the patient's own red blood cells in 15 days was 1,470,000, compared with an "expected" average increase of 1,400,000 calculated by the formula given below.

In the 24 patients who had relapsed after small amounts of vitamin B_{12} the average increase of red blood cells in 15 days was 1,220,000, whereas the expected average was 1,250,000.

In the 33 cases in these two groups the actual average increase was 1,290,000 compared with an "expected" increase of 1,290,000. Although, as described below, the "expected" increase has been calculated from a group of 63 patients which includes these 33, it is apparent from the above averages that the 30 patients who did not receive any previous treatment could not have differed significantly from the 33 patients who had had previous treatment. It was therefore considered justifiable to include the latter in the trial and to deal with them as normal cases. They are identified in Table I by P.I. (Previous Injection) and P.T. (Previous Transfusion). This neither assumes nor proves that such past treatment never has a serious effect on the rate of increase of red blood cells, but implies that such effects, if present, could be ignored in this series.

In all there were 73 satisfactory tests in 53 patients available for analysis.

Increase of Red Blood Cells in 15 Days

Increase of red blood cells in 15 days was the most useful criterion of response. Della Vida and Dyke (1942) have shown that the average weekly increase over the first two weeks of treatment depends on the initial level and varies inversely with it. Thus patients with fewer red blood cells at the beginning of treatment respond more rapidly than those who have higher counts, and conversely.

For each group of patients receiving similar doses a line was calculated by methods comparable to those of Della Vida and Dyke, and in every case, except for those receiving 2.5 µg., there was a marked relationship between the 15th-day increase and the initial count. But individually

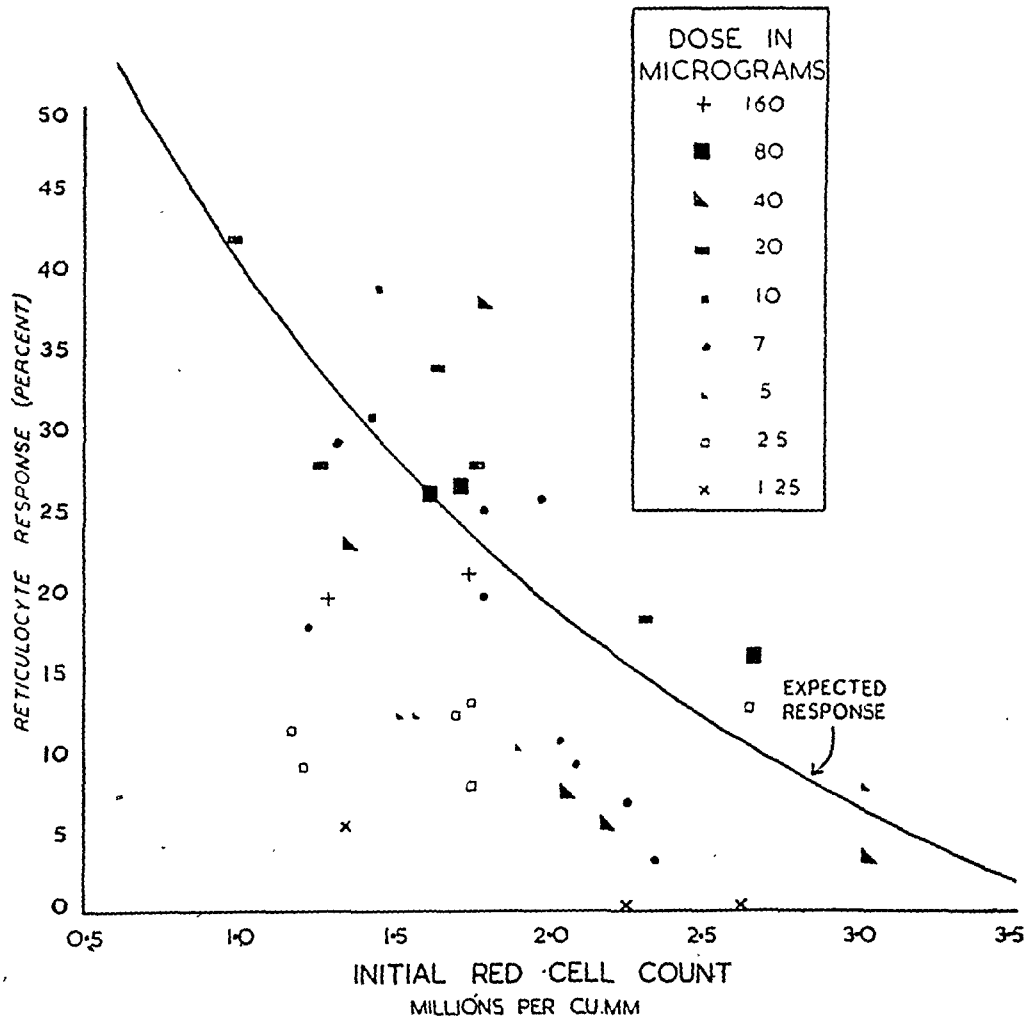

FIG. 2.—Reticulocyte responses (peak) in 39 patients to their first injection of vitamin B_{12} compared with expected response to liver extract calculated from formula of Isaacs and Friedman (1938).

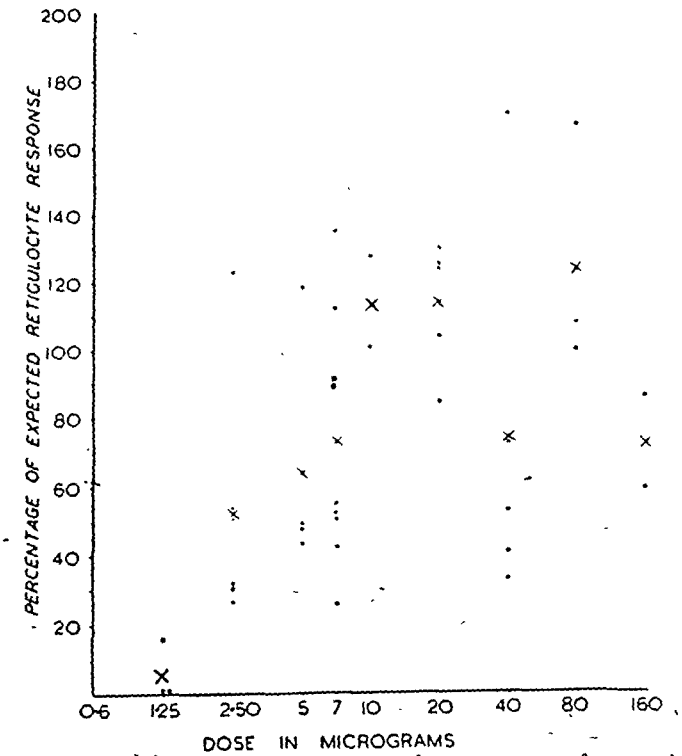

FIG. 3.—Reticulocyte response expressed as percentage of expected response. Crosses indicate the mean response at each level of dosage. Doses are spaced logarithmically.

none of these relationships could be considered statistically significant, because of the few cases involved, the largest group being 14. It was therefore necessary to calculate a formula making allowances for the differences in dosage and differences in initial blood counts at the same time.

The problem was simplified when it became apparent that over a certain range of dosage (5–160 μg.) the response varied according to the logarithm of the dose. (In practice this means that doubling the dose produces a constant increase in response.)

Out of 64 cases* receiving 5–160 μg. 63 were therefore used to calculate the formula by methods of multiple correlation, giving the following results:

$I_{18} = 1.008 - 0.153\ E + 0.245\ D - 0.017\ E \times D.$

Where I_{18} = Increase in red blood cells (millions per c.mm.) on the 15th day.

E = Initial red blood cell count (millions per c.mm.) on the day of injection.

D = Dose on a logarithmic scale—e.g. (5 μg. = 1; 10 μg. = 2; 20 μg. = 3; 40 μg. = 4)

The increases that may be expected according to this formula are given in Table II. and the lines have been superimposed upon Fig. 4.

This formula is applicable only for doses between 5 and 80 μg.—or possibly 160 μg.—and for patients whose initial

E = Initial red blood cell count in millions. I_{18} = Increase in red blood cells on the 15th day. D = Dose on a logarithmic scale (5 = 1; 10 = 2; 20 = 3; 40 = 4; 80 = 5).

The error made in using these tables will be less than the Standard Deviation in about 68% of all individual cases.

*Case 14 was excluded, as the response was most exceptional.

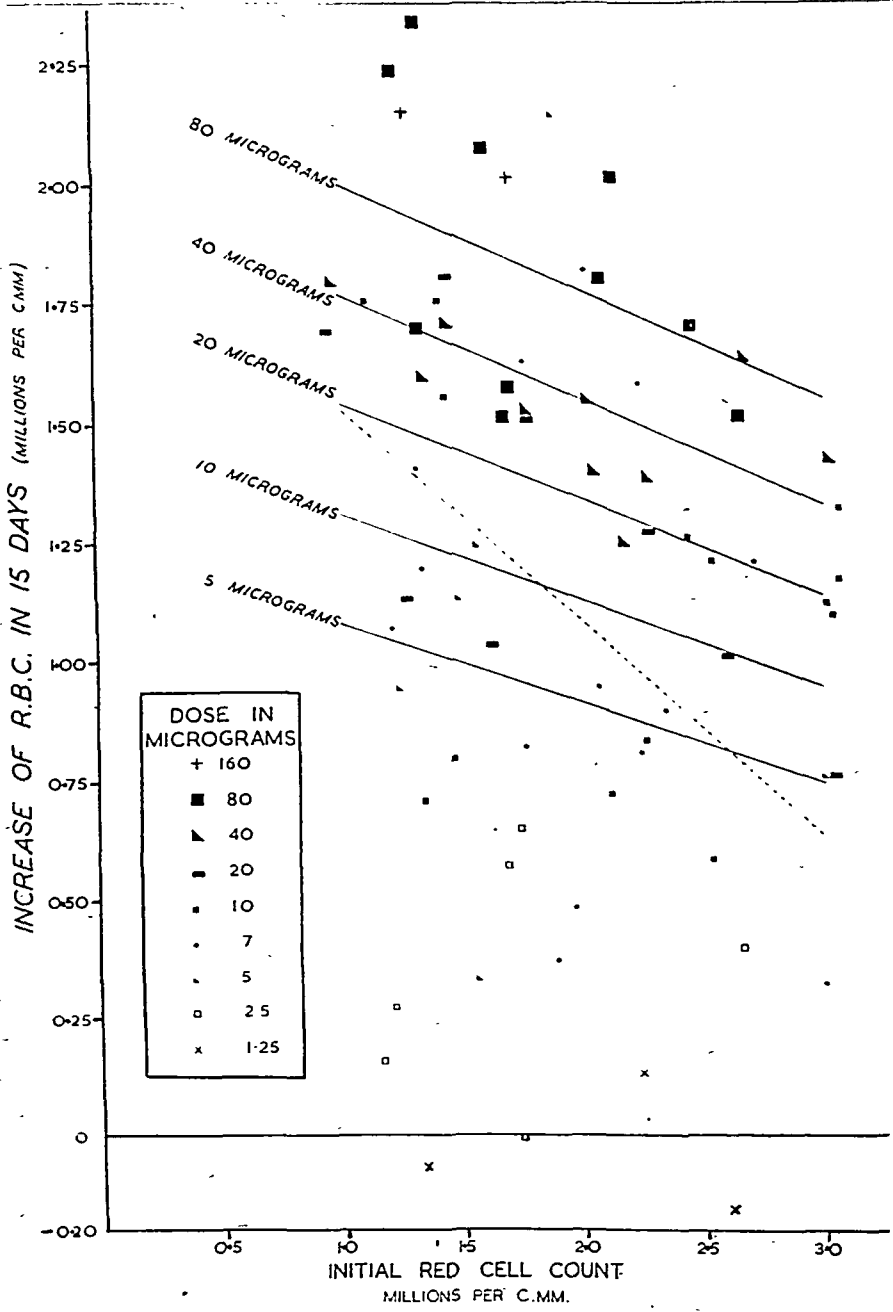

FIG. 4.—Actual increase of red blood cells in 15 days in 73 instances after vitamin B_{12}. The lines are calculated from a formula which takes account of dosage and initial red blood cell count. The dotted line corresponds to the formula of Della Vida and Dyke (1942) for "average" responses to liver extract.

red blood cell count lies between one and three millions per c.mm. Patients vary considerably in their response to treatment, but only 32% of responses will differ from the figures given in Table II by more than ±330,000. For groups of patients, however, the *average* increase of a group will be more accurate (e.g., for a group of 10 cases the average increase will usually be forecast by Table II with an accuracy of ±100,000).

The following is a brief explanation of the meaning of the formula, simplified by omitting the slight correction for the factor E×D. If a patient has an initial red blood cell count of 2,000,000 and is given an injection of 10 μg., the increase in 15 days will be about 1,120,000, making his actual count on the 15th day 3,120,000. For every doubling of the dose in the range 5 to 80 μg. there will be an additional increase of about 220,000, so that the increase in 15 days if the patient had received 20 μg. would be 1,340,000, and if 40 μg., 1,560,000. Similarly, for every million cells above 2,000,000 at the initial count the 15-day increase will be reduced by about 200,000, so that the increase for a patient with an initial count of 3,000,000 receiving 10 μg. is about 920,000. Similarly, for every million cells below 2,000,000 there will be an additional increase of about 200,000, so for a patient with an initial count of 1,000,000 the increase would be about 1,320,000 per c.mm.

The expected response found by Della Vida and Dyke for their "average" group was attained in our series by doses in the region of 10 μg., and only in this limited sense can amounts of this order be regarded as the "minimal effective dose" (Ungley, 1948b).

To check the validity of the formula the expected increases in 15 days were calculated for all 63 patients and compared with the actual increases obtained. The differences between these figures are given in Table III, where it will be noted that in over three-quarters of all the cases the error was less than 400,000. (The standard deviation of this table is ±320,000, which corresponds with that quoted in Table II.)

Dosage Response Curve Based on Increase of Red Blood Cells in 15 Days

The basic assumption made in calculating the formula was that the mean response to a given dose was proportional

to the logarithm of the dose. While this is a justifiable assumption over a given range, it is unlikely to be true over the total range of possible doses.

It was therefore necessary to examine the assumption more closely to see if it was justifiable and at what stage it broke down. Accordingly, the difference between actual and expected increases was calculated for each case; for doses outside the range of Table II the formula was extrapolated. The mean difference for each dose group is given in Table IV and Fig. 5.

TABLE IV.—*The Mean Difference Between Observed and Expected Increase in 15 Days*

Dose in μg.	No. of Cases	Mean Initial R.B.C. (Millions per c.mm.)	Mean Difference (Millions per c.mm.)
1·25	3	2·06	−0·52

160·0	2	1·49	−0·02

*i.e., excluding Case 14.

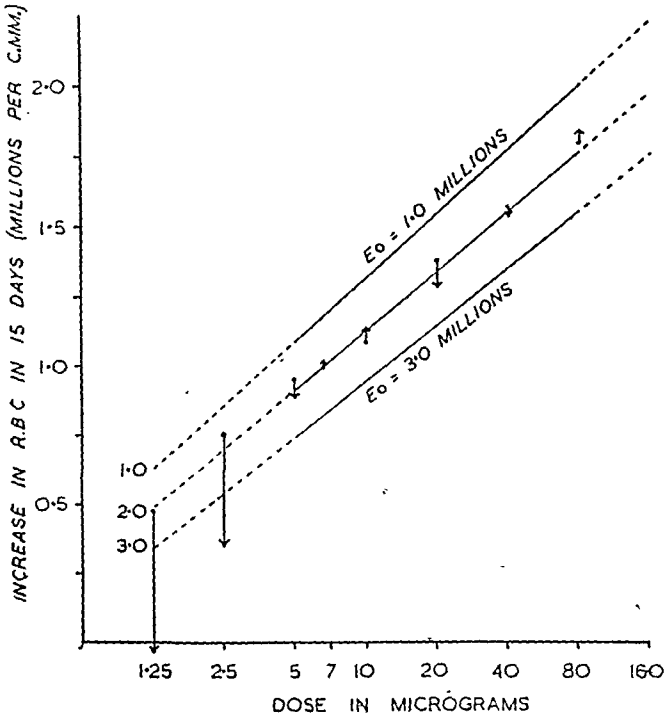

FIG. 5.—Dose response curve to graded doses of vitamin B_{12} (spaced logarithmically). Continuous lines = expected response according to formula in text. Difference between observed means and expected increase is shown by vertical lines. Dot = initial count; length of line = deviation from expected response; arrow shows whether deviation was above or below expectation. The relationship between response and log. dose did not hold for doses below 5 μg.

From Table IV it is apparent that doses below 5 μg. failed to produce a response proportional to the logarithm of the amount used. But for doses from 5 μg. to 160 μg. there is no significant departure from the logarithmic curve. Consequently, with the data available it may be concluded that between the stated limits the logarithmic is the most satisfactory approximation to the true dose response curve.

Below the stated limits a dose of 2.5 μg. produced fair reticulocytosis but a slow increase of red blood cells which was poorly sustained. The smallest amount given so far has been 1.25 μg., which produced slight reticulocytosis in one out of three cases with little or no increase in red blood cells in 15 days. Further tests are necessary to complete the curve and examine its behaviour for dosage levels at and above 160 μg.

An incidental finding is the considerable variation of the response, which is greater with small than with large doses (see Table VII). Variation in response might be due to a number of causes. Errors due to deterioration of vitamin B_{12} in solution and inaccuracy in measurement of dosage are believed to be small. Variation in the rate of absorption from the site of injection is probably significant only in so far as it affects the rate of excretion of vitamin B_{12} in the urine, itself probably an important factor. Individual requirements probably vary with such factors as age, sex, body weight, pyrexia, and metabolic rate. Another possible source of error is variable ingestion, utilization, and reserves of accessory haematopoietic factors, such as folic acid, which are present even in the restricted diet. The smaller variation in response after large doses suggests that they neutralize some of the sources of variability.

Increase at 5, 10, and 20 Days

Although the increase in 15 days was the most useful criterion for judging the potency of vitamin B_{12}, counts were also available for the 5th, 10th, and 20th days.

The increase in 5 days was slight—usually about 15% of the increase at 15 days (Tables V and VI). But precisely

TABLE V.—*Mean Red Blood Cell Counts During First 20 Days of Treatment*

160	13	60	100	103
All ..	17	81	100	110

the same characteristic variations were discernible, the increase varying with the logarithm of the dose and inversely with the initial count. The greatest rise was between the 5th and 10th days, by which time about 80% of the increase obtained in 15 days had occurred. Again, the same variables operated and had to be sorted out by a formula similar to that given above for the 15th-day counts. As a measure of response the 10th-day counts would have been nearly as useful as the 15th-day counts, but the chance of error was less with the greater increase in 15 days.

The 20th-day counts unfortunately were not complete in all cases, as some 21 patients who had not responded

well to treatment needed further injection before reaching the 20th day and had to be withdrawn from the trial. The remainder are therefore not a representative group, but are biased by the survival of the fittest. In this group the average increase by the 20th day was about 110% of the increase in 15 days.

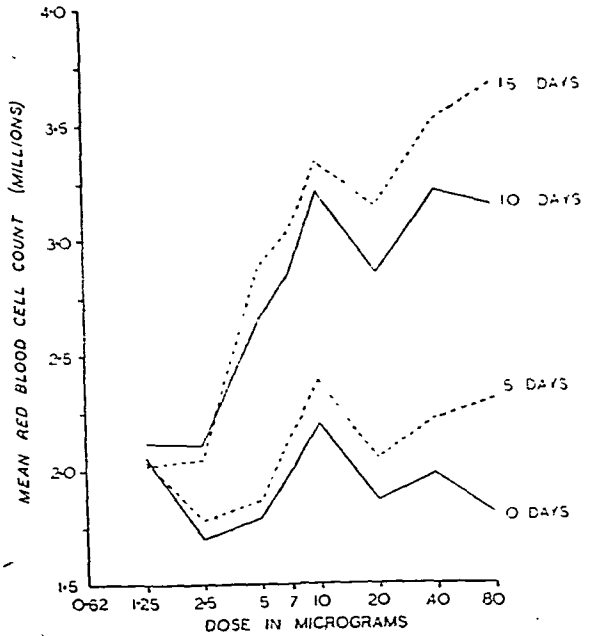

FIG. 6.—Mean red blood cell counts at fixed times after graded doses of vitamin B_{12} (spaced logarithmically).

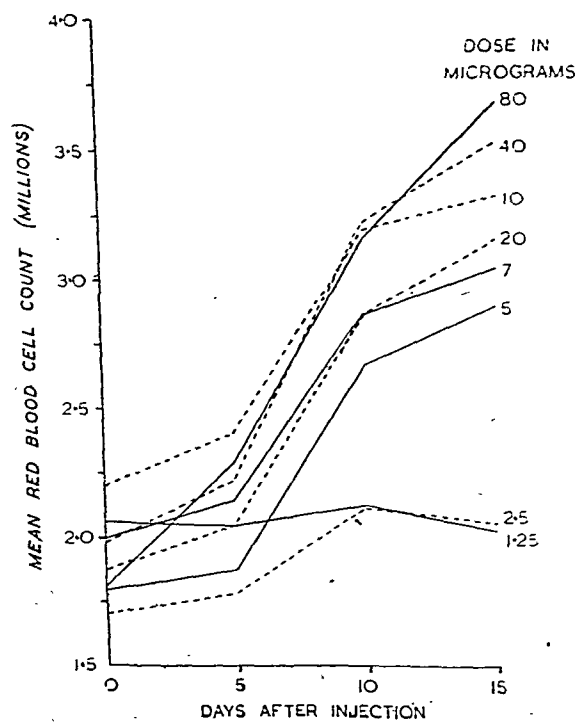

FIG. 7.—Mean response to graded doses of vitamin B_{12} (from same data as Fig. 6).

Fig. 6 shows the relationship between erythrocyte increase and dosage at various fixed intervals of time. In Fig. 7 the same data are arranged to show the behaviour of the erythrocyte counts over a period of 15 days for various fixed levels of dose. These figures show fairly clearly the relationship between time and dose and emphasize that higher doses produce responses which are not only greater but last longer. Fig. 8 shows the usual form of curve of increase of erythrocytes in the first three weeks after doses of 5–160 μg. (see Table VI).

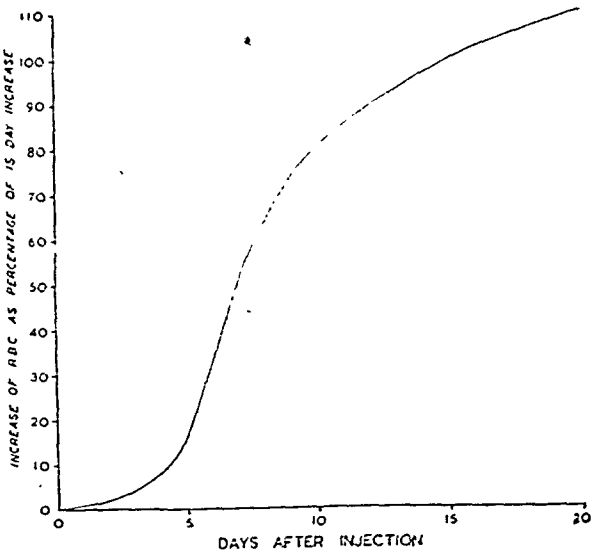

FIG. 8.—Proportion of increase of red blood cells which occurred in 5, 10, 15, and 20 days after a single dose of vitamin B_{12}. This form of curve holds true for most cases receiving doses of 5 to 160 μg. (see Table VI).

Total Dosage to Complete Remission

The amount of vitamin B_{12} required to raise the red blood cell count above 4,500,000 in 32 cases varied from 15 to 140 μg. and the time from 15 to 118 days. Individual findings are not recorded, since variations depended partly on the size and spacing of the doses. If red blood cell counts were allowed to fall before subsequent doses were given, then more time and material were required for complete remission. Moreover, remission was attained less economically with a single large dose than with the same amount of material given in divided doses at fortnightly intervals. Daily requirements for vitamin B_{12} could not be determined accurately from such data.

Other Findings

Changes in the *bone-marrow* from megaloblastic to normoblastic erythropoiesis after liver extract are described by Davidson, Davis, and Innes (1942) and after Lester Smith's non-crystalline red-pigmented material by Lorriman (1948). Similar changes following crystalline vitamin B_{12} were observed in the present series by Drs. G. Lorriman and R. B. Thompson (personal communication).

Initial *white blood cell counts* before treatment in 32 patients ranged from 1,500 to 8,300 (mean 4,300 ± S.E.260 per c.mm.). When remission was attained (red blood cells 4,500,000 per c.mm. or over) white blood cell counts in these patients ranged from 4,000 to 8,800 (mean 6,200 ±

170 per c.mm.). *Platelet counts*, too, usually rose to normal levels; Fig. 1 shows a typical response. Counts before treatment in 42 patients ranged from 20,000 to 283,000 (mean 105,500 ± 7,000). Counts 1 to 12 weeks later (mean 3.5 weeks) ranged from 120,000 to 560,000 (mean 305,500 ± 16,000). The difference between means both for white blood cells and for platelets is highly significant.

Within the first few days there was a dramatic increase in appetite and well-being, followed later by a gain in weight. Disturbances such as nausea, vomiting, and diarrhoea were relieved.

Soreness of the tongue usually disappeared within a few days, recurring only if the effects of an injection were allowed to wear off. Three exceptions are mentioned under "Maintenance." Clean smooth tongues became partially or completely repapillated and sometimes furred.

Neurological and certain other findings are discussed below.

Maintenance

Excluding cases with subacute combined degeneration, 21 patients were treated long enough (6 to 15 months) to give some indication of requirements for maintenance. The standard dose was 10 μg. every two weeks, although in two instances the interval was lengthened to three and four weeks, and in one the dose was increased because of sore tongue. To simplify further discussion the exceptions will be considered first.

Six women showed evidence of iron deficiency after 8 to 15 weeks, with low mean corpuscular haemoglobin concentration (M.C.H.C.); normality was restored by a course of ferrous sulphate.

Three of these women and one man mentioned below had isolated red blood cell counts of just below 4,000,000 per c.mm. in the maintenance period. In one of the women the low count followed an attack of influenza; the man had intermittently a sore tongue and some macrocytosis (mean M.C.V. 96.5 c.μ; range 90.4 to 101.6 c.μ), indicating that his requirements were not completely met by 10 μg. a fortnight.

Another patient complained of very slight soreness of the tongue at each attendance. A third had intermittently a red sore tongue, which was not relieved even when doses were stepped up to 80 μg. Neither of these two patients had abnormal blood findings during the maintenance period.

The mean values mentioned below were derived from the sum of all findings for each patient (including the exceptional cases) after red blood cells first reached 4,500,000 per c.mm.

Mean red blood cell counts ranged from 4,480,000 to 5,120,000 (mean 4,950,000). Mean haemoglobin values ranged from 11.1 to 14.7 g. (mean 13.8 g.) per 100 ml.

Except in the six women who developed iron deficiency, haemoglobin increased at a rate adequate to maintain a normal M.C.H.C. Mean values for M.C.H.C. for all cases ranged from 28.1 to 34.8% (mean 30.9%).

By the time the red blood cell counts had reached 4,500,000 the M.C.V. had usually fallen to normal (76 to 94 c.μ). Mean values during maintenance ranged from 81.1 to 96.5 c.μ (mean 89.6 c.μ). A few patients had isolated values of 96 to 99 c.μ, but only the one man already mentioned had any suggestion of persistent macrocytosis.

Findings in eight patients with subacute combined degeneration who received much larger doses of vitamin B_{12} (see below) are of interest. Mean red blood cell counts ranged from 4,850,000 to 5,550,000 per c.mm.; mean haemoglobin levels ranged from 13.8 to 15.4 g. per 100 ml M.C.H.C. was always within the normal limits; so was M.C.V., apart from one isolated reading of 96.7 c.μ.

Neurological Manifestations

Twenty-one patients in this series have been followed for six to 15 months and others for shorter periods; neurological manifestations improved or remained unchanged and fresh symptoms have not developed.

More direct evidence of the efficacy of vitamin B_{12} against the neurological manifestations of pernicious anaemia was obtained by treating established cases of subacute combined degeneration (Ungley, 1948a, 1949). The first patient began treatment with Lester Smith's red but not yet crystalline material in December, 1947, changing to crystalline vitamin B_{12} six months later. Now eight patients have received pure vitamin B_{12}—usually 40 μg. a week—for a minimum of 10 months. Using a quantitative method of assessing neurological status, significant improvement was demonstrated in each case. Comparison with 44 patients treated before the war showed that vitamin B_{12} was as effective as liver extract—crude or refined—in the treatment of subacute combined degeneration (Ungley, 1949).

Routine dosage of vitamin B_{12} must cover wide individual variations in requirement and maintain reserves. Uncomplicated cases without neurological involvement may be given 40 to 80 μg. initially, followed by 20 μg. weekly for three months and 30 μg. every three weeks thereafter Patients with subacute combined degeneration should receive weekly at least 40 μg. for six months and 20 μg thereafter. Some will need more: at the least sign of relapse—lingual, haematological, or neurological—or if infection develops, dosage should be temporarily doubled or trebled.

Our findings amplify earlier reports on the effect of vitamin B_{12} given parenterally in pernicious anaemia (West. 1948; Ungley, 1948a, 1948b, 1949; Hall and Campbell, 1948; Spies, Stone, Kartus, and Aramburu, 1948; Berk, Denny-Brown, Finland, and Castle, 1948; Bethell, Meyers, and Neligh, 1948; Spies, Suarez, Garcia Lopez, Milanes, Stone, Lopez Toca, Aramburu, and Kartus, 1949; West and Reisner, 1949).

Subsequent papers will describe the effects of vitamin B_{12} administered via the alimentary tract; its effect in non-Addisonian megaloblastic anaemias; its effect in certain cases of megaloblastic anaemia showing rapid elimination of transfused red blood cells; and the effect in pernicious anaemia of factors related to vitamin B_{12}, including thymidine and Lester Smith's slow-moving red component.

Summary

Seventy-three responses to single doses of vitamin B_{12} injected intramuscularly were observed in 53 patients with pernicious anaemia in relapse.

Doses were graded logarithmically from 1.25 to 160 μg Conclusions are based on the means of a number of responses at each dose level. Reticulocyte responses were compared with the "expected" response to liver extract according to Isaacs and Friedman (1938), but a better yardstick was the increase of red blood cells in 15 days.

While doses of 1.25 μg. had little or no effect, 2.5 μg. produced a definite but small response. Responses to 5 and 7 μg. were on average somewhat below, and to 10 μg. just up to expectation, both in respect to reticulocytes (Isaacs and Friedman, 1938) and to increase of red blood cells in 15 days (Della Vida and Dyke, 1942, formula for "average" group).

Only in this limited sense can 10 μg. be regarded as a minimal effective dose. Larger doses produced still greater increase of red blood cells in 15 days, the mean response being roughly proportional to the logarithm of the dose, at least in the range 5 to 80, or possibly even 160 μg. From a formula devised to express this relationship the expected response to any dose within the range was calculated. Most of the responses actually obtained did not differ from the expected response by more than 330,000 per c.mm.

Further tests at high and low levels of dosage are needed to complete the dose response curve, which will probably be sigmoid in form, rising gradually, then steeply, from the threshold dose, and flattening out to a horizontal level when supramaximal doses are reached.

Maintenance doses of 10 μg. of vitamin B_{12} every two weeks were satisfactory in 18 out of 21 patients followed for six to 15 months. The exceptions were three patients whose sore tongue was not completely relieved, one having macrocytosis in addition. Six women developed iron deficiency at eight to 15 weeks, relieved by ferrous sulphate.

Fresh neurological symptoms did not develop. Direct evidence of an effect in subacute combined degeneration is published elsewhere (Ungley, 1949).

I am indebted to medical, nursing, technical, and clerical members of the staff for their co-operation, and to general practitioners who referred untreated cases of megaloblastic anaemia: further progress in this field depends on their continued help. I am also indebted to Dr. E. Lester Smith and his colleagues in the Research Division of Glaxo Laboratories Ltd., Greenford, who prepared and supplied all the crystalline vitamin B_{12} used in these investigations.

APPENDIX

It was necessary to calculate from the data in Table I formulae which would give the number of red blood cells to be expected in a given patient after a given dose.

Regression lines were calculated between increase in red blood cells at 15 days (I_{15}) and the initial count (E) for each dose. These were as follows (Table VII):

Dose (μg.)	No. of Cases	Regression Line I_{15} in millions	Correlation	Std. Dev. of I_{15} in millions
2·5	6	$I_{15} = 0{\cdot}162 + 0{\cdot}101\ E$	+0·23	0.45
5·0	5	$I_{15} = 1{\cdot}039 - 0{\cdot}091\ E$	−0·18	0.50
7·2	14	$I_{15} = 1{\cdot}487 - 0{\cdot}226\ E$	−0·25	0.45
10·0	14	$I_{15} = 1{\cdot}432 - 0{\cdot}130\ E$	−0·26	0.34
20·0	8	$I_{15} = 1{\cdot}935 - 0{\cdot}339\ E$	−0·57	0.35
40·0	10	$I_{15} = 1{\cdot}824 - 0{\cdot}149\ E$	−0·55	0.14
80·0	10	$I_{15} = 2{\cdot}362 - 0{\cdot}285\ E$	−0·47	0.27

These lines indicate a consistent relationship between low initial red blood cells and high response at 15 days for all doses between 5 and 80 μg. There is, moreover, a suggestion that the dosage effect is on a logarithmic scale.

A fresh regression line was calculated for doses between 5 and 80 μg. for three variables I_{15}, E, and D, where D was the dose on a logarithmic scale—i.e., 5 μg.=1; 10 μg.=2; 20 μg.=3; 40 μg.=4; 80 μg.=5. (On this scale the intermediate dosage of 7.2 μg. corresponded to 1.5.) This gave formula 2:

$$I_{15} = 1.168 - 0.199\ E + 0.193\ D$$

Number of cases = 61

Corrected correlation between I_{15} and D = +0.60

" " " I_{15} and E = −0.31

Standard deviation of I_{15} = 0.33 millions

This formula, used for preparatory work on dosage response, compels the dosage lines to run parallel, whereas perhaps they should converge. To test this hypothesis another formula was calculated in which a fourth factor was introduced, C=D×E. If there was a tendency for the lines to converge this would be apparent in the value of C. At this stage further data were available for two cases receiving 160 μg., and as these appeared to fall accurately on the extrapolation of formula 2 they were included in the calculation of formula 3, which was as follows:

$$I_{15} = 1.008 - 0.153\ E + 0.245\ D - 0.017\ D \times E$$

Number of cases = 63

Standard deviation of I_{15} = 0.33 millions.

This is the formula used in the text.

The drawing up of a series of measures designed to strengthen health administrations in underdeveloped countries in the fight against tuberculosis is one of the main results achieved by the Expert Committee on Tuberculosis of the World Health Organization, which recently concluded a five-day session in Copenhagen. The importance of training health personnel in underdeveloped areas was stressed repeatedly by the experts. They pointed out that the World Health Organization could be of great assistance in setting up centres to train local personnel in all phases of tuberculosis control work and to serve as demonstration centres for medical and auxiliary personnel of the area. The committee further suggested that WHO might give useful information on certain types of hospitals which could be set up in a relatively rapid and economical way. Health education was recognized by the committee as an essential tool in tuberculosis control. It was urged that WHO should encourage national and international voluntary organizations to inform the public on all aspects of the tuberculosis programme carried out in a particular country with the purpose of securing active support for it. The value of tuberculin-testing and of B.C.G. vaccination as the only practical way known so far of producing specific resistance against tuberculosis was reaffirmed by the committee. Further, it was emphasized that B.C.G. immunization could be fully effective only if used as a part of a general programme in addition to the application of other available preventive measures. Mass vaccination with B.C.G. was specially recommended for countries with high tuberculosis infection and mortality rates. In connexion with the B.C.G. programme the committee heard a report on the work and plans of the research office which has been set up by WHO in Copenhagen to evaluate the results of tuberculin-testing and B.C.G. vaccination. The results to be expected from this WHO research group will be of great value to future planning of anti-tuberculosis campaigns on a world-wide basis.

VITAMIN E IN THE MENOPAUSE*

BY

HUGH C. McLAREN, M.D., F.R.F.P.S., F.R.C.S.Ed. M.R.C.O.G.

First Assistant, Chair of Obstetrics and Gynaecology, University of Birmingham

Menopausal flushing and sweating can usually be controlled by oestrogens, but the stimulating effect of these hormones on the genital tract and breasts sometimes contraindicates their use—for instance, after radium treatment of cancer or before cessation of menstruation. Although oestrogens promote cancer development in animals there is so far no proof that they do so in man (Gemmell and Jeffcoate, 1939 ; Gardner, 1947). Nevertheless, "cancer-like" areas are quite often a troublesome finding in curettings from patients whose oestrogen-withdrawal bleeding has necessitated curettage (Gusberg, 1947).

Vitamin E was first used by Evan Shute (1937) to control flushings, and several confirmatory reports have followed (Shute *et al.*, 1938 ; Hain and Sym, 1943 ; Christy, 1945 ; Ferguson, 1948 ; Finkler, 1949). In this study special attention has been paid to the genital tract to ascertain if vitamin E is inert and therefore a substitute for oestrogens or stilboestrol in cases in which stimulation of the genital tract is undesirable.

*Read before the Birmingham and Midland Obstetrical and Gynaecological Society on March 31.

The Investigation

Clinical Material.—In view of the cost (£7 per case), treatment was given only to patients seriously disabled by drenching sweats, flushings, loss of sleep, and so on. The incidence of severe flushing after cessation of menstruation is about 17%, while after radium or surgical castration the figure is 50% (McLaren, 1941). Vitamin E in the form of alpha-tocopherol ("ephynal") was given to 47 patients with severe flushings ; these included four regarded as new cases, although in fact they had relapsed after successful treatment with vitamin E. Forty cases had not been previously treated, while three had resisted stilboestrol. The 47 cases fall into the following categories :

	Cases
Radium menopause (two years approximately)	25
Deep *x*-ray (one year approximately)	9
Hysterectomy and double oophorectomy	10
Hysterectomy and one ovary	2
Spontaneous menopause	1

As a control before vitamin E, 18 cases were treated as follows. After completion of her case history and pelvic examination the patient was given blank tablets and a card to record the number of flushes at each period of the day

TABLE I.—*Effect of Vitamin E on Flushing*

No. and Class	Vitamin E (mg.)	Days	Result	Blanks before Treatment		Blanks after Treatment		Spontaneous Relapse

Spont. M. = Spontaneous menopause. *X*-ray = *X*-ray menopause. Castrate = Hysterectomy and bilateral salpingo-oophorectomy. 1 ovary = Hysterectomy and unilateral salpingo-oophorectomy. Rad. M. = Radium menopause. Part cure = Patient not completely relieved. Bracketed cases = Relapsed and retreated cases.

After intervals up to 42 days (average 19 days) only one case was cured (No. 647), while another was somewhat improved but was still in need of treatment.

The results of treatment of flushing by vitamin E are shown in Table I : 23 were completely cured, 7 were markedly improved, and 17 were failures. The dosage given was as follows : lowest, 1,400 mg. ; highest, 60,000 mg. ; average 18,500 mg.

Effect of Placebos.—Of 23 cured or improved cases, 22 were given placebos for periods varying from 14 to 106 days (average 35 days). Fifteen cases (68%) maintained their improvement, while seven relapsed. Flushing reappeared in four and partially reappeared in two cases, while 16 (73%) maintained the cure. Of 17 cases questioned up to a year after completion of treatment 12 had relapsed partially or completely, but five were completely free from symptoms. No information was available from the remaining six cases.

Analysis of Failures.—There was apparently no special "type" of menopause resistant to treatment—viz., radium menopause, 10 cases; hysterectomy and double oophorectomy, three cases; deep x-ray, three cases; spontaneous menopause, 1 case. In an attempt to overcome the resistance to treatment doses up to 60 g. (average 20.745 g.) were given over an average period of 36 days, but without success. The 17 "failures," however, were quickly cured of their flushings by small doses of stilboestrol.

Vitamin E and Sex Function

A recent survey of the effect of the radium menopause on sex function led to the belief that it speedily causes many patients to lose their normal libido and the ability to achieve the orgasm. Ten out of 100 cases, moreover, suffered from dyspareunia after radium (McLaren, 1949).

It was impossible to interview every patient, and often the information was quite obviously inaccurate—e.g., when the patient alleged satisfactory coitus yet on examination proved to have a painful lesion of the vulva or vagina. Accordingly only 22 out of 43 patients were considered to be giving reliable evidence, but from this number we concluded that vitamin E had little effect in restoring libido or on the achievement of orgasm. As will be described later, vitamin E has a slow effect in curing painful senile lesions in the genital tract, and to this extent it must contribute to improved sexual relations, although in this it does not compare with stilboestrol.

Effect of Vitamin E on the Genital Tract

The clinical material was drawn from patients who some two years previously had had the menopause induced by radium. Senile lesions in the genital tract are then quite common—e.g., bleeding spots were observed in the vagina on speculum examination in 11 out of 68 patients whose ages averaged 45, an incidence which would not be unusual in normal women 15 or 20 years later (McLaren, 1941, 1949). We therefore had the opportunity of testing the curative effect of massive doses of alpha-tocopherol on these and other senile genital lesions. Cell-smears were also studied to ascertain if the drug was in fact inert or caused any cell division or differentiation.

Shute *et al.* (1938) and Shute (1942) have reported healing in a proportion of cases of senile vulvo-vaginitis after vitamin E, while Rubenstein (1948) and Finkler (1949) both comment on the inert or poorly developed type of vaginal smear which follows vitamin E as compared with the high degree of maturation of cells which follows stilboestrol.

In 28 to 112 days slow but definite healing was observed in four senile vulvar lesions, while two cases were unchanged (Table II). Case 134 will be reported under "toxic reactions," for dermatitis compelled us to stop treatment. In this case we first noted a remarkable softening of the indurated vulva, then a diminution in pruritus, and, finally, almost complete healing, which was still maintained a year later.

TABLE II.—*Effect of Vitamin E on the Vulva and Introitus*

No. and Class	Disease	Dose (mg.)	Days	Result
45 Radium menopause	Red introitus bled easily	8,400	82	Very much improved
134 Carcinoma of body	Vulvitis, pruritus, excoriation	38,680	112	Almost cured, but skin reaction. (See below)
269 Hysterectomy and 1 ovary removed	Red tender introitus	6,860	28	No improvement
293 Hysterectomy and bilateral salpingo-oophorectomy	Patches of red (raw) areas at vulvo-vaginal junction	28,750	110	Cured
355 Radium menopause	Red introitus, tender caruncle	5,600	35	No improvement
263 " "	Introitus red, tender periurethral oedema	3,360	35	Healed

Effect of Vitamin E on the Vagina

In all, 30 cases were examined by a Cusco speculum before and after treatment. Twenty-two normal cases were unchanged, showing no undue vascularity or "blueing" such as one normally sees after stilboestrol. The remaining eight cases (Table III) had senile vaginitis; of these,

TABLE III.—*Effect of Vitamin E on Senile Vaginitis*

No. and Class	Disease	Dose (mg.)	Days	Result
269 Hysterectomy and 1 ovary removed	Senile vaginitis	6,861	49	No effect; bleeding spots persisted
*45 Radium menopause	Senile vaginitis (acutely) inflamed	8,400	82	Healed; no red or bleeding spots
615 Subtotal hysterectomy and two ovaries removed	Senile vaginitis	42,000	42	Cervix healed; little effect in vagina
*46 Radium menopause	Mild vaginitis	5,110	102	Improved, but still several bleeding spots
*106 " "	" "	4,200	56	No effect
*112 " "	" "	3,360	28	Healed
263 " "	" "	3,360	35	"
293 Hysterectomy and two ovaries removed	Red vagina (split and bled with small speculum)	28,750	112	"

* "Spots" also present on the portio cervicis.

two were apparently the result of a simple speculum examination using 30% "dettol" cream. After prolonged treatment with alpha-tocopherol four were cured and four were only slightly affected. It is possible, however, that simple hygienic measures with sexual abstinence would also have affected a cure.

As in the case of the vulva, therefore, vitamin E has a slow healing effect, but in no way compares with stilboestrol as a healing agent in senile vaginitis.

Effect of Vitamin E on Vaginal Smears

Certain types of vaginal smears are capable of giving a fairly accurate forecast of the state of development of the underlying mucosa—for instance, after stilboestrol therapy in a 70-year-old woman adult flat squamae replace small immature cells and leucocytes. It is necessary, however, to set a limit on what can be "read" from vaginal smears. For instance, in a previous report 138 biopsies and smears were correlated, but only adult smears and senile (small-cell) smears gave an accurate forecast of the epithelial maturity or senility. The remaining and most numerous smears with large squamae, spinosum cells, and small (immature) cells could not be "read" with accuracy (McLaren, 1941). With these limitations in mind, and aware that only gross changes such as "stilboestrol effects" (or perhaps ovulation) (Papanicolaou and Traut, 1943) could be "read," 36 smears were taken. The classification III down to I represents grades of increasing senility.

Total number of vaginal smears	36	
Grade III, mainly squamae	1	Adult
Grade IIIM, menopausal clumping	12	Adult
" " mixed, spinosum, squamae, and deep cells	7	Increasing senility
" II (spinosum cells) (40 μ diam.)	9	Increasing senility
" I (small basal cells)	7	Increasing senility

TABLE IV.—*Changes in Vaginal Smears after Vitamin E*

No. and Class	Grade	Dose (mg.)	Effect
47 Radium menopause	IIIM (adult)	4,116	I—i.e., depressed
176 " "	III (full adult)	1,400	II?I—i.e., depressed
466 " " (*Figs.* 1, 2, 3)	Mixed	17,500	IIIM, "luteal clumps"—i.e., higher differentiation
736 *X*-ray menopause	II	14,000	IIIM—i.e., a higher differentiation
743 " "	Mixed	25,200	IIIM—i.e. (very full); almost stilboestrol effect; differentiated
615 Hysterectomy and both ovaries removed	II (vaginitis)	42,000	IIIM—i.e., a higher differentiation

Only six out of 36 smears therefore showed definite alteration in maturity, and this parallels the lack of clinical change after alpha-tocopherol. Case 47 (Table IV) had had dienoestrol up to the beginning of treatment with alpha-tocopherol, and the smears simply depict a sudden loss of ovarian hormone or its equivalent, dienoestrol. Case 466 is mentioned later, since here the development of an intensely clumped smear not only resembled a pregnancy smear but on laparotomy a luteal cyst was discovered (Fig. 4). The changes in Case 736 were quite sharp, so that a guess was hazarded that this patient might menstruate, and, as described below, this actually happened.

Effect of Vitamin E on the Cervix

Thirty-four speculum (Cusco) examinations following doses up to 60 g. of alpha-tocopherol failed to show any increase in bulk, softening of the portio, or increased mucus secretion. Four out of five cases with bleeding punctate spots on the portio, however, were cured by vitamin E; in three this was part of the general healing of the vaginal mucosa.

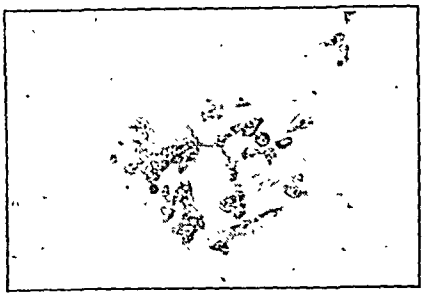

FIG. 1.—Case 466. Radium menopause one year. Small "castration" cells mixed with more mature squamae. *Stain:* Papanicolaou and Traut.

FIG. 2.—Case 466. After 4.5 g. vitamin E. Heaped up smaller cells with larger squamae emerging from deeper layers. This smear resembles mid-pregnancy or the "luteal" phase.

Twenty-six cell-smears were taken before and after treatment, but there was no sharp alteration with use of vitamin E. The motley collection of cells typical of a menopausal cervix persisted—namely, leucocytes, endocervical cells, long (120 μ) fibre cells, and so on. There was no sudden diminution in the number of cells and their replacement by clear mucus such as follows stilboestrol therapy.

FIG. 3.—Case 466. After 17.5 g. vitamin E. Haemorrhagic luteal cyst coexisted. Intermediate cells apparently being desquamated in sheets.

FIG. 4.—Case 466. After 17.5 g. vitamin E. Corpus luteum distended with blood.

It is clear, therefore, that neither the cervix nor its secretion or cytology is altered by massive doses of vitamin E. It may be, however, that just because it does not stimulate cell division and mucus secretion vitamin E may prove to be safer than stilboestrol in the control of flushings which follow irradiation of the pelvis.

Urethral Smears after Vitamin E

Although no patient had urinary symptoms, Hanley's (1944–5) work in menopausal urethritis and trigonitis, and Zuckerman's (1940) observations on the male macaque urethra, suggested that it might be worth while to observe the cytological changes in the urethra.

A dry swab often fails to pick up urethral cells, and only 21 specimens were obtained. A typical well-differentiated smear contains ovoid epithelial cells about 40 μ in diameter; free nuclei, leucocytes, and small clumps of flattened squamae complete the picture. Fourteen typical (differentiated) smears were not altered by vitamin E—i.e., there was no further building up or desquamation of the epithelium. The changes observed in seven smears are shown in Table V.

As in the vagina, therefore, there is no sharp reaction in all urethral smears, and it is possible that the changes observed were the result of faulty technique—e.g., in failing to pick up cells. Only in Cases 736 and 47 was a corresponding change observed in the vagina—namely,

TABLE V.—*Changes in Urethral Smears*

No. and Class	Dose E. (mg.)	Urethral Smear	
		Before	After
53 Radium menopause	3,360	Small undifferentiated cells	Larger, differentiated
45 " "	3,400	Degenerate epithelial cells (? poor fixation)	Loss of leucocytes (inflamed introitus also healed at this time)
47 " "	4,116	Normal smear	Degenerate epithelial cells. (Effect of loss of dienoestrol?)
736 X-ray menopause	14,000	Scanty cells	Abundant large differentiated cells
743 " "	25,200	Granular debris	Many adult transitional cells
754 " "	28,000	Scanty debris	Well-differentiated cells; free nuclei
466(b) Radium menopause	42,000	Debris	Adult cell smear

maturation, Case 736; senility, Case 47. From this small number of specimens, therefore, it seems possible that vitamin E may cause development and desquamation of the urethral epithelium, although in most cases no cellular alteration is detectable.

Case Reports

Dermatitis and Uterine Bleeding After Vitamin E

Case 1.—Mrs. A, aged 66, developed a generalized itching dermatitis which spared only her face. In the neck the skin became raised in silvery folds, but in the abdomen the rash was rather blotchy and red. Twelve years previously the patient had panhysterectomy with supporting vaginal radium for carcinoma of the corpus, and for a year previously she had suffered from intense pruritus. The vulva was excoriated and had many small areas of lichen simplex. Under vitamin E the vulvar condition almost completely healed. The labia majora and introitus became soft and elastic, but after 16 weeks (36,640 mg. alpha-tocopherol) the rash stopped treatment. The generalized skin condition took eight weeks to settle, but the vulvar pruritus and vulvitis did not relapse, and a year later the patient was practically symptom-free although on examination four very small areas of vulvar excoriation were present.

Post-menopausal Luteal Cyst

Case 2.—A widow aged 42 (No. 466) had radium menopause 10 months ago. Three months ago a 10-weeks course of stilboestrol (1 mg. b.d.) was completed with temporary control of flushing and no withdrawal bleeding. After 5.4 g. of alpha-tocopherol she had 12 days' uterine bleeding preceded by breast-tingling and dysmenorrhoea. Flushings, however, persisted almost unabated, and treatment was continued for 43 days, with control of her flushings. After 17 g. of vitamin E (49th day) she developed sudden right iliac pain with nausea and vomiting. Laparotomy revealed a normal appendix but a left luteal cyst distended with blood. The uterus on its peritoneal aspect resembled a coarse type of liver cirrhosis, being irregular and nobbly to the touch.

Histologically, the luteal cyst from the left ovary was of simple haemorrhagic type, measuring 2 in. by ¾ in. (5×1.8 cm.) (Fig. 4). The right ovary (10 months after radium) contained no recent follicles or corpora lutea but numerous corpora albicans. Vaginal smears: Figs. 1 to 3 show the movement in the cell pictures under vitamin E. No further uterine bleeding followed removal of the right and most of the left ovary, although flushings recurred and were once again controlled by vitamin E (31 g. in 35 days).

"Collapse" of the Breasts

Case 3.—(No. 725.) Aged 46. After 54 g. of alpha-tocopherol the patient complained that her breasts felt slack. Unfortunately we were unable to compare the size of the breasts before and after treatment, but it seems likely that little change in size had occurred. (They were small and pendulous.) No corresponding alteration in cell smear was observed.

Resumption of Menstruation

Case 4.—(No. 736.) Aged 44. *X*-ray castration one year ago. This patient began to menstruate five weeks after 14 g. of vitamin E. Unfortunately she also had completed a course of 20 mg. of amphetamine sulphate, so that it is doubtful which drug (if any) caused resumption of bleeding. Premenstrual curettings showed intense stromal vascularity and simple gland formation.

Comment

Vitamin E can apparently control severe menopausal flushing in more than 50% of cases, and, although not quite inert, its activity on the genital tract in no way compares with that of stilboestrol.

How vitamin E brings about its therapeutic effect on menopausal flushings is quite obscure, and will probably remain so until the mechanism which causes flushing is understood. This lack of knowledge of the therapeutic action of vitamin E applies to other fields of medicine (*Symposium on Vitamin E*, 1939; *Lancet*, 1949) where alpha-tocopherol has been on trial—e.g., in the treatment of primary amenorrhoea (Massenbach and Heinsen, 1948, 1949; Massenbach, 1949), cardiovascular disease (Shute *et al.*, 1948a, 1948b), abortion (Vogt-Moller, 1933), and so on.

When it is available in a cheaper form alpha-tocopherol may replace natural oestrogens and stilboestrol in the control of menopausal symptoms, for, even if only 60% of cases respond, the worry of oestrogen-withdrawal bleeding and the (theoretical) risks of genital cell-stimulation are avoided.

Summary

Vitamin E in the form of alpha-tocopherol temporarily relieved severe menopausal flushing in 30 patients (64%) and failed in 17. The dose required is variable, but averaged 18.5 g. over 37 days (£7 per cure).

Failures did not respond to prolonged and heavy doses, but were quickly relieved by stilboestrol.

Of 17 cases followed up after successful treatment 5 remained cured, 12 had further flushings.

Vitamin E is not an aphrodisiac, but dyspareunia may be relieved in time by the healing of senile lesions in the lower genital tract.

Vitamin E produces no sudden change in the clinical appearance of the lower genital tract, although prolonged and heavy dosage seemed to cause healing in 50% of senile vulvar and vaginal lesions.

Vaginal smears seldom alter, and no parallel exists between cell maturation and the cure of symptoms.

The cervix is not stimulated to mucus secretion.

Cell changes were observed in 7 out of 21 urethral smears.

Side-effects were few: one case developed dermatitis; two cases menstruated, one developing a haemorrhagic luteal cyst.

I am grateful to Professor H. N. Lloyd, Professor Dugald Baird, Dr. James Hewitt, and Dr. Carl Crooke for advice in preparing this report. My thanks are also due to Sister M. Scottwell and to Miss M. E. Attwood, who is responsible for the histology and photomicrographs. Messrs. Roche Products, Ltd., Welwyn Garden City, kindly helped us with gifts of ephynal (alpha-tocopherol).

TREATMENT OF DUPUYTREN'S CONTRACTURE WITH VITAMIN E

BY

G. RUSSELL THOMSON, M.B., F.R.C.S., F.R.F.P.S.

(From the Royal Infirmary, Greenock)

Since the preliminary report (Thomson, 1949) on the effect of vitamin E in a case of Dupuytren's contracture further cases have come under review and have yielded promising results. In fact, the general response has been so good that to assert that vitamin E has a specific effect on Dupuytren's contracture does not appear to be unduly reckless. The mode of action is unknown, but the work of Steinberg (1946) on the action of the tocopherols on fibrous tissue renders a relationship a little less mystical.

Reports on the success of this treatment have not been unanimous but are inclined to be in its favour. Steinberg (1946) produced the first paper on this subject and described the effects of massive doses of vitamin E on seven cases of Dupuytren's contracture. In six of these cases the contracture disappeared and the sclerodermatous condition of the skin changed to a normal state. One case failed to respond, and this was attributed to the fact that the patient suffered from early portal cirrhosis. In such cases the blood vitamin E level has been shown to be low and large doses of vitamin E are not absorbed. All these cases were treated with a daily dose of 300 mg. of vitamin E orally over a period of 7 to 53 days. Scott and Scardino (1948) discussed six cases treated with 300 mg. of mixed tocopherols or 200 mg. of "ephynal" daily. One case showed marked improvement, three moderate improvement, and two no change. Wrigley (personal communication, 1949) treated three cases with 400 mg. of "ephynal" a day; there was a definite response in two cases and none in the third.

On the other hand, Langston and Badre (1948) treated five cases with the large doses of vitamin E recommended by Steinberg without any demonstrable result. Parsons (1948) treated one case with 300 mg. a day for over 100 days and reported no objective change, although the patient thought he could open one of his fingers a little more freely. Recently, King (1949) described 13 cases treated with 300 mg. of ephynal a day without result. Four of the cases developed hitherto unreported toxic manifestations, which made further treatment impossible. Four other patients were sure they had gained improvement, but none was seen. The longest period of treatment lasted eight weeks.

Present Series

In this series of 13 cases of Dupuytren's contracture involving 22 hands all cases except one were treated with ephynal, four 50-mg. tablets being the daily dose. The minimum length of time that any case has been under treatment is 12 weeks; the majority have been under treatment for 20 weeks. It was notable that the excepted case above and the one previously reported (Thomson, 1949) were treated with wheat germ oil in a weekly dose of 30 mg. and responded dramatically in two weeks, whereas in the cases treated with ephynal a response was unusual within six weeks and common at about eight weeks.

The initial response was usually subjective in character and the patients variably stated that "the bands feel softer," that "there seems to be a little more movement in the fingers," or that "the pain in the palm has gone." Thereafter improvement clinically started to take place, and progress was steady, with end-results as described below.

The hands were divided into three groups, according to the type and severity of the contracture.

Group A : Early Cases.—In these the disease was of short duration, the palmar bands and nodules were present to a moderate degree, and the fingers were not contracted closer than 90 degrees towards the palm. Ten such hands

FIG. 1.—Case 1 (*a*) before vitamin E; (*b*) after vitamin E.

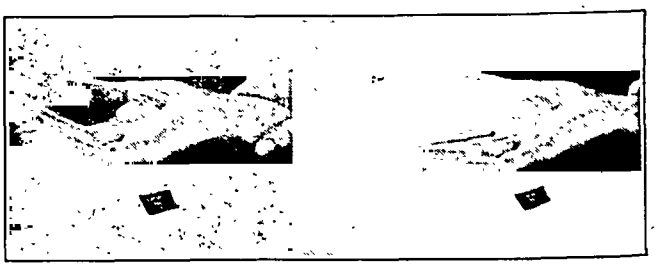

FIG. 2.—Case 3 (*a*) before vitamin E; (*b*) after vitamin E.

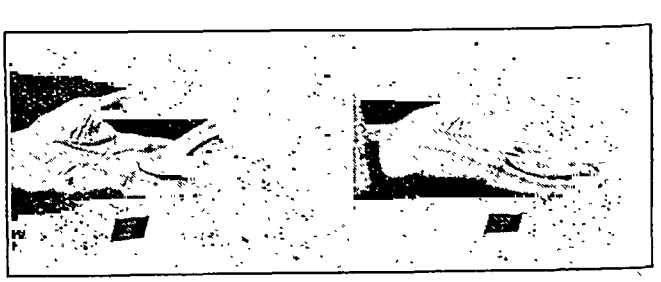

FIG. 3.—Case 6 (*a*) before vitamin E; (*b*) after vitamin E.

were involved. Five responded very well, and full extension of the fingers was restored after the hypertrophied palmar fascia had softened and almost disappeared. Three are still under treatment, and there is every indication that full extension will eventually be obtained in these as well. The remaining two hands had no loss of extension when first seen, and the administration of ephynal has caused some absorption of the palmar masses. The contractures in this group of cases have been so alleviated that additional or alternative surgery has not been considered.

Group B : Late or Chronic Cases.—Here the disease was of long duration, the thickening of the palmar fascia was gross, and the affected fingers were fixed in the palm. All eight cases in this group derived benefit from the administration of ephynal. The palmar masses softened and formed palmar bands running to the appropriate fingers. In addition there was increased movement of the fingers themselves which permitted closer inspection of the palms. The progress was slow, however, and it appeared that a considerable time would have elapsed before an acceptable result could be obtained by the use of ephynal alone. As the palmar bands now invited division, this was carried out in four hands with excellent results. The first hand was treated by simple division of the bands at the bases of the fingers, the medial three being involved. The final result (Fig. 4, c) was only fair so far as full extension was concerned. Nevertheless, the patient was pleased, as he had not used his hand for over two years and has now returned to his former occupation of shifting heavy packing-cases in a store. He has been kept on ephynal until the time of writing, and the sectioned bands have continued to absorb slowly. The other three hands were treated by sectioning the bands in two places—in the palm and at the base of the finger—with better results. Full extension was obtained with all fingers except where joint changes precluded this. The skin deficiency in the palm was made good by skin-grafting, and that at the base of the fingers by Z-plasty or skin-grafting.

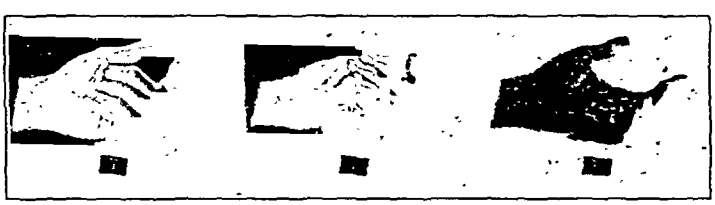

FIG. 4.—Case 7 (*a*) before vitamin E; (*b*) after vitamin E; (*c*) after division of digital bands.

Group C : Old Operated Cases with Recurrence.—Four of these cases were treated with the routine dosage of ephynal. In all, the process of recurrence was halted: in two cases some extension was regained, but in the other two degenerative joint changes and scarred skin have prevented much improvement.

Comment

The results obtained in this series correspond with those reported by Steinberg (1946), with the exception that the rate of response has not been so rapid. This is somewhat offset by the lower dosage of ephynal employed. It is noteworthy that the observers who obtained negative results on the dosage recommended by Steinberg (1946) did not get any objective response after two months' treatment in most cases. However, at the time the treatment was abandoned a number of cases reported symptoms of improvement identical with those recorded in this present series, and it is a matter for speculation that continued treatment might have produced more favourable results.

There was no doubt that the four cases in group B eventually operated on were of a gross type, and surgery alone presented a difficult problem; indeed, two of them had been offered amputation as the only practical method. Steinberg (1947) suggested that in the more chronic cases surgery might be required, with the oral administration of vitamin E in addition. This forecast has been well substantiated with these four cases so treated and already described. This method of treatment has much to commend it when compared with treatment by surgery alone, involving prolonged anaesthesia and wide skin undermining in order to remove adherent masses of palmar fascia.

None of the toxic effects noted by King (1949) were in evidence in this series. Most of the cases have had a routine daily dose of 200 mg. of ephynal for five months or more, and many of these patients have stated in opposition to the above that the drug has had a tonic effect upon them.

The relative merits of the natural wheat-germ oil and the synthetic ephynal have not been investigated, but the lone case treated with the former certainly reacted more quickly.

Although the mode of action of vitamin E in Dupuytren's contracture is not recognized, a specific action is at least suggested by two factors. First, in several cases treated acute pain was experienced in the palmar fascia, and in one case marked swelling and tenderness developed before the contracture began to respond. Secondly, Vogelsang *et al.* (1947), in discussing the effect of vitamin E in heart disease, came to the conclusion that, among other vascular effects, scar tissue was invaded by fresh blood vessels, whereby it became softened and relaxed. That a similar phenomenon may occur in Dupuytren's contracture does not seem outside the bounds of possibility.

I wish to thank Dr. Fred Wrigley for his interest and help with this investigation, and to Roche Products Ltd. for their kindness and generous supply of ephynal.

POLYCYTHAEMIA WITH LEUCOERYTHROBLASTOSIS

BY

F. GRAHAM MARSON, M.B., M.R.C.P.
Senior Medical Registrar, General Hospital, Birmingham

AND

M. J. MEYNELL, M.D., B.Sc., D.P.H., M.R.C.P.
Clinical Pathologist, General Hospital, Birmingham

Few cases of leucoerythroblastic anaemia following on polycythaemia have been described in this country (Stone and Woodman, 1938; Vaughan and Harrison, 1939). The term "leucoerythroblastic anaemia," or, better, leucoerythroblastosis (as there may be no anaemia), is used to describe a condition characterized by the presence of immature red and white cells in the peripheral blood, and is due to or associated with replacement of the bone marrow by some other tissue. It is usually classified as follows.

Primary.—(*a*) *Infantile:* osteosclerosis fragilis generalisata (marble bones). This is congenital and may be familial.

(*b*) *Adult:* osteosclerosis; myelofibrosis; agnogenic myeloid metaplasia; and aleukaemic megakaryocytic myelosis. In all probability these last are different names for or different aspects of the same condition. If it were possible to examine a large enough sample of bone marrow during life it might be found that fibrosis and osteosclerosis, pronounced myeloid and erythroid activity, and megakaryocytic excess were all occurring coincidently at different sites. Splenomegaly and, less often, lymphadenopathy may be present.

Secondary or Symptomatic.—Carcinomatosis of bone; multiple myelomatosis; Hodgkin's disease; and lipoidoses. The anaemia may be normocytic or macrocytic. The white cell count may be high or low. The immature cells, the presence of which is an essential part of the disease, are said to be derived from the heterotopic foci in the spleen, liver, kidney, etc. These tissues, it is stated, are incapable of retaining the cells until complete maturation results. Thrombocytopenia may be present. The splenomegaly is due to myeloid metaplasia, although infarcts may add to the enlargement.

Radiographic changes characteristic of the disease have been described—i.e., irregular increased density of the spongiosa of long bones and throughout the flat bones, as well as decreased density of the cortex of long bones (Vaughan and Harrison, 1939). The interpretation of these radiographs requires some experience, and must be compared with controls of the same age and sex. The trephine biopsy will in many cases confirm the diagnosis.

The object of this paper is to record two further cases of leucoerythroblastosis, both of which presented with polycythaemia. The two patients are alive at the time of writing.

Case 1

A married woman with two children first attended hospital in May, 1936, at the age of 32, with a history of having noticed a lump in the left subcostal region one year previously. It had gradually increased in size and had been accompanied by pain on exertion during the previous five months. The only other illness was migraine for 20 years. Examination showed her to be of slim build, cyanosed, with the spleen enlarged to the umbilicus, and the liver enlarged two fingerbreadths below the costal margin. Blood pressure 120/90; van den Bergh indirect reaction faintly positive. A blood count confirmed polycythaemia (see Table I).

July, 1936.—Admitted to hospital; polycythaemia persisted; fractional test meal showed low-acid curve; red-cell fragility test revealed a commencing haemolysis in 0.55% saline, complete in 0.3%; occasional nucleated red cells seen. Course of deep *x*-ray therapy to spleen and lumbar spine.

April, 1937.—No serious symptoms; spleen smaller; haemoglobin 116%.

October, 1937.—Better; haemoglobin 108%.

May, 1938.—No symptoms; haemoglobin 98%.

May, 1939.—Following deep *x*-ray therapy, had amenorrhoea for two years, since when menstruation has been heavy and irregular. Pale; haemoglobin 84%. Seen by Sir Beckwith Whitehouse, who thought *x*-ray therapy may have produced defective luteinization, and recommended progesterone therapy.

July, 1940.—Slight continual uterine haemorrhage for three months; haemoglobin 92%, with a few nucleated red cells present; referred to gynaecology department, where no pelvic cause of bleeding was found.

October, 1942.—Recent pain over splenic area, worse on exertion. On examination: spare, healthy-looking; spleen enlarged to left iliac fossa; liver and glands not enlarged; blood pressure 130/70; leucoerythroblastic anaemia present.

July, 1945.—Health fairly good since October, 1942, but has noticed progressive enlargement of the spleen.

April, 1946.—Admitted to hospital with further aching pain in left flank; amenorrhoea for three years. Spleen enlarged to left iliac fossa and tender on bimanual examination; blood

pressure 160/90. Radiographs of bones of forearms show osteoporosis; serum calcium 8.6 mg. per 100 ml.; serum phosphorus 3.6 mg. per 100 ml. Leucoerythroblastic anaemia present. Surgical belt supplied to support huge spleen.

June, 1948.—Admitted to hospital. *Exacerbation of severe continual* pain over spleen for one month, made worse by movement or deep breathing. Pale; spleen enlarged to both iliac fossae and very tender on palpation; leucoerythroblastic anaemia present. Platelets 238,000; reticulocytes 2.4%; radiograph of long bones showed osteoporotic appearance of upper half left humerus; sternal-marrow puncture gave a picture not unlike that present in the peripheral blood. A diagnosis of myelofibrosis was made clinically, and sternal biopsy was performed with a view to confirming this, since radiographs of long bones were indefinite. The biopsy was reported on as follows: "These small fragments of sternal tissue show diffuse fibrotic changes with occasional isolated megakaryocytes—very suggestive, if this is representative, of myelofibrosis."

Case 2

A married woman aged 64 first attended hospital in 1924, complaining of pain in the splenic region; a diagnosis of polycythaemia vera was made and *x*-ray therapy given. Attended regularly for eight years and was free from symptoms until 1942. No records available up to this date.

August, 1942.—Pain in splenic region for two months; spleen enlarged to umbilicus and tender; blood pressure 155/90. Red blood cells 4,700,000: normoblasts present (see Table II).

It was considered that this indicated the development of either myelosclerosis or aleukaemic leukaemia. Sternal puncture was twice performed and the picture was essentially that of the peripheral blood; the bone seemed soft and gritty on puncture. These findings are typical of myelofibrosis. Bleeding time 5½ minutes; clotting time 4½ minutes; prothrombin 55% of normal. Serum proteins 6.52 g.%; serum uric acid 5.6 g.%; serum alkaline phosphatase 7 units; blood urea 27 mg. per 100 ml. A barium swallow radiograph showed some irregularity of oesophageal wall consistent with varices; radiographs of sternum and femora were normal.

On June 17, 1948, the patient left hospital against advice. The diagnosis was considered to be myelofibrosis following polycythaemia vera, with cirrhosis of liver.

Comment on the Cases

Case 1 presented as a case of polycythaemia rubra vera and was treated with deep *x* rays. The blood count gradually fell, and once below normal never rose again. This suggests that the case was one of primary myelofibrosis presenting as polycythaemia (see Vaughan and Harrison, 1939). It is of course possible that the patient had previously had polycythaemia rubra vera and had already developed myelofibrosis when first seen. Certainly, in June, 1948, the sternal biopsy demonstrated myelofibrosis The corpuscular fragility was increased (admittedly slight), which coincides with the findings of Vaughan and Harrison

TABLE II.—*Case 2. Blood Counts*

Date	R.B.C. (Thousands per c.mm.)	Hb %	W.B.C. (per c.mm.)	Varieties of Leucocytes %									Platelets (per c.mm.)	Remarks

April, 1944.—Slight ache over spleen for three weeks. Red blood cells 4,465,000.

September, 1944.—Patient noticed increasing size of left side of abdomen, but otherwise felt fairly fit; spleen enlarged as far as left iliac fossa; liver enlarged below umbilicus; red blood cells 7,970,000. Admitted to hospital and further course of deep *x*-ray therapy given to spleen, followed by phenylhydrazine therapy. Further *x*-ray therapy given in May, 1945.

June, 1946.—Blood count satisfactory, but in December, 1946, again markedly polycythaemic. Further deep *x*-ray and phenylhydrazine therapy given.

October, 1947.—Purpura on legs and arms; platelet count 270,000 per c.mm.; blood count satisfactory except for numerous unsegmented polymorphs.

May, 1948.—Admitted to hospital with eight weeks' history of lassitude, swelling of ankles, and noticeable enlargement of abdomen; rubicund facies; few petechiae of limbs; abdomen distended, with everted umbilicus and shifting dullness; spleen enlarged to right iliac fossa; blood pressure 145/95. Blood count showed mild hypochromic anaemia with numerous immature leucocytes, a few normoblasts, and 54,000 platelets per c.mm.

Case 2 was diagnosed as a case of polycythaemia rubra vera. From 1924 until 1947 this patient had a typical polycythaemic count. In May, 1948, she showed many of the features of leucoerythroblastosis associated with myelofibrosis—i.e., leucopenia, presence of immature red and white cells in the peripheral blood, gross splenomegaly, and a presumably non-functioning bone marrow. Myelofibrosis was suspected on the grounds that sternal puncture revealed a soft gritty bone, and the material, when examined, showed a picture not unlike that found in the peripheral blood. Such a terminal event in polycythaemia rubra vera has been recorded.

Discussion

The pathogenesis of the primary variety is obscure Vaughan (1934) suggested that the undifferentiated mesenchyme develops predominantly along one line to produce fibroblasts or osteoblasts. There is no attempt to explain why this should happen. Myelofibrosis and osteosclerosis have followed benzol and phosphorus poisoning. The

picture of osteosclerosis with leucoerythroblastosis can occur in fluorosis. *X* rays have been known to produce fibrosis of the marrow; and Joan Ross (1932) describes the effects of gamma radiation over a period of three years. The marrow showed hyperactivity of the myeloid and erythroid cells with a marked increase in megakaryocytes. The nutrient vessels showed endothelial thickening and intravascular thrombi. It is not beyond possibility that repeated doses of deep *x* rays over many years may produce the picture of myelofibrosis in polycythaemia rubra vera.

Thanks are due to Professor A. P. Thomson and Dr. O. Brenner for permission to publish these cases; and to Dr. J. L. Stafford for his report on the sternal biopsy.

A CASE OF WEIL'S DISEASE, WITH TESTS FOR LIVER FUNCTION

BY

F. E. de W. CAYLEY, M.D., M.R.C.P.
Senior Registrar, St. Stephen's Hospital, Chelsea

Familiarity with Weil's disease during the war has resulted in several publications in the English and American literature. Although jaundice is usually a marked feature of this disease, there is no record of liver-function tests. The following case is therefore described, together with the result of tests for liver dysfunction and for other biochemical disturbances. These were of great help in excluding the diagnosis of acute hepatic necrosis, which was made on admission. It is hoped that this will stimulate physicians who have greater opportunities for studying this disease to investigate its chemical pathology, and to deduce from their findings evidence concerning the site of tissue damage.

Case Report

The patient, a plumber aged 58, was admitted on April 13, 1949. Up to a week previously he had been working on a boiler in a meat-pie factory in which fat was rendered down. Seven days before admission he had a rigor; this was followed by another two hours afterwards. Four days later he noticed he was yellow, and he began to vomit incessantly. There was no abdominal pain.

On examination he was a very ill man, dehydrated, with subsultus tendinum, deep jaundice, and a generalized purpuric eruption. The mucosae were pale. He was afebrile; the pulse rate was 90, the blood pressure was 130/80, the heart sounds were faint, and there were basal crepitations. The liver was not palpable. There was some free fluid in his abdomen, and his stools were pale. Three days later he developed a swinging temperature up to 102° F. (38.9° C.), which was maintained for five weeks and subsided by lysis, and which did not respond to penicillin, 250,000 units six-hourly intramuscularly for 10 days.

He was given 5 pints (2.34 litres) of fluid by mouth, 3 pints (1.7 litres) of "casydrol" by intravenous drip transfusion, 6 ml. of "campolon" intramuscularly, 500 mg. of ascorbic acid, and 15 mg. of vitamin K daily. Later he developed a urinary infection with *Pseudomonas pyocyanea*, for which he was given 4 g. of streptomycin daily by injection for five days.

Subsequent Course.—His rash cleared up in three days; the jaundice had faded by the first week in July, but he was pyrexial for a month. However, he remained mentally in a state of stupor, with considerable clouding of consciousness, marked loss of memory for recent events, and disorientation in time and place. Some measure of recovery occurred, but when his wife took him on May 31 he was able to sit out in a chair, though he showed a good deal of mental deterioration, with lack of all initiative and poor memory. A letter from his wife on July 27 stated that his general condition had improved, but his legs were weak and useless and his mental state poor.

Investigations

Agglutinations.—*L. icterohaemorrhagiae:* April 20, 1:1,000; April 29, 1:1,000; May 5, 1:3,000. *L. canicola, nil. Salm. typhi, Salm. paratyphi* A, *Salm. paratyphi* B, and *Br. abortus, nil.*

Blood Counts.—Haemoglobin: April 14, 59%; May 9, 59%; May 23, 72%. Red cells: April 14, 3,750,000; May 9, 3,020,000; May 23, 3,500,000. White cells: April 14, 25,000 (P. 77%, L. 21%, M. 1%); May 9, 25,000 (P. 89%, L. 10%, M. 1%); May 23, 18,000 (P. 75%, L. 25%, M. 4%).

Serum Proteins.—April 24: total, 5.75 g.% (albumin 4.2, globulin 1.5; A/G ratio 2.7:1). May 5: total, 5.5 g.% (albumin 3.7, globulin 1.8; A/G ratio 2.05:1).

Liver-function Tests.—Alkaline phosphatase: April 24, 10.7 units; May 5, 16.3 units; May 23, 12.8 units. Thymol turbidity: April 24, 1.5 units; May 5 and 23, 1 unit. The Takata-Ara and colloidal gold tests were negative.

Urine.—April 19 and 25: specific gravity, 1010; albumin, sugar, and bile salts, *nil*; bilirubin was in excess on April 19 and urobilin was present on April 25. On April 25 there were 10 cells per field and *Ps. pyocyanea* was found. On May 30 there were many pus cells and *Ps. pyocyanea* was still present. There were no spirochaetes.

Haemolysins.—On May 30 no cold agglutinins were present, and Coombs's direct and indirect tests were negative.

On April 14 the serum diastase amounted to 320 mg. per 100 ml. (normal, 70–150 mg.). On April 22 the blood urea was 27 mg. per 100 ml., the alkali reserve 49 volumes, and the serum calcium 8.6 mg. per 100 ml. On May 10 the blood urea was 35 mg. per 100 ml. and the alkali reserve 43.9 volumes. On April 22 the blood sugar totalled 148 mg. per 100 ml., and the serum cholesterol 177 mg. per 100 ml. (free, 80 mg.; ester 97 mg.).

The diagnosis was based on the presence of jaundice, the rash, the patient's occupation, and the rising titre of agglutinins.

Comment

The morbid pathology of the liver in Weil's disease is described by Hutchinson *et al.* (1946). They say that the liver in their cases was usually of normal size, with masses of bile pigment in the biliary canaliculi of the centrilobar part of the liver lobules, and emphasize the absence of necrosis. On the other hand, Heringman and Phillips (1947) mention considerable disorganization of the liver pattern with moderate vacuolization and swelling of cells and the formation of continuous cords of liver cells instead of normal groups of two or three cells.

In the case described by Jackson and Oleesky (1946) there was no macroscopic hepatic necrosis; there were scattered areas of fatty degeneration and areas of regeneration, with enlarged binucleated liver cells. They mention that Walch-Sorgdrager (1939) refers to the frequent misdiagnosis of acute yellow atrophy, as happened in our case.

Our case on admission, being afebrile at the time and extremely ill and toxic, closely resembled the picture of acute hepatic necrosis. The finding of normal plasma proteins and Takata-Ara, thymol turbidity, and colloidal gold tests was therefore of distinct value in excluding this diagnosis, and would seem to rule out any overwhelming degree of parenchymal damage.

The absence of urobilin in the urine in the early stages would seem to point to an obstructive element in the jaundice such as might be caused by the bile pigment masses in the small canaliculi that Hutchinson *et al.* described; however, the alkaline phosphatase was never above 16.3 units. Unfortunately the Coombs tests were done too late to exclude a haemolytic factor. Apart from the complicating *Ps. pyocyanea* infection there was no evidence of renal damage. The blood urea remained normal, and there were no casts or red cells in the urine. The serum diastase value of 320 mg. per 100 ml. would appear to suggest disturbance of pancreatic function.

The mental state of the patient is worthy of passing comment. There was never any sign of meningitis leptospirosa. Three possible theories about causation are: first, that the condition was due to cerebral damage by the organism or its toxins; secondly, that it was due to the severe jaundice; and, thirdly, that the haemorrhagic state present at the onset in the skin was also present in the brain; this is, I think, the most likely.

Summary

A case of Weil's disease, with liver-function tests, is described.

An attempt is made to correlate these with previously described accounts of the pathology of this condition.

Other interesting features of the case are briefly dwelt on.

My thanks are due to Dr. A. G. Signy and the staff of the laboratories of St. Mary Abbots Hospital and the Archway Hospital for the pathological reports.

PRIMARY LYMPHOSARCOMA OF APPENDIX OCCURRING IN CHILDHOOD

BY

J. H. GALLOWAY, M.B., Ch.B., M.R.C.P.Ed., D.C.H.

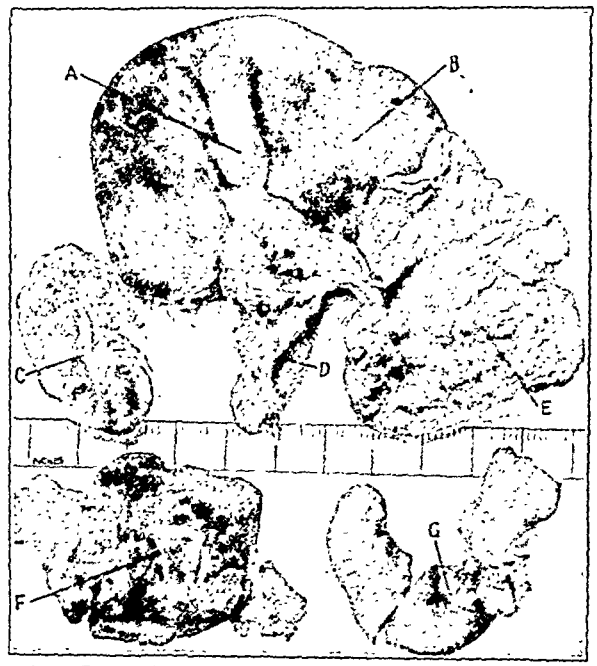
Late Medical Registrar and Tutor, Department of Child Health, University of Liverpool

AND

E. J. OWENS, M.B., Ch.B., L.M., D.C.H.

Late Senior Resident Medical Officer, Alder Hey Children's Hospital

Lymphosarcoma arising in the appendix is rare; only seven cases occurring in childhood have been published. In a majority of such cases the children have had symptoms suggestive of appendicular disease. In the following case the patient had no such symptoms, and the clinical picture which presented was therefore of special interest.



Case Report

A boy aged 6 years 9 months was admitted to hospital on October 1, 1948. The child had been well until four weeks before admission, when he was immunized against diphtheria. Since then he had been "off colour" but had attended school. Three days before admission he complained of pain in his chest and right thigh, and vomited once. His mother noticed a swelling on his left temple on the following day; but there had not been any loss of weight or other symptoms. There was nothing relevant in the family history or in the child's previous personal history.

On examination his temperature was 100° F. (37.8° C.), pulse 80, and respirations 20. The child's general condition was poor; he was very irritable and complained of pains in all his joints. A swelling on the left temple was noted and there were palpable glands in the left axillary and cervical regions. Abdominal examination revealed tenderness in both iliac fossae, but there were no palpable masses. Routine clinical examination did not show any further abnormal features.

For the first three days the temperature varied between 98.4 and 102° F. (36.9 and 38.9° C.). On the fourth day his temperature fell and remained normal until the eighth day, when it rose to 103° F. (39.4° C.). At this time the left knee-joint was slightly swollen. There was no cardiac enlargement, but a soft apical systolic murmur could be heard. The abdomen was rather large and doughy, with dullness in both flanks. The liver was enlarged one fingerbreadth below the costal margin and the tip of the spleen was felt. The kidneys were not palpable and no other abdominal masses were found. There were no abnormal signs in the central nervous system.

Radiographs of the chest, abdomen, and skull, a Mantoux test (1:10,000 dilution), blood culture, and Widal reactions

A = Gall Bladder; B = Liver; C = Kidney; D = Pancreas; E = Stomach; F = Ileal Mass; G = Appendix.

were all negative. The erythrocyte sedimentation rate was 50 mm. in one hour. The blood picture was: haemoglobin, 68%; red cells, 3,920,000; white cells 5,000 (polymorphs 54%, myelocytes 7%, metamyelocytes 14%, lymphocytes 20%, monocytes 3%, eosinophils 2%). An intravenous pyelogram, the blood Wassermann reaction, and a blood-urea estimation were all negative. No Bence-Jones proteose was present in the urine, and the stools did not contain either visible or occult blood.

The pyrexia was maintained despite penicillin and salicylate therapy. The liver increased in size to two fingerbreadths below the costal margin. The swelling over the left temple had increased in size and was now 1 in. (2.5 cm.) in diameter; it was tender and gave the impression of deep fluctuation. No further lymphatic gland enlargement developed. The child's appetite remained good, but despite this he was obviously becoming more wasted. His bowels were normal and he had no vomiting. An irregular soft mass, thought to be faeces, was felt in the right iliac fossa on the thirteenth day. The rectum was found to be loaded with soft brown faeces, but there was no palpable mass. Just below the ninth costal cartilage a small nodule was felt on the enlarged liver. There were no signs

of free fluid in the peritoneal cavity. The abdominal girth was 21¼ in. (54 cm.). The blood pressure was 130/70 mm. Hg.

The abdominal mass became progressively larger and firmer, but signs of obstruction were not observed. His pallor increased, and despite a blood transfusion he died 32 days after admission. Before he died the child developed proptosis of the left eye and a left-sided facial weakness.

Post-mortem Findings

The appendix measured 12 cm. in length and 4 cm. in diameter. It was horn-shaped, with a smooth white serosal surface (see Fig.). On section it consisted throughout of a uniform white homogeneous tissue in which the lumen could not be distinguished. This condition ceased abruptly at the root of the appendix. There were widespread deposits of a similar tissue throughout the body, affecting practically every organ.

Histology.—The greatly enlarged appendix consisted of sheets of cells resembling small lymphocytes which obliterated the lumen and destroyed muscle, leaving only traces of widely separated muscle fibres in the external layer. Occasional mitoses were to be seen. Silver staining showed very scanty reticulin fibres traversing the tissue, particularly in relation to small vessels: large tracts of cells were devoid of reticulin. The other structures containing obvious tumour showed similar histological changes. The spleen, pancreas, and thyroid, although normal to naked-eye examination, showed a slighter degree of infiltration.

Discussion

Knox (1945) gave details of a boy aged 4 years with lymphosarcoma arising in the appendix, and he reviewed 16 cases of undisputed primary lymphosarcoma of the appendix, of which five had occurred in childhood (Warren, 1898; Rohdenburg, 1919; Friend, 1926; Capecchi, 1927; Apitz, 1933). A further search of the literature revealed one other case in childhood (Carnelli, 1931). So far as can be ascertained no such case occurring in childhood has been reported in British literature.

In all reported cases, except that of Apitz, the presenting symptoms were suggestive of acute or subacute appendicitis. Laparotomy was performed and a tumour involving the appendix found and removed. The age, sex, presenting symptoms, duration, nature of operation and findings, and period of follow-up are shown in the accompanying Table.

In our case the uniform homogeneous appearance of the appendicular lesion, with complete replacement of the inner layers of the wall of the appendix by lymphosarcomatous tissue, suggests that the disease arose there, and is in contrast with another large mass in the ileum, which seems to have been formed by the fusion of several submucous lesions similar to those seen elsewhere in the intestinal wall.

Lymphosarcoma occurs more commonly in males, and in the reported cases the ratio of males to females was 3 to 1. Munson and Mann (Guthrie, 1948) believe that the outlook is good after surgical removal of a solitary tumour. Knox (1945) suggests that radiotherapy may be expected to be helpful in prolonging life and may even cure if the disease is localized. Sugarbaker and Craven (1940) state: "The occasion of a primary site in the gastro-intestinal tract regardless of sporadic reports of cures seems to carry an unfortunate outlook. None of the patients whose stomach or small intestines were involved lived for five years, the average survival period being 6.6 months."

Table Showing Details of Reported Cases

Reported By	Age in Years	Sex	Presenting Symptoms	Duration	Operation	Follow-up	Operation Findings
Apitz (1933)	8	Male	Died from uraemia	Approx. 6 weeks	None	None	Appendix 5 cm. in circumference and 17 cm. in length
Capecchi .. (1927)	8	..	Mild abdominal pain in right lower quadrant	1 month	Appendicectomy	None	Distal third of appendix tumour size of hen's egg
Carnelli .. (1931)	10	..	Pain in right lower quadrant	2 months	Appendicectomy, excision of left part of caecal wall	Asymptomatic 14 months later	Appendix with tumour at proximal end 2·5 cm. long by 0·5 cm. broad: the caecal wall was infiltrated
Friend (1926)	9	Female	Recurrent cramp-like abdominal pain in right lower quadrant	3–4 weeks	Appendicectomy (high unrotated caecum)	Death 1 month later	Hard, firm, thick appendix 15 cm. long
Knox (1945)	4	Male	Intermittent pain right lower quadrant with nausea, vomiting, and moderate diarrhoea	2 months	Appendicectomy	Asymptomatic 15 months later	Appendix 9·5 cm. long, 18 mm thick
Rohdenburg (1919, 1921)	4	Not given	History suggestive of acute appendicitis with pre-operative diagnosis of intussusception	No time stated, but apparently acute	Appendicectomy with partial removal of caecum	No recurrence after 10 months	New growth involving proximal third of appendix and extending into caecal wall
Warren .. (1898)	6	Male	Intermittent pyrexia and pain in right lower quadrant	1 month	Resection of part of ileum, caecum, and appendix	None	Appendix size of thumb
Present case	6½	..	Pyrexia and vague ill-health. No symptoms referable to abdomen	1 month	None	None	Appendix 12 cm. long by 4 cm. broad

We should like to thank Professor N. B. Capon for his help and advice; Dr. W. E. Crosbie, medical superintendent, Alder Hey Children's Hospital, Liverpool, for permission to publish this case; and Dr. E. G. Hall for the pathological reports.

The National Insurance Advisory Committee has been asked to consider and report on preliminary draft regulations concerning students from outside the United Kingdom who during a vacation become temporarily employed in Great Britain. The effect of the regulations is that, in cases approved by the Minister of National Insurance, contributions under the National Insurance scheme will not be required unless the students are continuously resident in Great Britain for 26 weeks. Industrial injuries contributions remain payable. Copies of the preliminary draft of these regulations (the National Insurance (Residence and Persons Abroad) Amendment Regulations, 1950) can be bought for 1d. from H.M. Stationery Office or any bookseller. The committee will consider written objections to them if sent before January 3, 1950, to the Secretary, National Insurance Advisory Committee, 6, Curzon Street, London, W.1.

SURGICAL MANAGEMENT OF THE AGED

A SURVEY OF RESULTS OF MAJOR SURGERY IN 99 PATIENTS OVER 70

BY

PETER CHILDS, D.M., M.Ch., F.R.C.S.

Surgeon, South Devon and East Cornwall Hospital, Plymouth. Late Surgical First Assistant, King's College Hospital

AND

STANLEY A. MASON, M.B., B.S., D.A.

Assistant Anaesthetist, King's College Hospital

"The days of our years are threescore years and ten; and if by reason of strength they be fourscore years, yet is their strength labour and sorrow; for it is soon cut off, and we fly away."

The average age of the population is increasing, and is likely to do so. It therefore seems reasonable to survey the results of surgery in those patients who are over the age of 70 years, the one-time allotted span of life.

During the thirty months January, 1947, to June, 1949, 1,609 patients were admitted to the 32 surgical beds of one surgical unit at a London teaching hospital. Of these 1,609 patients 131 were over the age of 70—seven were not submitted to surgery, 24 were submitted to minor surgery, and 99 were submitted to major surgery. It is instructive to compare this situation with those existing 10 and 20 years ago. Table I shows in a comparable number of admissions the numbers of patients over 70 seen and the number of these patients submitted to major surgery. Applying the rules of significance to these figures, it will be apparent that more patients over the age of 70 were admitted in 1947–9 than was the case 20 years ago, and that more patients over the age of 70 were submitted to major surgery than was the case 10 years ago.

TABLE I

Period	Total Admitted	No. Over 70	No. of Patients Over 70 Submitted to Major Surgery
Jan., 1927, to Nov., 1929	1,609	82 (5·1%)	40 (49%)
Jan., 1937, to Sept., 1939	1,609	108 (6·7%)	61 (56%)
Jan., 1947, to June, 1949	1,609	131 (8·1%)	99 (75%)

It is the 99 patients in our series submitted to major surgery that we wish to discuss. Distribution between the sexes was almost equal—49 males and 50 females. Fifteen patients were admitted as emergencies; 17 patients (6 females and 11 males) died before discharge from hospital

Operations Performed

Operations on the Head and Neck

Section of sensory root, fifth cranial nerve	1
Hemiglossectomy	2
Block dissection glands of neck	1
Section thyroglossal cyst	1
Subtotal thyroidectomy	1
Excision of large rodent ulcer of nose and skin graft	5

Operations on the Trunk and Upper Limbs

Radical mastectomy	1
Lymphangioplasty	4

Hernias and the Scrotum

Incisional hernia	2
Inguinal hernia without strangulation	1
Strangulated inguinal hernia repair	8
Strangulated inguinal hernia with resection	1
Femoral hernia repair	2
Strangulated femoral hernia, resection, and anastomosis	2
Operations on scrotum and contents	2
Incarcerated umbilical hernia	7

Intra-abdominal Operations

Colostomy	4
Closure of colostomy	10
Laparotomy	5
Laparotomy and colostomy	1
Laparotomy, colostomy, repair of inguinal hernia, and dorsal slit	1
Laparotomy and cholecystenterostomy	1
Laparotomy and suprapubic cystostomy	1
Cholecystostomy	1
Cholecystectomy	1
Cholecystectomy and choledochotomy	1
Suture of perforated peptic ulcer	3
Gastrotomy	1
Gastrostomy	2
Subtotal gastrectomy	1
Subtotal gastrectomy and colectomy	1
Gastro-enterostomy	1
Transabdominal repair of diaphragmatic hernia	1
Transthoracic oesophago-gastrostomy	2
Appendicectomy	2
Caecostomy	1
Right hemicolectomy	1
Ileo-transverse-colostomy	1
Resection sigmoid colon	1
Resection sigmoid colon and colostomy	7
Perineal excision of rectum	3
Perineal excision of rectum and colostomy	1
Abdomino-perineal excision of rectum	
Perineo-abdomino excision of rectum	
Excision of ovarian cyst	2

Operations on Prostate and Anal Canal

Haemorrhoidectomy	2
Prostatectomy	5
Transurethral resection of prostate	8

Operations on the Lower Limbs

Above-knee amputations	1
Below-knee amputations	2
Manipulations of ankle	1
Excision of popliteal aneurysm	

A number of these patients underwent minor surgical procedures requiring further anaesthetics.

Preparation of the Patient for Operation

A full clinical examination was made, with special reference to the heart and lungs. After the age of 70 it is only natural to find signs of wear and tear in the cardio-vascular and respiratory systems. Of these 99 cases 60 showed clinical evidence of abnormalities in one or both of these systems:

Gross hypertension (i.e., B.P. 180/100 or more)	14
Hypertension or signs of myocardial insufficiency	13
Signs of myocardial insufficiency	6
Hypertension and/or myocardial insufficiency and signs and symptoms of respiratory disease	15
Respiratory disease alone	12

In addition, arteriosclerosis, anaemia, and wasting were very common findings.

Operation was delayed in 13 cases; the reasons for delay were:

Patient in bed too long	1
Poor nutrition	2
Dehydration	1
Dehydration associated with low percentage of haemoglobin	1
Low percentage of haemoglobin	2
Abdominal distension	2
Respiratory disease	4

Pre-operative Measures Taken.—The usual treatment for shock was practised according to the severity. Throughout this series of cases it has been customary to encourage

early rising after operation. Therefore, when a patient had been confined to bed for a period, operation was delayed while he was made ambulant so that he could be sat out of bed immediately after recovery from the anaesthetic. If possible, general nutrition was improved. In some cases it was necessary, as in a case of achalasia of the cardia, to give a high-calorie diet through an oesophageal tube. Vitamin intake was maintained when necessary by intramuscular injection of vitamin C and "heparglandol B," and "synkavite" was given as a routine in all cases undergoing surgery of the biliary system. Dehydration was corrected by intravenous saline or glucose-saline; blood transfusion was given pre-operatively in all cases which showed a low haemoglobin percentage. Distension increases the risk of operation and also the difficulty. Where the operation was not in itself likely to be a decompressing procedure, operation was delayed if distension was present while a Miller-Abbott tube was passed. A Ryle's tube was passed on all patients who were vomiting pre-operatively. All cases with respiratory disease and all cases about to undergo intra-abdominal operations were given pre-operative breathing exercises unless the case was an emergency. Coughing and postural drainage were encouraged in those who had productive coughs; penicillin inhalations were given and systemic penicillin and sulphonamides started. In some cases this treatment was carried out for one week before operation. Digitalis therapy was given to those with auricular fibrillation.

Premedication.—All cases received a hypodermic injection of 1/100 gr. (0.65 mg.) of atropine half an hour before operation. In addition, those with marked pain received 1/6 gr. (11 mg.) of morphine. Hyoscine (scopolamine) was purposely avoided because of its tendency to produce disorientation and restlessness in the aged, and morphine was avoided or kept to a minimum in order not to depress the vital capacity.

Anaesthesia

The choice of anaesthetic was determined to a large extent by the type of operation to be performed and the general condition of the patient. Of the 134 anaesthesias, 81 were for intra-abdominal and 53 for extra-abdominal procedures. The agents used for the various types of operation are shown in Table II.

TABLE II.—*Anaesthetic Used*

	Intra-abdominal (Including Intrathoracic)	Extra-abdominal (Including Intracranial)	Total
Curare and light anaesthesia	52	3	55
Spinal and local	10 (7 spinal, 3 local)	1 (spinal)	11
gas, oxygen, ether, oxygen, ether and cyclopropane	16	16	32
	3	7	10
Thiopentone, gas, oxygen, and trilene	—	20	20
Bromethol, gas, oxygen, and trilene	—	2	2
Thiopentone	—	4	4
Total	81	53	134

Thiopentone.—When thiopentone was used for induction it was injected very slowly, because the circulation time in the aged is prolonged. Also, owing to the low basal metabolic rate in the elderly, the elimination of thiopentone in the body is slower, and liver and kidney damage may be present. Hence only very small doses were used—rarely more than 0.5 g.

Curare.—Curare in the form of *d*-tubocurarine chloride was mostly used when relaxation was required. The initial dose was usually 10 mg., and the final total dosage depended on the agent used to maintain light anaesthesia; with ether, approximately half the usual dosage of curare is required. The closed-circuit carbon-dioxide-absorption technique was used as a routine for cases receiving curare; the basal oxygen requirement in the aged is low, but at the same time suboxygenation must be avoided. This often entailed assisted respiration for the whole of the operation, as some degree of stagnant hypoxia was already present owing to a poor myocardium and a sluggish peripheral circulation

Spinal Analgesia.—This method was used only if the site of operation was subumbilical, if the patient's blood pressure was within normal limits, and if the condition of the chest did not warrant an inhalational method.

Local Analgesia.—This method was used in three cases: in an emergency laparotomy with faecal vomiting, in an emergency caecostomy in a patient who was in cardiac failure, and in a patient with incarcerated incisional hernia who was in early cardiac failure.

Intubation.—Intubation of the trachea was carried out in all abdominal cases. If vomiting was a pronounced symptom, as in cases with bowel obstruction, intubation was performed with a cuffed intratracheal tube, and a sucker was at hand to keep vomitus clear of the larynx The Ryle's tube was kept in place throughout the operation and aspirated from time to time.

Position on the Operating Table.—Old people are prone to osteoarthritis, and their skins withstand pressure badly For these reasons their position on the operating table must be carefully supervised, a support provided for the back, shoulder-pieces well padded, and hands not placed under the buttocks.

Resuscitative Measures.—Patients suffering from pre-operative shock or dehydration continued with blood or saline throughout the operation. If a long operation was anticipated a slow blood drip was started at the beginning of the procedure. If signs of shock developed during an operation blood or plasma was administered. All such cases returned from the theatre to the ward with their intravenous drips still running.

Post-operative Measures

As soon as the patient was sufficiently recovered from the anaesthetic, he or she was sat up and encouraged to cough, to take deep breaths, and to move the legs. The services of a trained physiotherapist were found to be invaluable in this respect. Five-minute inhalations of carbogen every hour were a useful adjunct to physiotherapy. The patient was sat up in a chair within 12 hours of operation in all cases in which it was practicable. Where the likelihood of respiratory complication was great, even patients undergoing gastric suction and intravenous drip therapy were so treated. They sat in a chair for increasing periods each day from then on. Continuous gastric suction and intravenous therapy were practised for 48 hours after operation in all cases undergoing an intra-abdominal operation which might result in paralytic ileus. Intravenous therapy and suction were stopped only when intestinal movements were well established. Watch was kept over the bladder to ensure that retention with overflow did not occur. The usual measures to combat retention were practised up to 24 hours, after which catheterization was performed if necessary. Where retention was persistent and due to prostatic hypertrophy, an indwelling catheter was used until the patient was considered fit for a transurethral resection, and penicillin or a sulphonamide was administered. Routine testing of urine for chlorides was practised from the first post-operative day.

Post-operative Therapy.—All drugs administered pre-operatively were continued in the post-operative period—i.e., penicillin, sulphonamides, or digitalis. In all major abdominal procedures, and where sepsis was a danger, prophylactic penicillin and sulphonamides were administered. Where cardiovascular complications occurred digitalization was instituted. In all cases of respiratory complications and in those cases in which coughing was difficult owing to tenacious sputum, mistura sodii chloridi composita (*N.W.F.*) was found to be invaluable.

(*e*) *Retention of Urine.*—Four cases of retention of urine required transurethral resection of the prostate.

(*f*) *Pressure Sores.*—These occurred in three cases.

(*g*) *Cardiovascular System.*—Auricular fibrillation (electrocardiogram showed poor myocardium in one case), 3; auricular flutter, 1; incipient cardiac failure necessitating digitalis therapy, 1.

The 17 fatal cases are analysed in Table III.

TABLE III.—*The Patients Who Died*

	Case No.	Age	Sex	Operations Performed	Anaesthetic	Previous Condition	Cause of Death
Respiratory	1	82	F	Removal of carcinoma of ovary	Thiopentone, 0·2 g., N_2O, oxygen, ether	History of previous pneumonia and chronic cough	Bronchopneumonia
	2	70	M	Strangulated inguinal hernia with resection of gut (E.)	Thiopentone, 0·3 g., N_2O, oxygen, ether	B.P. 200/120; severe arterio-sclerosis	Intercurrent lobar pneumonia
Cardiac	3	74	M	(1) Laparotomy and colostomy (2) Perineo-abdominal resection of rectum	(1) Thiopentone, 0·5 g., curare, N_2O, oxygen (2) N_2O, oxygen, ether		Cardiac failure. Post mortem: brown atrophy of heart muscle
	4	74	M	(1) Laparotomy and colostomy (2) Perineo-abdominal resection of rectum	(1) Thiopentone, 0·25 g., curare, N_2O, oxygen, ether (2) Thiopentone, 0·2 g., curare, cyclopropane	B.P. 230/120; severe arterio-sclerosis	Hypertensive heart failure
	5	73	M	Repair of right inguinal hernia and orchidectomy	Thiopentone, 0·7 g., N_2O, oxygen, ether	B.P. 180/100; some cough; senile Parkinsonism	Hypertensive heart failure
	6	70	F	Lotheissen's operation for Richter's hernia (E.)	Thiopentone, 0·4 g., cyclopropane, curare	B.P. 210/110; asthmatic heart enlarged	" "
	7	85	M	Prostatectomy	Cyclopropane	Fibrillating under digitalis; moist sounds both bases	Cardiac failure
	8	72	M	Caecostomy (E.)	Local	Pulsus alternans; moist sounds both bases	" "
	9	71	F	Above-knee amputation (E.)	Thiopentone, 0·15 g., cyclopropane	B.P 190/115; mild diabetic	Fibrillated: congestive heart failure
	10	70	M	Gastrostomy	Thiopentone, 0·25 g., curare, cyclopropane		Cardiac failure; toxaemia from subphrenic abscess; carcinoma of oesophagus
Secondary Emergency Operations	11	71	M	(1) Gastro-enterostomy (2) Laparotomy (E.)	(1) Thiopentone, 0·65 g., curare, cyclopropane (2) Local	Previous history of pneumonia; scattered rhonchi	No cause for death; terminal bronchopneumonia
	12	70	M	(1) Perforated peptic ulcer (E.) (2) Subtotal gastrectomy (E.) (3) Resuture abdominal wound (E.)	(1) N_2O, oxygen, ether (2) Thiopentone, curare, N_2O, oxygen, trilene (3) Curare, thiopentone, cyclopropane	B.P. 130/70; severe blood loss before second operation	General peritonitis from leaking duodenal stump and terminal bronchopneumonia
	13	80	F	(1) Subtotal gastrectomy (2) Ileo-transverse colostomy (E.)	(1) Curare, thiopentone, 0·7 g., cyclopropane (2) Thiopentone, 0·5 g., cyclopropane	B.P. 190/95. B.P. 60/? before second operation	General peritonitis from leaking duodenal stump
Carcinomatosis	14	70	F	Cholecystostomy (E.)	N_2O, oxygen, ether	Obstructive jaundice, diabetic	Carcinomatosis secondary to carcinoma of pancreas. Died day after operation
	15	70	M	Laparotomy only	Thiopentone, 0·5 g., curare, N_2O, oxygen, ether	B.P. 140/94	Died six weeks after operation; carcinomatosis
	16	72	M	" "	Curare, N_2O, oxygen, ether	B.P. 160/115; severe arterio-sclerosis	Died 7 days after operation; carcinomatosis with paralytic ileus
	17	74	F	" "	Thiopentone, 0·4 g., N_2O, oxygen, ether	B.P. 260/100	Died 3 months after operation; asthenia due to carcinomatosis

(E.) = Emergency operation.

Post-operative Complications

(*a*) *Wounds.*—Mild sepsis, 10; severe sepsis, 2; haematoma, 9; disruption, 1.

(*b*) *Thrombophlebitis.*—Due to intravenous drip therapy, 4: not due to intravenous drip therapy, requiring anticoagulant therapy, 3.

(*c*) *Chest.*—Major respiratory complications: severe bronchitis, 5; atelectasis (one case of bilateral basal collapse following a spinal analgesic), 5; bronchopneumonia, 3; pulmonary embolism, 1. It is to be noted that all these patients underwent an abdominal operation, and 12 of the 14 had pre-existing respiratory disease.

Minor Respiratory Complications

Under this heading are included all patients who had a raised respiratory rate for not more than three days after operation and cases of mild bronchitis. There was no relation to the type of operation, and of the 17 who suffered this complication 15 had pre-existing respiratory disease.

(*d*) *Intra-abdominal Complications.*—General peritonitis due to leaking duodenal stump, 2; persistent vomiting producing a salt-lack syndrome, 1.

Disposal of the Aged Patient

With the present shortage of hospital and convalescent beds, disposal of the aged patient requires some consideration. Such patients are not so fit as younger ones to return rapidly to normal domestic routine. *Often they live alone* and have no relatives to go to. Discharge from hospital therefore has frequently to be delayed. The almoner's department can often help with such cases by providing home helps or making suitable alternative arrangements. However, this problem is a very real one, and will require serious consideration in the future. Convalescent homes already have waiting-lists. At the present time the patient with an inoperable carcinoma who has been in hospital for a laparotomy often occupies a hospital bed until he dies. This is an undesirable situation in view of the great demand on hospital beds.

Conclusions

More patients over the age of 70 are submitted to major surgery than was the case 10 years ago.

Age alone is not a contraindication to surgery of any magnitude.

Care must be directed especially to the cardiovascular and respiratory systems.

Sepsis is a greater risk, and for this reason penicillin and sulphonamide therapy should often be used as a prophylactic measure

The aged should never be allowed to lie in bed.

Disturbance of the electrolyte balance is not well tolerated. This is well illustrated in three patients who required second operations as emergencies: in all of them vomiting or blood loss had grossly disturbed the fluid balance. All three patients died.

The commonest cause of a major chest complication is pre-existing respiratory disease in association with an abdominal operation. These complications are rarely fatal.

The commonest cause of death is cardiac failure arising in a hypertensive patient irrespective of the type of operation.

Some steps must be taken in the future to facilitate the care of the aged post-operative patient who does not require further active surgical treatment in a hospital bed. A comprehensive medical service must make better provision for this.

Summary

The results of major surgery in 99 patients over the age of 70 are surveyed.

The types of operation performed are enumerated.

The pre-operative management is considered.

The choice and administration of anaesthetic are discussed.

The post-operative management is outlined.

The 17 fatal cases are considered in detail.

Conclusions are drawn concerning the practice of surgery in the aged.

A plea is made for more adequate provision for the care of the convalescing aged patient.

All these cases were admitted under Sir Cecil Wakeley and Mr. E. G. Muir, to whom we wish to express our thanks for permission to survey these cases and for their guidance at all times. We are grateful to Dr. Vernon Hall and other members of the anaesthetic staff who administered some of these anaesthetics. We also thank Miss Fern and her staff for the kind co-operation of the Record Office.

Of nearly 7 million dollars spent on tuberculosis research in the United States in a 12-months period during 1947–8, about two-thirds were expended for the study of drugs in tuberculosis treatment. A survey undertaken by the National Tuberculosis Association showed that the greatest expenditure on tuberculosis research was by official agencies, with a total of nearly 4 million dollars, of which 3 million were allocated to chemotherapy investigations. Following closely behind the official agencies were manufacturing firms, with appropriations of over 2 million dollars. Research by firms manufacturing x-ray equipment was also carried out. Universities expended nearly ,000 dollars on tuberculosis research, with only 4,500 dollars allocated to chemotherapy. It is pointed out, however, that a large part of the studies financed by other agencies are actually carried out in institutions with university affiliation. Dr. E. R. Long, director of the medical research and therapy department of the National Tuberculosis Association, has stated that if streptomycin had not appeared so promising a drug "it is safe to say that much less money would have been expended for chemotherapeutic research, and much less, accordingly, for all research," but he emphasizes that streptomycin research has disclosed the need for more fundamental research in tuberculosis. "Had streptomycin proved as successful as the most optimistic enthusiasts anticipated," he stated, "had it proved, for example, as effective as penicillin in certain types of pneumonia, it is probable that interest in basic investigation on tuberculosis would have declined. Actually, however, streptomycin research has raised more problems than it has answered, and the new problems, such as the nature of the antibiotic mechanism and the reason for bacillary resistance to the drug, can be solved only by fundamental laboratory research."

Medical Memoranda

Chronic Progressive External Ophthalmoplegia

The idiopathic form of chronic progressive external ophthalmoplegia is rare enough to warrant a brief description of the following case.

CASE REPORT

The patient was a man aged 39 who was born in Rumania and had wandered about Eastern Europe and the Middle East. The family history revealed nothing significant. He had been in England since 1947. In 1933 he developed suppurating cervical glands; in 1935 he had pneumonia, and in 1942 typhoid fever. While he was in Egypt, at the age of 36, he noticed drooping of his left eyelid. In April, 1949, he came to hospital complaining of dizziness, double vision, and cough. There was marked ptosis of the left eye. Asymmetrical external ocular palsies were present, and the movements of the eyes were as follows:

	Right Eye		Left Eye	
Outwards	8°	20°	14°	16°
Inwards	12°		2°	
Upwards	30°	55°	2°	27°
Downwards	25°		25°	

The pupils were equal and circular, and reacted normally to light. On ophthalmoscopic examination the fundi were normal; an error of refraction (vision: R. 6/12, L. 6/36) was easily correctable, and perimetry showed very slight symmetrical diminution of the peripheral parts of the visual fields in each eye. No abnormality of other cranial nerves was observed, and all reflexes and sensations were unimpaired. Examination revealed no other physical signs.

The cerebrospinal fluid was normal, and the blood pressure was 130/80. Radiographs of chest and skull were normal, and the blood Wassermann reaction and Kahn test were negative. To exclude myasthenia gravis a therapeutic test was done (2.5 mg. neostigmine + 1/100 gr. (0.65 mg.) atropine), but, as expected, no improvement in the eye movements was observed.

COMMENT

In 1900 Wilbrand and Saenger studied 32 cases of chronic progressive external ophthalmoplegia and considered the condition to be a distinct clinical entity. The characteristic features, as they described them, are as follows: The onset is gradual, usually beginning in childhood, but may be delayed. Ptosis may be the first sign of the disease for a considerable time; years may elapse before there are signs of paralysis of the external ocular muscles, and diplopia may or may not occur. The internal ocular muscles remain normal and the health of the patient is not affected. According to these authors, "It is a striking feature of the affection that no other signs or symptoms develop indicating implication of other organs or other structures of the nervous system." Since the beginning of this century very few cases have been reported which belong to this group.

Altland (1909) described a case in which ptosis of the right eye occurred at the age of 22, and which developed bilateral ptosis (left incomplete) and immobility of both globes at 51. McMullen and Hine (1921) reported three cases, but one was excluded from this group because a subsequent examination revealed disease of other parts of the central nervous system. There are also reports by Langdon and Cadwalader (1928) and Farias (1941).

Fuchs (1890) thought that isolated forms of bilateral ptosis might be cases of primary myopathy. Ayres (1896) reported the disease in a boy whose maternal grandfather also suffered from it. Beaumont (1900) had 12 cases, and not only was there a familial incidence but in some there was an associated weakness in the distribution of the seventh nerve. This involvement of the central nervous system beyond the confines of the oculomotor nuclei is not in conformity with the description given by Wilbrand and Saenger.

The case described by Sandifer (1946), a man of 29, had bilateral ptosis for fourteen years, a complete external ophthalmoplegia, weakness of the orbicularis oculi, and certain cardiovascular changes. Although there was no family history, the resemblance of this case to some of those described by Beaumont cannot be overlooked. Sandifer found that, histologically, biopsy of the external rectus revealed myopathic degeneration, and he suggested that the lesion in chronic progressive ophthalmoplegia separated by Wilbrand and Saenger may sometimes be in the muscle and not in the oculomotor nuclei. Langdon and Cadwalader (1928), in their case of a woman of 81 with bilateral ptosis and almost immobile globes, found that the oculomotor nerves were comparatively small, the cells of the Edinger-Westphal nuclei were normal (this accounting for the internal ocular muscles being spared), but the cells of the remaining portions of the oculomotor nuclei showed some chromatolysis, pigmentation, and shrinkage. It is of interest to note that similar left-sided degeneration in the more proximal levels of the third nucleus was reported by Siemerling (1891) in a case of left-sided congenital ptosis with normal internal and external ocular muscles. This may indicate that the same aetiological factors are operative, whatever these may be, yet the two conditions are clinically distinct. Gowers (1893) speaks of "deficient vital endurance of the structures concerned," and his theory of abiotrophy is generally offered in explanation.

At present there seems to be a tendency to group together all cases of chronic progressive external ophthalmoplegia. Some of these cases may be familial, or they may be of myopathic origin (Nikitin, 1929; Elliott, 1939; Martin, 1939), while others may show evidence of involvement of different parts of the central nervous system in addition to the oculomotor nuclei. But since the prognosis is favourable in the condition separated by Wilbrand and Saenger (so far as the disease remains confined to the oculomotor nuclei), I believe it deserves to remain a distinct clinical syndrome, at least until the pathogenesis is elucidated.

K. K. HUSSAIN, M.D

My thanks are due to Mr. W. H. McMullen for his encouragement, and to Dr. W. H. Kelleher, physician-superintendent, Western Hospital, S.W.6, for permission to publish this case.

An Unusual Case of Rickets (Fanconi's Syndrome)

There are several atypical forms of rickets, but perhaps that associated with glycosuria, hypophosphataemia, and mild acidosis is the rarest; hence the interest of this case.

CASE REPORT

The patient, a female child aged 11 months, was sent from a maternity and child-welfare clinic to the paediatric out-patient department of the City General Hospital, Stoke-on-Trent, on November 19, 1948, for investigation of glycosuria. The mother reported that the child had been normal and healthy until a few weeks earlier, when increasing thirst had been noted and she had ceased to gain weight. She had become constipated also and was inclined to vomit. The mother was especially concerned because a son had died in 1941, at the age of 6 years, from what was stated to have been "nephritis and uraemia." The mother volunteered the information that he had had "sugar in his water" from the age of 12 months, and that the onset of his illness had been associated with thirst and retardation of growth. Further questioning elicited that the father had died from a renal calculus, the mother herself being apparently normal, as is her only other child, a girl aged 7.

On clinical examination the patient was a pale fragile child, with two teeth, and was able to stand and to say a few words. Her weight was 16 lb. (7.26 kg.). There was evidence of recent loss of weight, and she appeared dehydrated. She had well-marked rickets, with bossing of the skull, rachitic rosary, and thickening of the lower ends of the radii. Her abdomen was distended, and faecal masses could be felt in the left iliac fossa. No abnormal findings were noted in her throat, ears, chest, or in the cardiovascular and central nervous systems.

Special Investigations.—Urine: This showed an acid reaction, a trace of albumin with 1% of sugar (proved to be glucose), an excess of amino-acids, and no ketone bodies; microscopy revealed a few red blood cells, scanty pus cells, and numerous granular casts. *Blood:* Urea varied between 34 and 42.6 mg per 100 ml.; sugar, 83 mg. per 100 ml.; serum phosphorus, 2 mg. per 100 ml. (normal 4–5 mg.); serum calcium, 9.3 mg. per 100 ml. (normal 9–11 mg.); serum alkaline phosphatase, 10.1 units (normal 3–13); serum acid phosphatase, 3.2 units (normal 0.5–5); plasma proteins, 4.75 g.%; alkali reserve, 50 vols. CO_2%; Wassermann reaction negative. *Radiology* A straight radiograph of the abdomen and radiograph of the skull and pituitary fossa showed no abnormality, and I.V.P. was deemed inadvisable owing to the child's general condition A radiograph of the wrists showed decalcification of the bones with rickets. A glucose-tolerance test confirmed the glycosuria to be renal in origin.

COMMENT

The association of rickets, glycosuria, hypophosphataemia, and mild acidosis is extremely rare. The first cases were reported in 1926 by Schier and Stern, others being later reported by Fanconi (1931), by whose name the syndrome is sometimes known, and De Toni (1933).

The aetiology of the condition is uncertain, but it is known to have a familial incidence. It is said to be due to a defect of the renal tubules which renders incompetent the reabsorption of glucose, amino-acids, and phosphates This explains the increased amino-acids in the urine, the often decreased blood proteins, the glycosuria of renal type, and the hypophosphataemia (the last-mentioned being sometimes the cause of renal calculus). The defect is said to be in the proximal renal tubules, where glucose and phosphates are normally reabsorbed in the form of phosphate esters. Stowers and Dent (1947) have demonstrated on post-mortem material that phosphatase, which is essential for the formation of these esters, is absent from the proximal renal tubules, where it is normally abundant, and

they believe this to be the major defect in Fanconi's syndrome.

The above case seems to be a classical example of the condition, and has several features of note. First, the family incidence : there seems to be no reason to doubt that the child who died in 1941 showed the main features of the syndrome, and it is probable that the father's renal calculus was related to the condition of his children. Unfortunately no notes of either of these cases are available. Secondly, in spite of the fact that the child had received adequate anti-rachitic treatment (fortified cod-liver oil) since birth, she had developed gross rickets by the age of 11 months. Finally, the early age at which diagnosis was possible is of interest.

The condition being a congenital and often hereditary defect of the renal tubules, treatment is unfortunately of little avail.

Acute Psychosis Caused by Dextro-amphetamine

The following case is of interest because of the small amount of the drug taken.

CASE REPORT

A petty officer stoker mechanic aged 29 reported sick with a five-years history of headaches and depression. His M.O. found no organic cause for the headaches and, in view of the depressive element, prescribed dextro-amphetamine. The patient was given 14 5-mg. tablets and instructed to take two daily. At 6 a.m. on the following morning he was found stuporous on the bedroom floor. He had been incontinent of urine. He was able to state that before retiring he had taken 11 tablets (55 mg.) of dextro-amphetamine. When he regained consciousness in hospital he thought he saw a piece of paper going up the side of the door. He then complained that somebody was putting his finger on the top of the door and taking it away quickly. He also imagined he saw smoke coming through a partly open door, and later in the forenoon he stated that there were flashes of light going across the bed. He had auditory hallucinations at the same time, and he felt annoyed because nobody shared these experiences. Similar hallucinations continued during the remainder of the day. The next morning he was cheerful, co-operative, and relaxed. Consciousness was clear, his thought and conversation were coherent and relevant, and he was not at all depressed or irritable. He was still hallucinated and had come to the conclusion that someone had been arranging these phenomena in order to test his reactions to them. He lacked insight and could not accept any suggestion that he had been hallucinated. He had no further hallucinations after his first morning in hospital, and he developed good insight. His thought and behaviour rapidly became normal and he had no further symptoms except occasional headaches.

COMMENT

The dose taken by this patient appears to be the smallest on record to have precipitated a psychotic state. Probably a larger dose would have been required if he had taken the drug previously and had thereby gained some tolerance. Idiosyncrasy to small doses, resulting in circulatory collapse, is reported by Davies (1937), Norman and Shea (1945), Shorvon (1945), Mutch (1948), Sargant and Slater (1948), and others. Idiosyncrasy was evidently responsible for one of the two recorded fatalities—that of a student aged 25 who collapsed and died after taking 30 mg. of amphetamine sulphate daily for a few days (Smith, 1939). The other death occurred after the accidental ingestion of 40 mg. of amphetamine by a 1-year-old child (Hertzog *et al.*, 1943).

Eight cases are recorded of acute psychosis caused by amphetamine and its dextrorotatory isomer. Young and Scoville (1938) administered amphetamine to two narcoleptics, who both developed a paranoid psychosis after a few weeks. The amount of the drug taken was uncertain, but was of the order of 30 to 40 mg a day. Norman and Shea (1945) report the development of somatic, visual, and auditory hallucinosis in an alcoholic aged 49 who had been taking a daily dose of 250 mg. of amphetamine for five years. Monroe and Drell (1947) describe a further four cases of hallucinations and ideas of reference amongst prison inmates who had been ingesting strips of amphetamine from inhalers. One had taken 93 mg. and another 250 mg. The amount consumed by the other two is not specifically stated, but was probably of the same order, since each inhaler contained 250 mg. of amphetamine base. Schneck (1948) reported visual hallucinations and delusions in a man who had consumed one and a half amphetamine inhalers within 36 hours.

We are indebted to Surgeon Rear-Admiral J. A. Maxwell, C.V.O., C.B.E., F.R.C.S., K.H.S., medical officer-in-charge, R.N. Hospital, Haslar, for permission to publish this case.

The important effect on stressed "perspex" windows of solutions used for the disinsectization of aircraft is described by Whittingham and Galley in the *Monthly Bulletin of the Ministry of Health and the Public Laboratory Service* (1949. **8**, 186). Some insecticide solutions facilitate the crazing of these windows, a process which manifests itself in the formation of cracks varying from a surface frosting to deep, highly reflecting fissures. This causes a weakness which in pressurized aircraft may lead to the window blowing out in flight—a serious matter for the aircraft and its occupants at high altitudes. Four common insecticides were tested in the laboratory for their effect on stressed "perspex," and a wide variation was demonstrated in the intensity of their action. One solution containing methylene chloride, for example, caused instantaneous crazing when sprayed on to the window material. Whittingham and Galley's findings indicate the importance of consulting aircraft constructors and experts on materials used in aircraft in the development of new insecticides for this use.

Reviews

THE CARE OF THE OLD

Geriatric Medicine. By E. J. Stieglitz, M.D., F.A.C.P. Second edition. (Pp. 773; illustrated. £3.) Philadelphia and London: W. B. Saunders Company. 1949.

Age is Opportunity. (Pp. 118; illustrated. 2s. 6d.) London: The National Council of Social Service, 26, Bedford Square, London, W.C.1.

The two books are symptomatic of the increasing interest in the care and welfare of the aged. In a sense they are complementary, for the first sets out to discuss the diseases from which the aged suffer, with their prevention and their treatment, while the second gives much useful advice and information to those who wish to see elderly persons given the greatest opportunity possible for their own happiness.

Unfortunately, Stieglitz and his 46 co-authors have not made up their minds on what they are attempting to do. As a result, their book does not completely satisfy any one criterion. It is not a textbook of medicine, because it presupposes much fundamental knowledge of medicine; yet it is not a handbook for the doctor who wishes to do something for his elderly patients, because it treats in too much detail of all diseases affecting all patients. It does not limit its lesson to modifications or improvements in the diagnosis and treatment of old people suffering from general disease.

One can except from this generalization the articles written by Stieglitz himself, both on the general approach to and on the philosophy of the medical care of the elderly, and on hypertensive arterial disease From these sections there is much that can be learned and much for the intelligent reader to ponder over. The author comments with a refreshing sanity on the interpretation of a raised blood pressure, pointing out the irrelevance of a single reading and emphasizing the importance of the time factor in prognosis. The instructions for treatment are clear and detailed, and show how the patient with early hypertension can enjoy a reasonable life without being a burden to himself or his relations by reason of a host of dietetic fads and restrictions. Similarly, Monroe's article on diseases of the joints comes near to being a model of clear thinking and wise treatment. His advice on the management of a patient suffering from early rheumatoid arthritis is excellent. He realizes that the hopeless deformities so frequently seen are not inevitable, and gives in some detail his own method of preventing their occurrence.

Few of the other authors go into sufficient detail to make this expensive book of much practical value to the doctor who wishes to do his best for his elderly patients. Old people certainly have their own problems: it is true that there are no major changes in the concept of treatment between the middle-aged and the aged, but the difference between success and failure in this specialty lies in the ability to devise means of overcoming the effects of lengthy illness and even longer deformity. Little attention is given in this book to considering how best to prevent the onset of illness among the elderly, and sufficient emphasis is not laid upon the remarkable capacity for rehabilitation possessed by these people, provided it is realized that the response to treatment will be slow and that much patience will be needed to obtain success. This does not need to be the patience of inertia; the treatment is of interest because of the infinite variety of detail needed to achieve a successful result.

Reference to the occurrence of pulmonary tuberculosis among the elderly is interesting and important, and one wonders how many children have been infected by a loving grandparent suffering from a "touch of bronchitis." But it is surprising to read suggestions for the treatment of Eustachian deafness with radium: experience gained in this country during the war has shown the dangers of this practice.

The handbook issued by the National Old People's Welfare Committee gives good advice to any body, voluntary or municipal, that wishes to take an intelligent interest in the welfare of the elderly. It deals systematically with their wants, and shows how these can best be satisfied. It gives, therefore, indications of how the elderly can be kept in good health, and how they can be prevented from becoming a burden to the community by sinking into a state in which they need to be admitted to hospital for long periods. Regular visiting and the establishment of clubs will not only combat the loneliness which is one of the great dreads of old age, but will enable disease to be recognized while it is remediable. Provision of meals will help to prevent the varied types of malnutrition which are found among the elderly. A useful occupation will keep the mind alert and active, and its provision should help finally to dispel the idea that the aged are incapable of learning new trades. Advice on the setting up of homes and other forms of housing will go far to ensure that the older members of the population shall be housed in as suitable surroundings as their younger countrymen, and will do much to keep them well. This is a useful book that should be widely read.

AMULREE.

HANDBOOK OF FRACTURES

Fractures and Dislocations in General Practice. By John Hosford, M.S., F.R.C.S. Second edition revised by W. D. Coltart, F.R.C.S. General Practice Series. (Pp. 288; 87 illustrations. £1 1s.) London: H. K. Lewis and Co. 1949.

Modern methods in the treatment of fractures, with the necessity for repeated radiographic examination, plaster work, physiotherapy, and other ancillary services, have made it inevitable that most fractures should be treated primarily in the fracture services of the hospitals. More often than not the general practitioner has neither the facilities nor the apparatus for the efficient handling of fractures, other than those of a minor nature. Nevertheless, it would be unfortunate if the family doctor were to lose touch with modern developments in treatment. He may no longer be responsible for the details of the local treatment of the fracture, but very often the general supervision of patients under treatment at the fracture clinic will fall to his care. His advice and opinion will often be sought; and he will be called in if unexpected symptoms should develop in the intervals between the patient's visits to the clinic.

The second edition of this book has been revised considerably to suit the changed conditions that now prevail. It does not set out to teach the practitioner how to treat a fracture: it is designed to give him an up-to-date account of the broad lines on which fractures and dislocations are treated in hospital. The book can be commended for its clear descriptions, accuracy, and conciseness. It should fulfil well the purpose for which it has been designed, and it may prove even more successful as a short handbook for students.

J. C. ADAMS.

NEONATAL MORTALITY

Fetal and Neonatal Death. By Edith L. Potter, M.D., Ph.D., and F. L. Adair, M.D. Revised edition. (Pp. 173; illustrated. £1 10s.) Illinois, Chicago: University of Chicago Press. Great Britain and Ireland: Cambridge University Press. 1949.

All those concerned with the care of the newborn baby have used "Potter and Adair" since it first appeared in 1940. A new and revised edition, which incorporates new work on the Rhesus factor and the effect of rubella upon the foetus, is therefore most welcome. It is of great importance to consider stillbirths as well as neonatal deaths to gain a complete picture of loss of life at this period, and the study of the problem in the necropsy-room or as an exercise in statistics is well described. It is inevitable that the references should be almost entirely to American literature, and it seems strange to find respiratory difficulties at birth discussed without any reference to Barcroft's work. It would be a fascinating task to relate the United States statistics to those of other countries, as Professor C McNeil did with his Scottish figures in 1942.

The authors' approach to a subject which still requires much exploration is essentially that of pathologists. As will be gathered, the effect of this monograph upon the reviewer is to make him eager to see it much enlarged: it is excellent as far as it goes. ALAN MONCRIEFF.

PATHOGENESIS OF INFECTION

Klinische Infektionslehre. By Professor Felix O. Höring. Second edition. (Pp. 245. M. 18.) Berlin: Springer. 1948.

Professor Höring's *Clinical Study of Infection* is an unusual book. It is an attempt to bridge the gap between bacteriology and immunity on the one hand and clinical medicine on the other. It is not a textbook or a monograph, but rather an essay with pathological physiology as its central theme. Health and illness are taken as abstractions; the host and the parasite are the only concrete realities. The author revolts from the concept of disease resulting from the blind operation of chance, something imposed on the host from outside. The individual cannot be thought of apart from his environment. The relation of the host to the parasite is not one of enmity but essentially an attempt at mutual adaptation with symbiosis as its goal. Medical bacteriology is therefore merely a branch of oecology.

Starting from this thesis, the author examines the different reactions of tissues to the parasite, classifying them into normal, anergic, and hyperergic. He then divides all infectious diseases into three categories: (*a*) the cyclical diseases characterized by a predictable course—incubation period, riod of generalization, period of localization in the gans; (*b*) the local diseases, characterized by a focus of inflammation that spreads only by direct continuity and pursues an irregular course; and (*c*) the septic diseases, characterized by an inflammatory focus that is in direct communication with the blood stream, thus enabling the particular types of parasite associated with these diseases to give rise to generalized manifestations. Further subdivision follows, and ten possible courses are described for the infectious process. Each of the infectious diseases is then briefly examined, and classified according to its pathogenesis into one or other of the numerous theoretical categories laid down.

This form of abstractive treatment is perhaps more congenial to the Teutonic than the English mentality, but both clinicians and bacteriologists may find something stimulating in the author's method of approach to a well-worn subject. G. S. WILSON.

SATURDAY DECEMBER 17 1949

VITAMIN B_{12} AND PERNICIOUS ANAEMIA

Vitamin B_{12}, a crystalline anti-pernicious-anaemia factor of great potency, was isolated almost simultaneously in 1948 in this country and in the U.S.A. We have already commented[1] on some of the reports describing its properties and uses. Intramuscular injections of a few microgrammes of this compound, which appears to possess all the activity usually associated with liver extracts, causes remissions in pernicious anaemia, sprue, steatorrhoea, and nutritional macrocytic anaemia. The only other substances which have such a powerful action in minute quantities, though in their case a harmful one, are the radioactive element plutonium and botulinus toxin. Calculation shows that not more than a few hundred molecules of vitamin B_{12} are necessary for the maturation of one red cell. Reports on the use of vitamin B_{12} have so far been confined to small series of patients treated with varied amounts of the vitamin and followed up for very short periods. In this issue of the *Journal* we publish two articles by workers who have played leading parts in the isolation and testing of this compound. That by Dr. E. Lester Smith gives the story of the work which resulted in its discovery. In the 22 years since Minot and Murphy first discovered the effectiveness of liver therapy in pernicious anaemia there has been a gradual advance in methods of purifying liver extracts, though it is now known that these purified extracts contained less than 1% of the active constituents. This was due to lack of a suitable method of separation from inert material (eventually overcome by partition chromatography), the extremely small quantity of vitamin B_{12} present (less than 1 g. in 4 tons of liver[2]), and the absence of convenient methods of assay. The success of Lester Smith's fractional crystallization depended upon the results of clinical trials of more than 80 samples carried out by Dr. C. C. Ungley, the author of the second paper in this issue. In this type of work the greatest care and patience are needed to avoid false results, and it is to the credit of the clinical workers that they were able to lead the laboratory workers along the correct path.

Dr. Ungley's carefully planned investigation of the treatment of pernicious anaemia by injections of vitamin B_{12} was carried out on 53 cases, the largest series yet published. He took great care to ensure that responses were not due to spontaneous remission or to factors in the diet, and he was able to offset the effect of variation in the initial red-cell count by the use of statistical methods. Having worked out a logical scheme of dosage Ungley is now able to say with greater certainty than any previous worker how much vitamin B_{12} is required to treat patients with pernicious anaemia. It seems that a single dose of 10 μg. produces as good a response, judged by reticulocyte increase or, better, by the rise in the total red-cell count over a period of 15 days, as is usually obtained with ordinary liver extracts. Larger doses give even better results, and the amount required to restore the red cells to 4.5 million or more in 32 cases ranged from 15 to 140 μg. These amounts led also to an increase in white cells and platelets and to clinical recovery. Twenty-one patients have been followed up for six to fifteen months while receiving 10 μg. every two weeks, and only three have not been maintained in an entirely satisfactory state. No fresh neurological symptoms appeared, and those already present improved or at least did not progress. Ungley considers the results of treatment of eight cases of subacute combined degeneration of the cord to be as good as those obtained with liver extract, either crude or refined. This contrasts strongly with the results of folic acid therapy reported recently in this *Journal* by Israëls and Wilkinson,[3] who concluded that folic acid should never be given to patients with subacute combined degeneration of the cord. Ungley suggests a dosage schedule consisting of 40–80 μg. initially, 20 μg. weekly for three months, and 30 μg. every three weeks thereafter for the uncomplicated case of pernicious anaemia, with double these amounts and more frequent administration when neurological symptoms are present.

The use of microbiological methods of assaying vitamin B_{12} activity, developed in the U.S.A. during the work which led to its isolation there, enables the strength of liver extracts to be measured in terms of a pure substance. Dosage will thus cease to be empirical. The isolation of vitamin B_{12} from the metabolism fluid of cultures of *Streptomyces griseus* (used in the manufacture of streptomycin) is referred to by Lester Smith, and commercial production from fermentation liquors is now practicable. The use of the pure vitamin may obviate the reactions which occasionally occur with liver extract and will certainly enable larger amounts of the anti-pernicious-anaemia factor to be administered. Thus the outlook for patients with cord changes may be improved. No doubt, however, further discoveries will soon be made. Already there are known to be

1 *British Medical Journal*, 1949, 2, 694.
2 Smith, E. L., *Nature, Lond.*, 1948, 161, 638.
3 *British Medical Journal*, 1949, 2, 1072.
4 Spies, T. D., Stone, R. E., Lopez, G. G., Milanes, F., Toca, R. L., and Aramburu, T., *Lancet* 1948, 2, 519.

two, probably three, active substances in the crystalline fraction, and their relationships and chemical structure are being studied. The part played by folic acid and thymine[4] still remains a mystery. On the clinical side, too, there are many unanswered questions. The nature of the "intrinsic factor" is still unknown. The source of vitamin B_{12}, whether dietary or the result of bacterial synthesis in the gut, is uncertain. There is no satisfactory explanation why some patients develop subacute combined degeneration of the cord when anaemia is only moderate or even absent and other patients with severe anaemia do not develop it, why spontaneous remissions occurred before liver was used in treatment, or why some patients are, or become, refractory to treatment with liver extract. The discovery of vitamin B_{12} has already helped the search for the answer to these and other questions.

THE EYES IN MALNUTRITION

It is not surprising, since the normal eye is a most sensitive and delicately poised optical instrument, that optical abnormalities should frequently occur as an effect of disease or that they should be given prominence when they are a characteristic feature of any particular illness. Besides being a secondary effect of disease, however, eye lesions may sometimes be the first signs of dietary deficiency. In recent years much new knowledge has been gained about nutritional requirements, and many books and papers have been written around clinical and experimental observations on the state of the eyes in various forms of malnutrition. Dr. Hugh Stannus's scholarly and critical essay on "Nutritional Eye Disease,"[1] for which he was recently awarded the Treacher Collins Prize, is therefore to be welcomed as a valuable review of this important subject. In his earlier chapters Stannus assumes that disorders of nutrition may result from senescence, inborn errors of metabolism, endocrine derangements, metabolic diseases, and various congenital deformities, dystrophies, and abiotrophies, and he discusses many pathological conditions, both common and rare, in which the eyes are affected, though it may be questioned whether nutritional factors are concerned in all of them. In his description of the biochemistry and metabolism of the various parts of the eye he points out that the lens is completely isolated from any blood supply and is believed to have its own internal auto-oxidation system, in which ascorbic acid and glutathione, both present in relatively large quantities, may be vitally concerned.

Stannus devotes most space to a discussion of the effect of either primary or secondary deficiencies of individual nutrients on the structure and function of the eyes, with particular emphasis on the effects of deprivation of vitamins. According to present evidence, vitamins A, B_1, C, and riboflavin seem to be more important than others for maintaining the health of the eyes, though Stannus briefly reviews the whole range of vitamins and the general effects of their deficiencies. As examples of the various ways in which nutritional deficiency may affect the eyes the four main lesions which can result from deficiency of vitamin A have special interest. In human beings and in rats avitaminosis A frequently gives rise to *xerophthalmia* and keratomalacia. These abnormalities are generally regarded as the classical signs of deficiency of the vitamin and frequently cause permanent blindness in Eastern peoples. In rats deficiency of vitamin A during pregnancy often causes ocular defects in the offspring.[2] In dogs deficiency of the vitamin may disorganize bone growth, and stricture of the optic nerve may result from occlusion of its foramen.[3] Deficiency of vitamin A also causes defective dark adaptation: the abnormality in this instance may be traced to a defective formation of visual purple, a photosensitive pigment present in the retinal rods. At least one form of this pigment, if Stannus's view is accepted that a group of pigments is involved, consists of vitamin A in combination with protein. Deficiency of a single vitamin, therefore, may lead to permanent blindness by three distinctly different anatomical routes. A serious functional disturbance also results if the same vitamin is not available to take part in the complicated mechanism of the retina; for this it takes on a form in which it is unknown in any other tissue.

Deficiency of vitamin B_1 causes similar optical lesions in diseases arising in widely different circumstances. Thus Wernicke's encephalopathy,[4] a disease in which sight is affected by lesions in the periventricular grey matter of the brain, with varicose deformities of the blood vessels and petechial haemorrhages, was described long ago in alcoholic patients, and was later considered to be associated with a secondary deficiency of vitamin B_1. Subsequently a very similar picture was observed in the "Chastek paralysis" which afflicted artificially reared silver foxes when they were fed upon raw fish. Research soon indicated that the fish contained a toxic substance capable of inactivating vitamin B_1, which was effective in the treatment of the disease. Finally, Wardener and Lennox[5] noticed a similar syndrome, often fatal, in a large number of prisoners of war at Singapore whom they considered to be suffering from "cerebral beriberi." Thus secondary deficiencies of

vitamin B_1 caused by two different toxic agents, or by prolonged and severe dietary deficiency, all eventually lead to the development of similar syndromes. In riboflavin deficiency there is a heaping up of sodden epithelium on the palpebral commissures, in common with all orifices of the body, the typical signs having been observed by Stannus in malnourished individuals nearly forty years ago. The patients complain that their eyes itch and burn, and visual acuity is sometimes poor. Stannus, however, disputes the claims originally made by Kruse and Sydenstricker[4] that a deficiency of riboflavin may be diagnosed by slit-lamp examination of the vessels in the limbus, since other factors have to be taken into account. Dr. Stannus concludes his monograph with a comprehensive account of the optical abnormalities which were frequently observed in prisoners of war in the Far East subsisting on diets deficient in both quantity and quality. In these circumstances retrobulbar neuritis was often a prominent symptom, probably associated with riboflavin deficiency.[7] Nystagmus with oto-neurological symptoms was also common and believed to be an early manifestation of pellagra.[8] Pick's visions, or the so-called partial visual vertigo, were another disturbing feature; the patients saw jumbled print when they attempted to read, and sometimes had the impression that their companions left the room by walking through the wall.

VITAMIN E THERAPY

The difficulty of deciding whether vitamin E has any real value in the treatment of human diseases was emphasized by the contradictory opinions expressed at the International Conference on Vitamin E which was held in New York earlier this year and on which we commented at the time.[1] Massive doses of α-tocopherol were claimed by Dr. Evan Shute and others who belong to his school of thought to be effective in the treatment of cardiovascular diseases, chorea, ulcerations, burns, multiple sclerosis, urethral strictures, Dupuytren's contracture, Peyronie's disease of the penis, and even diabetes. Most of these claims, however, were contested by other investigators, who described carefully controlled trials in which they had failed completely to observe any benefit from vitamin-E therapy. In spite of these severe criticisms vitamin E has continued to be widely prescribed in Canada and the U.S.A.

Recent reports have increased doubts about the value of vitamin-E therapy. In the treatment of a small, carefully selected series of cases of angina pectoris Ravin and Katz[2] found that tocopherol was valueless. Bensley and his colleagues[3] were equally unsuccessful in a careful trial of its alleged beneficial effects in diabetes. To offset these disappointments, however, the use of tocopherol in two recent investigations, reported elsewhere in this issue, appears to have achieved a fair measure of success. Dr. G. Russell Thomson (p. 1382) has tested Steinberg's claim that Dupuytren's contracture is influenced favourably by massive doses of vitamin E. Most of his early cases responded well, and complete extension of the fingers was often restored. The vitamin was also beneficial in the later stages of the disease, but to expedite cures the palmar bands were divided by operation. These observations, however, are open to the criticism that no control cases were given placebos. though confirmatory evidence that the vitamin has a plainly recognizable effect on the diseased tissues might perhaps be inferred from the pain which was often experienced in the palmar bands before the contracture began to respond. Dr. H. C. McLaren (p. 1378) has studied the value of tocopherol in preventing flushing, sweating, and insomnia after artificial induction of the menopause by treatment with radium or deep *x* rays or by hysterectomy and oöphorectomy. Temporary relief was obtained in about 60% of his cases. Since the remaining 40% were relieved by stilboestrol, it is clear that tocopherol is less efficient than are oestrogens in preventing flushings, but it has the advantage of seldom causing the resumption of menstruation. Some of the patients were given placebos for a few weeks before their treatment with tocopherol was begun; only one out of eighteen was cured.

The results of these two investigations raise hopes that vitamin E may have real value in the treatment of certain diseases, even if the more extravagant acclamations of its virtues have to be discounted. Animal experiments have left no doubt that the vitamin is essential for most species, and that the lesions which result from its absence are remarkably diverse. Thus its role in maintaining gestation, which led to its discovery some 25 years ago, is only one of the many manifestations of its activity. Other lesions caused by deprivation of this vitamin are muscular dystrophy, brown coloration of the uterus and skeletal muscles, encephalomalacia, exudative diathesis, and dental abnormalities. Animals whose diets are deficient in vitamin E use and store vitamin A inefficiently, and their fat deposits are turned brown when large amounts of cod-liver oil are given. When the diet is deficient also in protein the animals are particularly vulnerable to liver injuries, whether occurring spontaneously or after the administration of chloroform or other toxic substances. The erythrocytes of deficient animals are unduly liable to haemolysis. From the results of animal experiments, therefore, it would not be surprising if deficiency of vitamin E were found to be associated

with several widely different human diseases. But there is still no evidence that concentration of vitamin E in the blood plasma is particularly low in any of the diseases which it is reported to benefit, or that the food eaten by the patients suffering from these diseases has been deficient in the vitamin. The doses claimed to be effective, moreover, are usually greatly in excess of what is thought to be the normal daily requirement. Shute has concluded that tocopherol in large doses has therapeutic effects which are distinct from its physiological effects at normal intakes. Another possibility is that defects in the tissues may increase requirements for tocopherol, so that the amounts normally supplied by the blood may become inadequate.

Perhaps the most regrettable feature of tocopherol therapy, at its present state of development, is its great expense. Thus in McLaren's investigation an average course of treatment consisted of 18.5 g. of tocopherol given over 37 days, and the cost was £7. For other diseases Shute recommends permanent dosing, which means a constant expenditure of over £1 per week. This heavy cost would obviously be justified for a drug clearly proved to prolong life or prevent disablement. but for a remedy whose efficacy is still in doubt the price seems far too high. For the present tocopherol might justifiably be prescribed in Dupuytren's contracture and in cases of menopausal flushings in which the administration of oestrogens is contraindicated. It may perhaps be worth a trial in Buerger's and Peyronie's diseases. Its value in the treatment of more common diseases is in most instances very questionable, and its prescription should await the verdict of carefully organized research

SPENS AWARDS TO BE CONFIDENTIAL?

The Council of the B.M.A. and the Central Consultants and Specialists Committee have formulated their views on the "Special Distinction Awards" in a statement published in this week's *Supplement*. They have decided that neither body, nor the Regional Consultants Committees, should have a hand in putting forward the names of suitable recipients of the awards. They recommend the Advisory Committee on Merit Awards to form, after consultation with hospital boards, selection committees in each region comprised of "distinguished practitioners of consultant status who are not themselves interested in merit awards (i.e., being already in receipt of the highest award or retired from practice)." The Council and the Consultants Committee have also suggested criteria for assessing merit.

One recommendation calls for comment: "It would be undesirable that any publicity should be given in the lay press to the practitioners who receive awards, but at the same time information regarding the awards should be available to the profession. If this principle is accepted it follows that there should be no publication of lists of recipients even in the medical press." If there is no publication the information cannot be available to the profession. It is recommended that this information shall be available to *part* of the profession—namely, the Joint Committee and its constituent bodies; boards of governors, regional boards. medical committees, and medical advisory committees "Apart from this the boards should be instructed to regard information relating to awards as confidential." It is not for the *Journal* to criticize this recommendation of the Council of the B.M.A. to the Advisory Committee on Merit Awards. The fact that it has seen fit to make such a recommendation is in itself a comment on the peculiar innovation in our professional life that has been introduced by this method of augmenting consultants' incomes.

These awards have often been described as prizes—even compared to Nobel prizes. Men like to honour those who win prizes and gain professional distinction for merit in their work. If the recommendation of partial secrecy is acted on, then something quite exceptional will have happened in the profession of medicine—and in the history of prizes and awards. The reasons for asking for partial secrecy are no doubt compelling; the fact that the Consultants and Specialists Committee demanded it is proof enough of this. Secrecy is a form of censorship, and if we countenance it ourselves it may be less easy to fight against it if others should attempt to impose it on us.

TRAUMATIC DIABETES INSIPIDUS

Diabetes insipidus has long been recognized as a rare sequel of head injuries.[1-4] Porter and Miller[5] have recently reviewed the subject, basing their observations on 18 cases. The condition was noted in 13 out of 5,000 cases of non-penetrating head injury at the Military Hospital for Head Injuries at Oxford. In all cases the injury was severe as judged by the length of the post-traumatic amnesia, which was less than two days in only one case The diabetes insipidus was well controlled by posterior pituitary extract in the 14 cases in which it was used: no case resistant to this treatment was encountered. Eleven patients recovered spontaneously within nine months; one was improving satisfactorily after 15 months; and in the other six there was no evidence of recovery at intervals of from 13 months to eight years after the head injury.

A point of special interest in this study is that the appearance of diabetes insipidus may be delayed. It is obviously difficult in patients whom the injury has made stuporose and incontinent to be quite sure when polyuria and polydipsia start, but the authors are confident that in the majority of their patients these symptoms developed from nine to 30 days after injury. This finding is in keeping with experimental diabetes insipidus in dogs,[6] in which there may be a considerable interval after traumatic hypothalamic lesions before diabetes insipidus occurs. If at the time of operation the pitressin-secreting tissue of the pituitary is also removed diabetes insipidus develops immediately, and it is thought that the delay is due to pitressin

being secreted for a time by the denervated neurohypophysis. A record was kept of the concomitant intracranial damage in these patients; injuries of the optic chiasm, optic nerves, and olfactory nerves were frequent, but in one case only was there undoubted clinical evidence, apart from the onset of diabetes insipidus, of hypothalamic damage. This was a man who developed an adiposo-genital syndrome during the 15 months following his head injury. The adiposo-genital syndrome has been reported by other workers[7 9] as a symptom of hypothalamic damage following head injury, and also narcolepsy.[7 8]

No post-mortem studies could be made in Porter and Miller's series of cases, and, as is so often true in non-penetrating head injuries, the exact location and mechanism of the neurological damage is to some extent speculative. The authors think that the damage was probably in the pituitary stalk, due to stretching when the brain was displaced at the time of injury, and that some patients recover completely because not all the fibres in the stalk are completely severed. They suggest that the relative rarity of other hypothalamic symptoms is due to the early death of most patients who have severe hypothalamic injuries.

Two earlier case reports provide useful information about the site of the injury in traumatic diabetes insipidus. Reverchon and Worms[10] described the post-mortem appearances in a case in which the hypophysis was completely unrecognizable and was reduced to a nodular mass surrounded by a fibrous capsule. Unfortunately no special mention was made of the hypothalamus, presumably because the case was reported at a time when attention was directed to the pituitary rather than the hypothalamus in the pathogenesis of the condition. The case of Maranon and Pintos[11] is more instructive. A boy was accidentally shot by a pistol through the middle of his forehead from a distance of three metres; he did not lose consciousness, felt no pain, and actually went on playing. One month afterwards he developed excessive thirst and polyuria, and 16 months later an adiposo-genital syndrome. He died following an exploratory craniotomy, and at necropsy the bullet was found lying in the floor of the third ventricle with its point in the direction of the pituitary stalk. There was a fibrous capsule around the bullet involving the tissue of the stalk, but there was no evidence of damage to the pituitary. These findings are of particular interest, since they also were described before attention had been directed to the hypothalamus and pituitary stalk; they agree closely with the results of Magoun and Ranson's[12] experimental work on the cause of diabetes insipidus and the importance of the anterior part of the hypothalamus and the fibres running through the pituitary stalk from the supra-optic nuclei to the posterior pituitary.

ERYTHROCYTES IN LIVER DISEASE

The important role of the liver in haemopoiesis has been recognized since the classical work of Minot and Murphy,[1] and much information has since been obtained about disturbances of red-cell formation in patients with hepatic disease. The most frequently recorded deviation from the normal blood picture is an increase in the size of the red cells, the reported incidence of this abnormality varying from 25 to 100%. Much of this variation is probably attributable to differences in methods of observation used by different observers. Quite logically, therefore, Larsen[2] in Oslo, before re-examining the effect of hepatic disease on red-cell size, examined the whole question of the technique of cell measurement and the possible errors therein. The thoroughness with which he has tracked down and exposed sources of error is reminiscent of the meticulous work of the German pathologists in their heyday. The work is in fact but one more example of the leading part Scandinavian workers are playing in medical research. The author has not hesitated to apply every technique at his disposal, and his use of the statistical method is a model of its kind for the exposition of error and the elucidation of significance.

Among the errors which Larsen discusses, and then avoids in his own work, are those due to personal qualities in individual assistants. These are of great psychological interest. For example, some are apt to "draw towards the centre," which makes the frequency distribution curve too high and too narrow, thus greatly reducing the standard deviation. Others show a tendency to "measuring towards whole numbers"; this results in dentate instead of smooth distribution curves. Errors due to optical equipment, photographic recording, colour of the stain, and nature of the light source have all been assessed and so far as possible eliminated. Failure to exclude these sources of error may lead to variation in the mean cell diameter, determined on the same cells, by as much as 1.0 micron. One consolation to the investigator undertaking further work in this field is the conclusion that results of statistical significance are obtainable by measuring only 200 cells in any given case instead of the 500 stipulated by Price Jones.

Using this new and careful technique, Larsen has confirmed the high incidence of macrocytosis in parenchymatous hepatitis. In forty-two of fifty-eight cases a significant increase was observed in the mean cell diameter (M.C.D.) above the normal of 7.79 microns. No increase, however, was found in the mean cell volume, from which it is obvious that the cells are unusually thin. This interesting finding accounts for the difference in incidence of macrocytosis in hepatic disease recorded by different observers, for the results depend upon whether the size of the cell is estimated by the haematocrit or by actual measurement of cell diameters. Of greater interest, however, than the confirmation of increased M.C.D. in hepatitis is the further information obtained about how this occurs. Increase in size could result from peripheral causes in the circulation or central causes in the marrow. Larsen's results prove conclusively that it is the central causes which are of greatest importance. By a modification of a method of statistical analysis introduced by Mogensen[3] he demonstrates that the abnormal frequency-distribution curve of the red cells observed in hepatitis can be resolved into two normal curves—one with a normal M.C.D. of 7.81 microns, the other of 8.56 microns. This

[1] *J. Amer. med. Ass.*, 1926, 87, 470.
[2] *The Distribution of Red Blood Cell Diameters in Liver Diseases*, 1948, Oslo.
[3] *Studies on the Size of the Red Blood Cells, Especially in Some Anaemias*, 1938, Copenhagen.

implies that during an attack of hepatitis an abnormal generation of red cells is produced possessing a larger M.C.D. and a smaller mean corpuscular thickness but with a normal standard deviation.

These characteristics of the red cells in hepatitis are in marked contrast to those found in untreated pernicious anaemia. Analysis of the red-cell distribution curves shows that the blood cell population in the latter condition consists of at least three abnormal components—namely, a left-hand curve of microcytes, a middle curve corresponding to the large cells found in hepatitis, and a right-hand curve consisting of very large cells—as well as one component with normal blood cells. Most unexpected, however, is the finding that in treated cases of pernicious anaemia the distribution curves are still abnormal. The right-hand curve disappears and the left changes gradually to normal; but the middle curve corresponding to the large cells found in hepatitis apparently persists indefinitely. The cell population in pernicious anaemia is therefore quite different from that in liver disease, but becomes remarkably similar to it after treatment with the anti-pernicious anaemia factor in liver. The question why a generation of unusually large thin cells is produced in cases of hepatitis is not answered by Larsen's work. The most obvious explanation is a deficiency of a factor required for the maturation of macronormoblasts to normocytes. Trial of several nutritional factors suggests that nicotinamide is such a factor.

A further and unexpected result of this work is yet another liver-function test. Measurements of M.C.D. and M.C.V. would appear to be of diagnostic value, since an increase of the former without increase of the latter strongly suggests liver-cell damage, and the further changes in these indices are of prognostic significance.

HOW DOES E.C.T. WORK?

The value of electrically induced convulsions in the treatment of depressive psychoses is generally agreed, but how they benefit the patient is uncertain. Explanations and theories are confusingly numerous. For instance, it has been suggested that there may be an incompatibility between convulsions and schizophrenia. Convulsion treatment was originally based on the alleged absence of schizophrenic psychoses among epileptics. Again, E.C.T. may free the patient of unpleasant memories by causing temporary amnesia, or a depressed patient may subconsciously feel he deserves some punishment for his inadequacy and unworthiness, and so by interpreting the E.C.T. as a kind of penance he achieves a morbid satisfaction. Another suggestion is that the brain subjected to an electric shock may produce a substance beneficial to the psychosis. Cerletti[1] named this hypothetical substance "acroagonin" and claimed that extracts of brains of pigs killed by repeated electrically induced convulsions have a therapeutic effect on depressive psychoses which is much greater than the effect of brain extracts from pigs dying under happier circumstances. Attempts to explain the benefits of E.C.T. as the result of an "indirect" action on the autonomic nervous system are not convincing, for the autonomic system is concerned in most physical happenings and its exact part in them is by no means clear.

Whatever the explanation may be, there is general agreement that it may not be the convulsion but some product thereof which benefits the psychotic patient. Obviously it would be a great advantage to secure the improvement without the convulsion, and for this reason Ashby's[2] attempt to demonstrate a hormonal mechanism behind the benefit derived from E.C.T. deserves serious consideration It is now believed that as a result of "stress" the pituitary is stimulated (via the hypothalamus) to produce corticotropic hormones. It would therefore be reasonable to expect a change in adrenocortical activity after the stress of E.C.T. Ashby investigated the excretion of cortical steroids in fourteen psychotic patients submitted to E.C.T. and found that in most cases there was a brisk outpouring of both "sugar-active" cortins and "reducing" cortins during the first few days of treatment, but he could demonstrate no change in the rate of excretion of 17-ketosteroids Great care was taken to avoid errors in this investigation: the collection of urine was checked by creatinine measurements, and the biological assays were first carefully tested for their reliability. Ashby is rightly cautious about the significance of his findings. Granted that E.C.T. alters the excretion of cortical hormones, and also that it improves psychoses, the question remains whether it is the cortical hormones which are the cause of that improvement. Ashby found that the degree of clinical recovery was greatest in the patients whose excretion of adrenal cortical steroids was increased the most, but he admits that the evidence for this was suggestive rather than conclusive. Nevertheless his results are sufficiently convincing to justify further research on similar lines. If E.C.T. works by stimulating the secretion of cortical hormones then it would be reasonable to expect that the direct administration of the necessary hormones would eventually replace the present relatively unpleasant and dangerous method of producing them indirectly.

PRESIDENT-ELECT

Sir Henry Cohen has been appointed President-Elect of the British Medical Association in place of Professor T. P. McMurray, who died on November 16. Professor of Medicine in the University of Liverpool—an office to which he was appointed in 1934 at the early age of 34—Sir Henry Cohen has an international reputation in medicine and bears an authority no less distinguished in the fields of medical education and ethics. He has rendered outstanding service to the Association and the profession as chairman of the Medical Curriculum Committee, which issued its report on "The Training of a Doctor" in 1948, and he is now chairman of the Committee on the Postgraduate Education of General Practitioners, whose report will be published early next year. Since 1946 he has been a Crown representative on the General Medical Council, and he was elected vice-chairman of the Central Health Services Council when it was set up last year. Sir Henry was knighted in the New Year's Honours this year.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

DIAGNOSIS AND TREATMENT OF KETOSIS AND HYPOGLYCAEMIA

BY

WILFRID OAKLEY, M.D., F.R.C.P.

Physician, King's College Hospital Diabetic Department

KETOSIS

The presence of ketone bodies in the urine should be regarded as the initial stage of a process which, if allowed to progress, may result in diabetic coma. Whenever the urine is found to contain much sugar it should also be tested for diacetic acid, as it is in the early preclinical stage of ketosis that treatment is both simple and effective. Rothera's test with ammonium sulphate, sodium nitroprusside, and strong ammonia should be carried out first. If this is strongly positive, Gerhardt's ferric-chloride test should also be made. Rothera's test is by far the more sensitive, and may therefore be strongly positive when diacetic acid is present in concentrations too small to give a positive result with ferric chloride. An appreciation of this difference between the two tests will enable them to be used to give a rough quantitative idea of the intensity of the ketosis. A positive ferric-chloride test should always be regarded as indicating severe ketosis and the necessity for immediate treatment.

Causes of Ketosis

Ketosis is often present in untreated cases of moderately severe and severe diabetes, its presence being unassociated with any other morbid process. In treated diabetics ketosis may be the result of nothing more than inadequate control of the diabetes, but there is often some complicating factor present which causes an increase in the severity of the disease. This may be an acute infection such as gastro-enteritis, hepatitis, pyelitis, tonsillitis, or pneumonia, or a local condition such as an insulin abscess, carbuncle, or a septic condition of the feet, including gangrene.

Gastro-enteritis rightly heads the list, as it is one of the commonest causes of severe ketosis and diabetic coma. This is because it not only aggravates the diabetes but also produces a state of starvation and dehydration, both of which favour the development of diabetic coma. Added to this, in some cases, is the false assumption that inability to retain food constitutes a reason for withholding insulin, the patient having been taught that an injection of insulin must be followed by food. It is important in this connexion to remember that stopping food and insulin in a severe diabetic is one of the quickest and most certain ways of producing ketosis and diabetic coma. For this reason, if a diabetic receiving insulin is unable to eat his normal diet he should always try to take the carbohydrate portion as milk, alone or with a proprietary milk drink, fruit drinks sweetened with glucose or sugar, bread and milk, toast or biscuits, and the usual dose of insulin. If no food can be retained the patient should take half the usual dose of insulin and get in touch with his doctor.

Sulphonamides, penicillin, or other appropriate treatment should be given without delay in cases of infection, and local collections of pus should be drained whenever this may be done without a general anaesthetic. Major operations on patients with severe ketosis should, if possible, be postponed until the diabetic condition has received appropriate emergency treatment (see below).

Symptoms and Signs of Ketosis

These are anorexia, nausea, vomiting, abdominal pain, shortness of breath, and drowsiness. The only signs are a smell of acetone in the breath, furring of the tongue, and sometimes flushing of the face. All these symptoms and signs may be absent in the presence of a strongly positive Rothera's test, but if this warning is ignored they may develop with alarming rapidity, especially when the patient starts vomiting.

Treatment of Ketosis

The discovery of significant ketonuria indicates the need for insulin therapy or (if the patient is already having insulin) an increase in dosage or some other modification of the existing treatment. In untreated diabetics with moderate ketonuria a single dose of protamine-zinc insulin (P.Z.I.) will often correct the condition, even if it does not control the glycosuria. In severe ketosis, particularly if the ferric-chloride test is positive, the best treatment is the use of two injections of soluble insulin (S.I.), as described in last week's *Journal* (p. 1345).

A third dose may be given before the midday meal if heavy ketonuria persists for more than 48 hours. It is impossible to be dogmatic about dosage, but it is usually safe to start with about 16 to 24 units in the morning and a rather smaller dose in the evening.

When the patient is already taking insulin, treatment will depend on the type of insulin used and the arrangement of doses. For patients receiving a single injection of P.Z.I. the addition of some S.I. before breakfast is often effective, but if this fails to relieve the ketosis a second injection of S.I. may be given before the evening meal.

When a mixed injection of S.I. and P.Z.I. is being taken, the dose of S.I. should be increased by 8 to 12 units, and if ketosis persists an evening dose of 12 to 20 units of S.I should also be given.

Ketosis in diabetics receiving two injections of S.I. is relatively easy to treat by increasing the dose of both injections and, if necessary, adding 12 to 20 units of S.I before the midday meal. In all cases care should be taken to see that the daily carbohydrate intake does not fall below 150 g.; if possible, 180 to 200 g. should be given. If the patient is disinclined to eat, the protein and fat portions of the diet may be omitted and the carbohydrate given in the semi-solid or fluid forms described above.

Clinical Ketosis or Pre-coma

When symptoms and signs of ketosis are present the ferric-chloride test will usually be found to be positive, and the condition should be considered as a medical emergency. Treatment consists in giving injections of S.I. and carbohydrate feeds at regular intervals, the following method being both simple and convenient.

The patient's urine is tested four-hourly for sugar (by Benedict's test) and for ketone bodies, and after each test an injection of S.I. is given, the dose depending upon the

amount of sugar present in the urine. Thus, for a red or yellow test the dose may be between 20 and 40 units, for a green test with a yellow deposit 12 to 20 units, and for a blue test 0 to 8 units. Dosage will depend on the height of the blood sugar, if this is known, the severity of the diabetes, and the intensity of the ketosis, and the figures given must therefore be regarded as very approximate. Fluid feeds containing 20 g. of carbohydrate should be given after and midway between the insulin injections, and, if dehydration is at all severe and the patient is not vomiting, additional drinks of water or one-fifth normal saline may be taken with advantage. When there is any tendency for feeds to be vomited the stomach should be washed out with a solution of sodium bicarbonate. If this fails to relieve vomiting, fluids must be given intravenously in the manner described below. Although blood-sugar estimations are not essential in this form of treatment, they add greatly to the ease and speed with which ketosis can be corrected. An initial blood sugar is of particular value in helping to assess insulin dosage. The following chart was devised by R. D. Laurence and is convenient for the treatment of diabetics with severe ketosis or in pre-coma :

INSULIN DOSAGE IN PRE-COMA

Test urine four-hourly for sugar and ketones.
Inject S.I. after each test.

Colour after Benedict's test	Order of dosage of S.I.
Red or yellow	20–40 units
Green, yellow deposit	12–20 ,,
Blue	0–8 ,,

Give fluid feeds containing 20 g. of carbohydrate after and midway between injections.

Diabetic Coma: Diagnosis

As already stated, this condition represents the end stage of a process of progressive ketosis and is therefore never sudden in onset. The history, if available, will always be that of increasing malaise with symptoms of uncontrolled diabetes and ketosis extending over a period of days or, at least, many hours. In addition, there is often a history of intercurrent illness such as gastro-enteritis or some other infective process. On examination, the signs are a combination of those of ketosis and dehydration. The former produces acetopnoea, a heavily furred tongue, and the deep abdominal breathing—so-called air hunger—characteristic of diabetic coma. The latter is responsible for the lowered ocular tension, dry tongue and skin, low or falling blood pressure, rapid pulse, and cold extremities which together constitute the clinical picture of peripheral circulatory failure or shock. The urine is loaded with sugar and acetone bodies, and chlorides are absent or reduced. The blood sugar almost always exceeds 300 mg. per 100 ml. and may be over 1 g. per 100 ml. In making a diagnosis of diabetic coma it should always be remembered that this condition very rarely occurs in elderly obese diabetics, and that cerebrovascular accidents are not uncommon in such patients. In the absence of diagnostic signs in the nervous system diabetic coma can be excluded by finding ketone bodies absent from the urine, or present in traces only.

Treatment of Diabetic Coma

Patients in diabetic coma should be admitted to hospital as quickly as possible, as the longer the treatment is delayed the worse the prognosis. The patient should be put into a warm bed and kept warm with an electric blanket. A

EMERGENCY DIABETIC TREATMENT

Diet and Insulin Control by Urine Tests

DIET. Carbohydrate grammes.

10 g. C. in	Glucose :	⅓ oz.
	Sugar :	2 large lumps
	Orange juice :	4 oz.
	Milk :	7 oz.
	Benger's :	2 level teaspoons.
	Horlick's :	2 heaped ,,
	Ovaltine :	2 very full ,,
	Bread measure =	10 g. C. (⅔ oz.)

INSULIN. Test urine for sugar before each dose, passing catheter if necessary.
Give insulin hourly at

If Benedict's test is :	*Units*	*Marks on Syringe*
Red or yellow = + + + sugar.....		
Green with copper deposit = Trace.....		
Blue = O

general examination should be made, without undue exposure, to exclude any general or local infection, and suitable treatment started without delay.

An injection of 80 to 100 units of S.I. should be given subcutaneously and an intravenous drip set up, if possible into a forearm vein and without cutting down. A catheter specimen of urine should be tested for sugar, ketone bodies, and chlorides, and blood taken for sugar estimation. The stomach should then be washed out with sodium bicarbonate solution. It is convenient to use normal saline for the early treatment of dehydration as it also corrects chloride loss and does not obscure the effect of the initial dose of insulin. The first two litres should be allowed to run in as fast as possible, and if the blood pressure remains very low a third litre may be given in the same way, provided that a careful watch is kept on the bases of the lungs for the onset of pulmonary oedema. Inability to overcome peripheral circulatory failure is the commonest cause of death in diabetic coma, and it is worth while giving 2 pints (1.1 litres) of plasma if saline fails to maintain the blood pressure.

By the time all these things have been done the result of the initial blood-sugar estimation should be known and a decision can be made whether to give more insulin at once or to wait three to four hours for the result of the second blood-sugar test. If the level is very high—over 800 mg. per 100 ml.—a further 80 units or more should be given at once, according to the degree of glycaemia, but for lower levels it is safer to wait and see the effect of the initial dose of insulin. Desperate late cases with a very high blood sugar and an extreme degree of ketosis and dehydration may require many hundreds or even thousands of units of insulin, but they are comparatively rare. The early cases of average severity seldom need more than a few hundred units to remove the ketosis and reduce the blood sugar to a normal level.

There is a tendency at present to give needlessly large and potentially dangerous doses of insulin at very frequent intervals to cases of diabetic coma which could be equally effectively and more safely treated with smaller doses given at intervals of three to four hours. After the second blood-sugar reading has been taken, 4% glucose in 1/5 normal saline should replace normal saline and be given by drip until the patient is conscious and able to take fluids by mouth without vomiting. From this stage onwards the treatment should be the same as that described under "Pre-coma."

Marked tachycardia often persists for several days after the patient has come out of coma, and during this period every care should be taken to throw no unnecessary strain upon the heart. Vitamin B by intramuscular injection in doses of 50 or 100 mg. daily has been advocated, on the assumption that deficiency of this vitamin may be one of the factors responsible for the myocardial weakness.

HYPOGLYCAEMIA

This condition is typically sudden in occurrence, and the patient is well up to the time of onset. The symptoms fall into two main groups. The early symptoms are similar to those produced by an injection of adrenaline, and include pallor, sweating, palpitations, and tremor. The later group are due to failure of oxidation of carbohydrate in nervous tissue, and include higher-centre manifestations such as depression, euphoria, inability to concentrate, deterioration in judgment, and amnesia. There may in addition be central nervous system signs, of which hemiplegia, monoplegia, ataxia, diplopia, and paraesthesiae are the most common. Hunger is a common symptom, and headache, nausea, and even vomiting are sometimes produced by hypoglycaemia, especially when it is due to P.Z.I. A recurrent morning headache relieved by breakfast is always suggestive of P.Z.I. overdosage. Loss of consciousness may be preceded or accompanied by epileptiform fits, and is a late manifestation of hypoglycaemia in all but those rare cases in which the earlier warning symptoms are entirely absent.

Hypoglycaemic coma should always be suspected when a diabetic taking insulin is known to have been in reasonably good health within a few hours of loss of consciousness. A good history will almost always serve to exclude diabetic coma, but a cerebrovascular lesion such as a haemorrhage, embolus, or thrombosis may present more difficulty, especially if the patient is elderly and has arteriosclerosis.

Patients in hypoglycaemic coma are pale, and the skin is moist; ocular tension and blood pressure are unaffected, respiration resembles that of normal sleep, and there is no acetopnoea. Signs in the central nervous system should not be relied upon in diagnosis, for reasons already given, but are more likely to be present in hypoglycaemic than in diabetic coma. The urine may contain sugar if the bladder has not recently been emptied, but if a catheter is passed the next specimen will be found to be sugar-free. Ketone bodies are absent; if they are present as the result of starvation they are insignificant in amount. The diagnosis may be confirmed by estimation of the blood sugar, which is always low and usually less than 60 mg. per 100 ml. Treatment should never be postponed to obtain the result of the blood-sugar estimation. The differential diagnosis of hypoglycaemia and cerebrovascular accident is rendered simple in most cases by the rapid response of the former to correct and adequate treatment, after which any signs in the central nervous system rapidly disappear.

There is a definite relationship between the time of onset of hypoglycaemia and the type and dose of insulin injected. Thus, small or moderate doses of S.I. tend to produce their maximum effect three to five hours after injection, and larger doses (of 40 units or more) six to ten hours after injection or later. In patients receiving morning and evening S.I., hypoglycaemia is therefore most likely to occur before lunch or tea, and again at bedtime or during the early part of the night, according to the size of dose injected. As P.Z.I. acts most strongly when the patient is fasting, it is most likely to produce hypoglycaemia during the late night or early hours of the morning. Mixed injections of S.I. and P.Z.I. may cause hypoglycaemia before the midday meal, in the late afternoon, and during the night. Globin insulin in some patients resembles S.I. and produces hypoglycaemia before the midday meal, while in others reactions are more common in the late afternoon. If globin insulin is given before breakfast it rarely causes hypoglycaemia during the night.

Prevention of Hypoglycaemia

The time relation between insulin and hypoglycaemia already described makes it possible to anticipate its onset and prevent it by the use of so-called buffer carbohydrate feeds. These should consist of 10 to 20 g. of carbohydrate. For a patient receiving S.I. they should be given at about 11 a.m. and 11 p.m. If a single morning injection of P.Z.I. is being used the feeds are taken at bedtime, and with a mixed injection of S.I. and P.Z.I. at 11 a.m. and on retiring.

Treatment of Hypoglycaemia

First give sugar, glucose, biscuits, bread, jam, chocolate, or some other food with a high carbohydrate value. All diabetics treated with insulin should carry sugar or glucose, and a card stating the nature of their complaint, their dosage of insulin, and the name of the hospital, clinic, or doctor they attend. Such a card can be obtained from the Diabetic Association. Treated early, while the patient can swallow, hypoglycaemia responds very quickly, but care should be taken to give enough carbohydrate to prevent relapse. Three or four lumps of sugar is usually a suitable amount to start with, but more should be given if there is not obvious improvement in 10 to 15 minutes. When consciousness has been lost and food can therefore no longer be given safely by mouth, one of the following methods should be used.

1. *Intravenous Glucose.*—This is the ideal method. If a 60% solution is available a sufficient amount of glucose can be given with a 20-ml syringe to bring all but the most advanced cases out of coma.

2. *Subcutaneous Adrenaline.*—The injection of 15 minims (0.9 ml.) of 1 in 1,000 solution of adrenaline will raise the blood sugar, produce a return to consciousness, and permit a solution of sugar to be given by mouth.

3. *Stomach Tube.*—This is a safe and good method, and allows a wide choice of carbohydrate food to be made.

The majority of cases of hypoglycaemia recover spontaneously, but some pass into an irreversible state in which they die, and others recover with permanent damage to the brain. It should always be remembered that frequent attacks of hypoglycaemia resemble persistent or recurrent ketosis in so far as they indicate a state of poor stabilization, but, of the two, they are probably the more dangerous. For this reason, whenever there is any doubt about the cause of unconsciousness in a diabetic taking insulin, always give sugar alone first; if the condition is due to hypoglycaemia recovery will result, and if it is due to any other cause, including diabetic coma, no harm will be done.

INTERNATIONAL CONGRESS OF SURGERY

MEETING AT NEW ORLEANS

The 13th Congress of the International Society of Surgery, held in New Orleans from October 10–15, was attended by about 500 participants from some 45 countries. All Europe, save Germany and Russia, sent delegates. As usual, France, Belgium, Spain, and Italy were well represented.

Throughout the week the weather was trying, for it was both hot and humid, with some heavy showers. The main activities were centred about the Roosevelt Hotel, which was the headquarters and is not far away from what might be called the medical centre. The huge Charity Hospital with its 3,000 beds is situated there, with the medical departments of the Tulane and Louisiana Universities adjoining.

Each delegate was presented with a useful handbook carrying portraits of the president and the venerable Professor Rudolph Matas, who is still hale and hearty at 89. Professor Matas, honorary chairman of the local committee, is beloved as the doyen of the profession in the South and the lodestar of all medical and cultural activities in New Orleans. The list of sponsors of the Congress was interesting and informative, for it included the State of Louisiana, the City of New Orleans, the Harbour Commissioners, International House, the Association of Commerce, the Public Services Incorporation, and the Universities of Tulane and the Louisiana State. Our own public bodies might take notice of the interest in the Congress shown outside the surgical world.

The people were well aware of our presence and took a lively interest in us, while newspaper publicity was keen and profuse, not only in New Orleans but in the United States generally. Everyone was kind and helpful, and imbued with a refreshing degree of civic pride. The city is spread over a large area, the wide boulevard Canal Street leading to an extensive residential district. The open canals, such a striking feature of the original city, are now covered and bordered with trees Drainage and water supply are good, and tropical fevers have been banished since 1905, which year marked the conquest of the "yellow jack" scourge and was a landmark of which the medical faculty has much reason to be proud.

The inaugural function took place on the evening of the first day at 8.30 p.m. This was a formal occasion, graced by the presence of the Hon. Walton Butterworth, an Assistant Secretary of State of the U.S.A.; the Hon. Earl L. Long, Governor of the State of Louisiana; the mayor of the city, the officers of the society; Dr. Sandblom, from Stockholm (representing the delegates); and Lord Webb-Johnson, representing the Royal College of Surgeons.

Dr. Arthur Allen, of Boston, vice-president of the society, presided over the meeting. As there were ten addresses to be made, mainly of a general and semi-political character, it was ten o'clock before Professor Grey Turner, the president of the Congress, was called upon to give his inaugural address. The evening was hot and stuffy, and many in the audience must have already reached the point of weariness, if not exhaustion During the address the president showed by projection pictures of the presidents since the first congress, which was held in Brussels in 1905. His main theme was the training of the surgeon, but in view of the late hour his address had to be considerably curtailed.

Scientific Work

The scientific work began next day. An operating session at Charity Hospital was held from 7.30 a.m. to noon, and the operations were televised to the ballroom of the Roosevelt Hotel. As the galleries for visitors at the hospital provided small accommodation and the floors of the theatres were occupied by many assistants, most delegates had perforce to be content with the television, which was generally agreed to be satisfactory. The screen was 8 ft. by 5 ft. (2.4 by 1.5 m.); the pictures were not in colour, but came out fairly well. Only the immediate operative field could be seen, so that a grasp of the general topography was difficult. There was a running commentary by the operator relayed from the theatres, with some interpolated remarks which were probably not intended to reach the air. The television of other operating sessions was conducted later, when Professors Alton Ochsner, Rives, and others were the operators.

The scientific discussions began on Tuesday afternoon, when Professor Paolucci, of Rome, gave the opening paper on the surgery of the parathyroid. In the discussion Leriche (Paris), Bastos-Ansart (Barcelona), Parsons (New York), Jung and Fontaine (Strasbourg), Mallet-Guy (Lyons), Manzanilla (Mexico), and others took part. Each opener was allowed 30 to 40 minutes and subsequent speakers only five minutes, and it was remarkable how the exertions of the president in the chair managed to keep the speakers pretty well to this schedule Another feature of the Congress was the installation of the headphone transmission, which worked well enough to give great hopes for its complete success in the future. By adjusting the apparatus each member of the audience could elect to listen to the speaker in the language employed or to hear a translation into French or Spanish. If interpreters familiar with technical terms are available the rendering is naturally better.

The next session, on the surgery of the pancreas, was opened auspiciously by Professor Ian Aird. He was assisted by an excellent series of lantern slides with captions in French. He dealt mainly with operative procedure and gave a detailed account of the exposure of the organ. In the discussion most aspects of the subject were dealt with by speakers from Mexico, Sweden, Bulgaria, North Africa, France, and the United States

The meeting on post-operative thrombosis and its sequelae was opened by Alton Ochsner and De Bakey, of New Orleans.

and their remarks were supported by imposing statistics graphically presented on the screen. There was a lively discussion, joined by nearly two dozen, speakers representing surgical experience from many parts of Europe as well as America. Three points came out very clearly: (1) that these conditions were still a serious menace in surgical practice; (2) that early rising after operation had not reduced their incidence; and (3) that no one method of treatment was generally agreed on.

Surgery of the pituitary was discussed by Paul Martin, of Brussels, in a masterly contribution that fully covered the subject. Fontaine, of Strasbourg, spoke on the suprarenal glands. He emphasized the prominent part played by his great master Leriche in the development of this branch of surgery. As he warmed to his task the speaker's eloquence increased, and it was obvious that in concluding after a good innings there was still much that he would have liked to say. An international discussion followed his address, but failed to produce any special pronouncement.

The evening session at 7.30 was on the causes of recurrences after operation on the biliary tract. The opening by Demel, of Vienna, was in German, and was characteristically emphatic and thorough. It was a great effort, a *tour de force*, much appreciated by those who understood or who had read the translation thoughtfully provided by the secretariat. Some latitude to the earlier speakers in the discussion gave an opportunity to Lahey, of Boston, Mirizzi, of Cordoba, Mallet-Guy, of Lyons, and Pribram, of New York, to illustrate their remarks by a fine show of lantern slides.

Later in the discussion the president drew attention to the reproach to surgery provided by the large numbers of cases in which injuries to the bile ducts had followed deliberate surgical intervention. He stated emphatically the necessity for constantly stressing the importance of prophylaxis. Lahey, with his large experience to draw upon, condemned all methods of intubation and was in favour of a deliberate search for the distal part of the duct followed by end-to-end anastomosis. He claimed that this plan gave the best results by far. The session came to an end about 11 o'clock, after a large number of speakers had made their contributions.

Experiment in Discussion

Friday and Saturday mornings were allotted to the presentation of a long series of 15-minute papers by the younger American surgeons. This session had been arranged by the United States branch of the International Society as an experiment and to offset the rather senior tendency in the general discussions. Although the communications were often of great interest, 12 papers before luncheon and 12 afterwards was a strain and a concentrated mental effort for the audience. A great variety of subjects were discussed, many in the fields of purely experimental surgery or advanced physiology. Several members agreed with the president, who, while extolling the experiment, suggested that it would have been more useful if there had been fewer presentations, with time for questions and limited discussion. The scientific meeting came to an end about 3 o'clock on Saturday, and brought a strenuous week to a happy conclusion.

Of the social functions, a harbour trip on the first day was a good way of getting visitors and hosts to meet and to break the ice. The evening reception in honour of the president, held at one of the fine country clubs, was a delightful occasion. The closing banquet at the Roosevelt Hotel on Friday night was also a colourful and enjoyable function. The president occupied the chair, and proposed the health of the President of the United States. There was no formal toast list, but several speakers were called upon to unburden themselves of appropriate messages. There was tremendous applause when Professor Matas came to the loudspeaker. Despite his years the choice was justified, for he spoke audibly and interestingly in English, French, Spanish, and Italian.

At the general assembly of the society, which once again was presided over by the mature Professor Verhoogen, several important decisions were made. It was agreed that, with certain precautions, both German and Japanese surgeons should again be received into the society. A committee was appointed to make suggestions on the reorganization of the journal. It was also decided that the next, the 14th, Congress should be held in Paris in October of 1951, and Professor René Leriche was elected president.

On Wednesday morning visits were made to the two schools of medicine, which occupy adjoining premises and carry out their clinical teaching in the adjoining Charity Hospital. At Tulane a special visit was paid to the Matas Library, where an interesting ceremony was carried out in honour of Professor Matas. The president, Professor Grey Turner, told the company something of the work of Matas and how much he was admired and respected in England. He also spoke of the uses of a medical library, and especially urged his younger listeners to follow the example of the doyen by the study of medical history, not only for its interest but as an assistance to their immediate studies and as a guide to the future. At this ceremony the president was presented with a silver plaque to commemorate the occasion, in honour of Professor Matas.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

ANNIVERSARY CELEBRATIONS

The celebrations of the 350th anniversary of the foundation of the Royal Faculty of Physicians and Surgeons began at the end of November. The origins of the Faculty were described by Professor Alstead in a recent issue of the *Journal* (November 26, p. 1223).

On Wednesday, November 23, the honorary librarian of the Faculty, Dr. Archibald L. Goodall, delivered the Finlayson Memorial Lecture. He, too, recalled the foundation of the Faculty by a grant from King James VI to Maister Peter Lowe in November, 1599. The history of Lowe and Robert Hamilton, the co-founder, he traced in detail, and he described the great events in the life of the Faculty.

On Friday, November 25, the Lord Provost and Corporation of the City gave a civic reception. The president of the Faculty, Dr. W. R. Snodgrass, in thanking the Corporation, reminded them of the long association of the Faculty with the town council, which had promised "to hold, have, concur, fortifie and menteine thame and thair successouris . . . in tyme cuming."

On the Saturday an exhibition in the art galleries was opened by the president. It is devoted to the history of medicine, with special reference to Glasgow and the Royal Faculty. This exhibition will remain on view until January 31, 1950. The Royal Faculty attended divine service in Glasgow Cathedral on Sunday, November 27, and afterwards marched in procession to the tomb of Peter Lowe, where a wreath was laid.

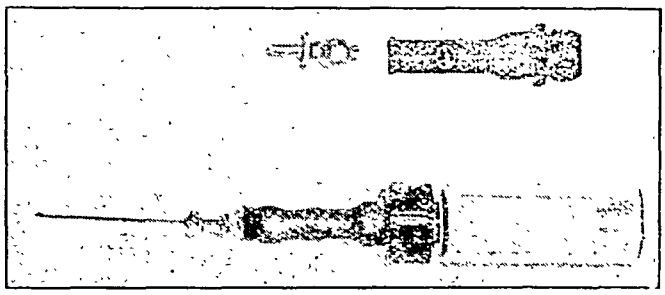
Honorary Fellowships

At a brilliant ceremony on Monday the Faculty conferred its honorary fellowship on Lord Moran, P.R.C.P., Sir Cecil P. G. Wakeley, P.R.C.S., Professor Hilda N. Lloyd, P.R.C.O.G., Dr. W. D. D. Small and Mr. Quarry Wood (presidents of sister corporations), Sir Hector Hetherington (principal of the University), Professor E. P. Cathcart, Professor G. B. Fleming, and Mr. R. Barclay Ness. Congratulatory addresses were presented by the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, the Royal College of Physicians of Edinburgh, and the University of Glasgow. The formal proceedings were followed by a reception.

On Tuesday, November 29, the actual anniversary of the foundation, the commemoration dinner was held. The health of the Royal Faculty was proposed by Sir Hector Hetherington, who made a plea for close co-operation between the Faculty and the University in the training of consultants.

The president, in reply, traced the history of the Faculty and noted that in the last century the State, with good intentions, had made matters more difficult for them. He promised that

in the next 50 years the Faculty would do all in its power to adhere to the principles and spirit of the charter.



Professor Geoffrey B. Fleming proposed the health of the guests, and there were replies from the Lord Provost and Lord Moran. The former hoped that the Faculty would flourish and expand and that all the younger members of the profession would join it. Lord Moran referred to the position of the Royal Corporations as a bulwark against bureaucracy.

Preparations and Appliances

A SIMPLE VACUUM TUBE FOR COLLECTING BLOOD SAMPLES BY VENEPUNCTURE

Dr. R. H. MALONE, of the Regional Blood Transfusion Service in Sheffield, writes: The vacuum tube described here will be found of great value. It consists of a rubber tube ($\frac{3}{16}$ in.—0.48 cm.—bore), and a hollow rubber bung ($\frac{1}{2}$ in.—1.25 cm.—diameter) combined in one piece, a chromium-plated steel ball-bearing ($\frac{1}{4}$ in.—0.6 cm.—diameter), a male adaptor ($\frac{1}{4}$ in. diameter) slotted at the proximal end, and a glass phial of convenient size (approximately 5, 10, or 20 ml.) with $\frac{1}{2}$-in. neck and screw cap.

For sterilization and to produce a vacuum, assemble the unit, tighten the screw cap, and place in the autoclave for half an hour at 120° C. A test-tube 3$\frac{1}{4}$ by $\frac{1}{2}$ in. (8.75 by 1.25 cm.) is inverted on the unit to guard the needle, and on removal of the unit

from the autoclave it is pushed down over the bulge in the rubber tube to form a sterile airtight fitting. Before use inspect the unit to see that the portion of the tube below the ball-bearing is collapsed, indicating a vacuum.

The needle guard is then removed, the needle inserted into the vein, and the rubber tube squeezed at the level of the ball-bearing so that the tubing is pushed slightly on one side. This produces a canal between the inner surface of the tube and the ball-bearing through which the blood is sucked into the vacuum. The needle guard is then replaced.

This unit has the following advantages: (1) A vacuum is automatically produced by sterilizing in the autoclave. (2) Simple inspection shows whether there is a vacuum or not; if the vacuum has been destroyed it can be restored by immersing the unit for 10 minutes in boiling water and then cooling. (3) It can be fitted to any phial with a $\frac{1}{2}$-in. neck and screw cap. (4) It is easily cleaned and reassembled, and can be used many times before the rubber tubing loses its elasticity. (5) Blood samples are taken aseptically. (6) Multiple samples of blood can be taken from the same patient, without removing the needle from the vein, by disconnecting the unit at the adaptor and connecting a new unit. (7) The cost per sample of blood as compared with syringes or "venules" is low.

Any laboratory can assemble its own units once the rubber components have been obtained. The ball-bearings should be chromium-plated or made of stainless steel, since deposits of iron rust cause leakage of air and loss of the vacuum. The adaptor is slotted, because without a slot the ball-bearing, which is forced up by the pressure during autoclaving, seats itself firmly on the end of the adaptor and prevents the escape of air.

The complete unit or the combined rubber tube and bung can be obtained from Messrs. Wm. Freeman and Co., Ltd., Peel Street, Barnsley.

Reports of Societies

MANAGEMENT OF THE GLIOMATA

In the Section of Neurology of the Royal Society of Medicine on December 1, with Mr. JULIAN TAYLOR in the chair, a discussion took place on "Current Trends in the Management of the Gliomata."

Mr. JOE PENNYBACKER discussed in turn the various forms of intracranial gliomata that had come within his experience. Speaking in particular of ependymomata, he said that there was good evidence that these tumours were radio-sensitive, and if surgical measures did not remove them completely it should be possible to deal with any remnants by radiation therapy. He mentioned a case in which an ependymoma had been removed in 1941, the removal being followed by irradiation, and there had been no evidence of return up to the present. The outlook with a medulloblastoma was not favourable, though the literature seemed to show that when such a tumour occurred in adult life the prognosis might be less gloomy. In his series there was only one such case in the favourable group among adults. This patient had remained well for seven years after operation. It seemed possible, however, to approach these tumours with more optimism in the case of adults than in children. Surgery must be accompanied by radiotherapy, and the techniques held out some promise.

Turning to cases of spongioblastoma multiforme, he gave a summary of 89 cases in which a major intervention had been carried out. The operative deaths numbered 14 (16%). Of the survivors, 28 deteriorated within six months, and it was unlikely that any of these were useful survivals; 38 died within 16 months; six within 18–33 months; one at 48 months; and two at 51 months. The procedures undertaken ranged from decompression to complete removal. A rough standard of useful survival was capability for return to work or, in the case of a woman, to household duties. He stressed the unpredictability attending surgery of the gliomas. Surgery alone was powerless in the management of these types of tumours, and the combined efforts of the surgeon and the radiotherapist were essential.

Professor DOROTHY RUSSELL said that her part was to discuss where the pathologist came in in the question of treatment: this, of course, must be in the biopsy diagnosis. The surgeon naturally relied to a great extent upon the accuracy of the pathologist's report; therefore it was useful to discuss the difficulties that arose in the interpretation of the biopsy and the limitations that had to be acknowledged. The main difficulty in a biopsy arose from the admixture of different cytological types and the difference of architecture. On examining certain tumours a curious mingling of highly differentiated types might be found. The pathologist was often forced to use a portmanteau description. The speaker proceeded to review the biopsy material available at her laboratory over a 10-year period: astrocytoma, 119; spongioblastoma multiforme, 129; ependymoma, 30; medulloblastoma, 28; oligodendroglioma, 24. The two first were by far the most numerous types of tumour with which they had to deal. The spongioblastoma multiforme was for the most part derived from the astrocytoma by a process of dedifferentiation or anaplasia. All these cerebral astrocytomas should be viewed with a good deal of suspicion, and it must be insisted that astrocytomas in any part of the brain might behave in the same fashion. Those that occurred as diffuse tumours of the pons and those that occurred in the cerebellum behaved exactly the same. The pontine tumour by reason of its situation, could not be attacked surgically, but in the cerebellum the surgeons could get at the tumour. One met occasionally with cerebellar astrocytomas in which the same changes could be demonstrated. These and many other matters had to be taken into consideration in assessing a biopsy.

Analysis of Results of Treatment

Mr. D. W. C. NORTHFIELD mentioned 58 cases of spongioblastoma multiforme in which a full follow-up had been available. The results were very much as Mr. Pennybacker had

described. Occasionally patients survived for over a year; four had survived for over two years. One patient who was operated on in 1943 was still alive. The tumour in this case was a small one, and the operation was followed by *x*-ray treatment. The patient recovered and returned to work. Four years later there were signs suggestive of recurrence, but these disappeared and no further evidence of deterioration was seen.

The next group consisted of 39 cases of astrocytoma, several of them having long pre-operative histories. In seven of the patients death occurred without any operation or biopsy, and in another seven death followed major craniotomy. The late results appeared unaffected by the operative procedure. There had been a few cases of long survival, up to a maximum of seven useful years. Three patients had lived for over five years; six for over four years. Two patients were still alive. He emphasized the long natural history of some of these tumours.

Of oligodendroglioma there were 15 examples, all subjected to craniotomy. Three died, and the surviving 12 received *x*-ray treatment. One of these was still alive after an apparent total removal eight years ago, but he was handicapped by epilepsy. Another patient had lived seven years after an incomplete removal of the growth.

Only five cases of ependymoma were seen during the period under review, and here the results had been bad. Altogether the treatment of gliomata was a gloomy business. The surgeon was apt to believe, when he removed a compact mass of tumour, that he had taken away a benign growth; but nothing was further from the truth. Astrocytoma was a diffuse infiltrating tumour extending microscopically far beyond the confines of the macroscopically visible growth. The surgeon needed ancillary aid which would inform him at operation whether he had got well beyond the tumour. Any method of showing up tumour tissue would be very helpful. In the surgery of the gliomata, when a tumour happened to be localized the surgeon should endeavour to extirpate it.

An increasing number of gliomata were being treated by radiotherapy. It was difficult to obtain a parallel series of cases with and without irradiation, for no two cases were alike; but they had all seen individual patients in whom, judging by clinical methods, there was no shadow of doubt that irradiation had caused regression. But radiotherapy had its disadvantages and left much to be desired: radio-necrosis was a positive danger.

Sir HUGH CAIRNS said that the general impression to be gathered from the discussion was gloomy, but it seemed important to him to emphasize that the "good" cases came from a group consisting of perhaps twice as many as they had heard about, including cases which had been thought to be gliomata before histological verification was made, and some of these would be benign lesions. With radiographic methods available the needle ought to be able to get right into the region of the tumour almost every time.

No speaker had said very much about the particular situations in the brain in which the tumour was found, but this, of course, very much conditioned the surgery. Mr. Northfield had suggested that they ought to be more radical in the frontal lobe and perhaps in the right occipital lobe. He (Sir Hugh Cairns) did not think there was a case for being more radical, and on the whole he felt that for the more malignant types of glioma the immediate future must be with the radiotherapist. One would like to see some radiotherapist in this country really devote himself to this work. At present the cases were so distributed that no radiotherapist had a really comprehensive experience.

Dr. W. RUSSELL BRAIN said that no doubt modern investigatory methods might miss some tumours of the brain when they were present, but some of these patients who might not have a glioma now were possible candidates for a glioma in the future, and should be followed up, not just written off as cases of cryptogenic epilepsy.

Dr. DENIS WILLIAMS was inclined to think that the electroencephalogram had no value at all in helping towards the exact diagnosis of tumour type. It was only of value in studying what had happened to the brain around the tumour, and the difficulty was that at the time there might be a meningioma, for example, affecting the surrounding brain.

Mr. JULIAN TAYLOR, in winding up the discussion, mentioned the consistency with which the cases seemed to correspond to the clinical picture. When they were looking at cerebral tumours they were not looking at a disease at all, but probably at the results of a disease or of more than one disease; and if that was so, in some of these tumours, as in malignant tumours in other parts of the body, periods of advance, stationary periods, and periods of regression were to be expected.

MEDICAL TREATMENT OF AURAL VERTIGO

A discussion on the medical treatment of aural vertigo took place at a meeting of the Section of Otology of the Royal Society of Medicine on December 2, Mr. GAVIN YOUNG presiding.

Mr. G. H. BATEMAN restricted his paper to the triad of symptoms known as Ménière's disease, which he held to be the vestibular manifestation of a constitutional disorder. He gave the results of a form of treatment used in the ear, nose, and throat department of St. Thomas's Hospital. In this work he had been in collaboration with Dr. J. Kodicek and Mr. L. R. S. Taylor. The treatment which was expounded by Miles Atkinson at the summer meeting of the Section in 1946 was not a perfect one. The patient could not be said to be cured any more than a patient with heart disease could be spoken of as cured when he was controlled by digitalis. Vertigo was caused by a vascular disorder of the small vessels of the labyrinth, resulting in excessive formation of endolymph. The disease might be primary vasodilatation with excessive transudation, or primary vasoconstriction of the arterioles, causing anoxia of the capillaries, which in turn led to excessive transudation through the capillaries when the vasoconstriction passed off. The two groups might be distinguished by a histamine skin test. Cases which gave a negative reaction were treated with nicotinic acid (as a vasodilator). Doses up to 250 mg. t.i.d. had been necessary to relieve the symptoms in some cases. Positive cases were treated by histamine desensitization; 0.05 ml. of a 1:10,000 solution of histamine was injected subcutaneously, and the treatment was continued by doubling the injections on alternate days, increasing the dose by one-half on each occasion. The dose might be increased to about 0.4 ml. of a 1:1,000 solution, but it was rarely possible to maintain the dosage at this rate throughout the course, which lasted about four weeks. By the use of this treatment it had been possible to maintain in active work nine out of ten of the patients who presented themselves.

Mr. L. R. S. TAYLOR added some details of the cases treated at St. Thomas's. Patients who gave a negative reaction to intradermal histamine were given 100 mg. of nicotinic acid three times a day before meals. The patient was told to expect a warm flush 10 minutes later, which would last for 10 minutes. If no flush occurred he was told to chew the tablets before swallowing. After a week he was seen again, and if nothing untoward had occurred 100 mg. t.d.s., a.c., was given for a month. In severe cases intramuscular injections of 50 or 100 mg., once or twice weekly, or even daily at first, might be given. A small maintenance dose must be continued when the symptoms were controlled. Attacks must still be expected, and at the first warning sign—for example, an increase in tinnitus—an intramuscular dose of 50–100 mg. and an extra 100 mg. daily by mouth might be given for a few days. The histamine-positive subjects, after completion of histamine desensitization, had remained well for varying periods up to 18 months, but all had required a second course, and it seemed that a monthly or fortnightly maintenance dose was necessary.

A total of 53 patients had been treated at St. Thomas's, 15 of whom showed a positive histamine skin reaction and 38 a negative one. Vertigo was relieved in 32 and improved in another 20. Tinnitus was relieved in 12 and improved in 22. Both subjective and objective improvement in hearing was noted in 10 cases, the average gain in speech range being about

10 decibels. Headaches, which had been a marked feature in 25 cases, were relieved in 17 and improved in respect of duration and severity in a further six. The cases had been followed up for a period of 18–30 months, and the number of favourable results had far exceeded those following any other non-operative treatment which had been tried.

Mr. I. A. M. MACLEOD gave an account of treatment along similar lines carried out in a series of 50 consecutive cases at Nottingham General Hospital. All the cases were unilateral in type and exhibited the triad of acute vertigo, tinnitus, and deafness in varying severity. Treatment was carried out according to the results obtained from the histamine skin test. The salt used for skin testing and for therapy was histamine acid phosphate.

An initial sensitive reaction was given in 32 cases; 14 were insensitive and the remainder intermediate. The sensitive patients were treated by weekly subcutaneous injections of histamine. The initial dose was 0.1 ml. of 1:10,000 solution of histamine base. This was increased by 0.1 ml. weekly, working up to a concentration of 1:1,000 solution until a reaction was shown by the patient in the form of flushing and headache following injection. This dose was repeated or increased thereafter on three occasions so that four consecutive reactions were produced, and treatment was then stopped. Most patients felt better by the time they had received 0.3 ml. of 1:10,000 solution, as their attacks of vertigo decreased or ceased altogether.

Of the 32 histamine-sensitive cases, 23 had remained free from vertigo since the end of their course (minimum, six months, and maximum, two years eleven months); six cases had relapsed and had further attacks of vertigo, and three cases showed no improvement. The histamine-insensitive group had been treated by nicotinic acid. Initial intramuscular injections of 25–30 mg. were given daily, combined with oral administration of 50–200 mg. Most patients were stabilized on an oral dose only of 50 to 400 mg. daily. Of the 14 cases treated 9 remained free from vertigo; 4 had relapsed, and 1 had not improved. Freedom from vertigo and its accompanying nausea and vomiting had been taken as the criterion of improvement in this series. Improvement in tinnitus and deafness did not take place so frequently.

Mr. C. S. HALLPIKE said that Ménière's disease was in some respects a very satisfactory condition to treat, because the majority of cases did well with little more than a moderate degree of sedation with phenobarbitone, and patients who did not do well on this easy treatment might be referred for the more specialized chemical methods, and again a proportion of them did well. What was unsatisfactory was the rationale of the special treatment, such as histamine therapy. It was sometimes stated that Ménière's disease was an allergic condition, but the manifestations of allergy were multiple, and that did not apply in Ménière's disease. Again, these manifestations of allergy appeared early in life, whereas Ménière's disease appeared later. Finally, there was family history in allergy, which was not seen in Ménière's disease.

With regard to skin tests, they had been told that the cases sensitive to histamine on skin test were the cases in which histamine should be given, and that nicotinic acid should be administered in the insensitive cases. But in his experience, if patients were negative to histamine there was not the slightest reason why histamine should not be given, and vice versa. Histamine and nicotinic acid were chemically quite different, but they had this in common, that they produced an increased vascularity, possibly in the labyrinth, and it did not seem to matter very much which was given. He hoped that more work would be done in investigating the circulation of the fluids in the internal ear.

Mr. I. SIMSON HALL said that each of the various systems of treatment claimed a considerable proportion of successes. The difficulty was to assess the value of each treatment as it was introduced. In an attempt to assess the progress in medical treatment he had studied the medical failures—in other words, the cases referred for operative treatment. In a series of 150 to 200 cases a few years ago he discovered that 20% had been so referred, and in a later series 15%, so that it seemed some advance could be claimed for the new methods.

Mr. GILROY GLASS said that in watching the results, especially those of Mr. Macleod, he had been impressed by the sense of well-being and confidence of the patients. He referred to two cases, alarming at the time but interesting in retrospect. By an error in dispensing a batch of histamine was made up to 1:10 instead of 1:10,000, and two patients received the injection. Both became unconscious, with severe shock, but both recovered. The point of interest was that neither of them had had any vertigo since. Both the patients had been extremely deaf, but on regaining consciousness both had normal hearing, which was maintained in one case for six months and in the other for one month. It was not an experiment to be repeated, but the fact remained that something happened which restored their hearing, at least temporarily.

Mr. TERENCE CAWTHORNE said he had found that, whatever medical treatment was advised, about 50% of patients seemed to be benefited, and if one carried on from one medical treatment to another medical treatment a further 25% might be put in the satisfactory group, leaving about 25% in which more drastic surgical treatment might be required. He had been impressed by the fluctuation of the hearing in hydrops of the labyrinth. One day the hearing would be down, particularly in the dense tones, and another day it would be up.

Mr. H. V. FORSTER mentioned certain compounds which were being tried out in treatment in the United States, and Dr. M. G. GOOD described certain cases of vertigo not dependent on the ear but related to a condition of idiopathic myalgia. Mr. BATEMAN, in reply, said that he did not altogether agree with Mr. Hallpike that most of these patients could be relieved by sedation. He also disagreed with him when he suggested that it did not matter whether the two groups were differentiated by skin-testing or not. If one started therapy without doing a histamine skin test one would be able to predict with great accuracy from the results what the skin test would have shown

OSLER REDIVIVUS

A Year with Osler: 1896–1897. Notes taken at his Clinics in The Johns Hopkins Hospital. By Joseph H. Pratt. (Pp. xxi + 209. $4.) Baltimore: The Johns Hopkins Press. 1949.

This book is an interesting and valuable addition to Osleriana, appropriately published in the centenary year of Osler's birth. It opens with an attractive introduction and preface, but the bulk of the text is a reproduction of notes made over fifty years ago, when the author was a pupil of Osler at the Johns Hopkins Medical School. Osler spoke slowly enough for his statements to be taken down verbatim—"his students cherished his words"—and one of his pupils has now reproduced them for transmission to others.

Such *pietas* is as praiseworthy as the accurate taking-down of some sixty thousand words or more during a single year is remarkable. The would-be reader will ask, Is there value to-day in this detailed, half-century-old record of a clinical teaching session? Will he find it more than an interesting historical document illustrating an era that is now long past, never to return? The answer is, without any doubt, that these notes have been justifiably preserved and published for the benefit of present-day practitioners and teachers of medicine, and that it is impossible to read any page without being stimulated. In particular, the teacher will benefit by the detailed demonstration of a master's way of instructing the young student. But all will learn from the book, and the amount learned will be far from small.

As Dr. Pratt himself writes, "Although these clinical lectures and demonstrations were given fifty years ago, they possess their original freshness in large measure"; and "they show how much can be learned at the bedside by the inquiring mind, the seeing eye, and the trained hand, even without the aid of modern laboratory methods."

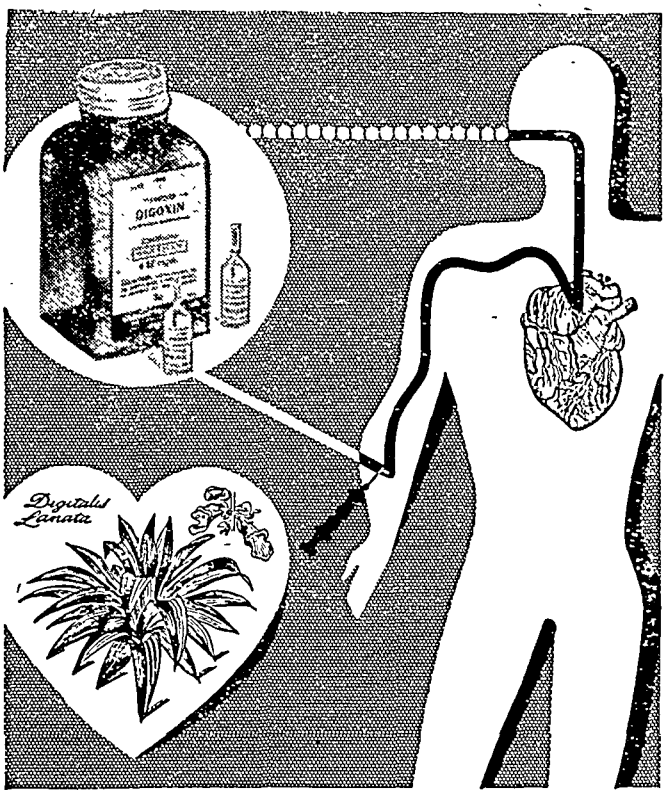
K. I. FRANKLIN.

It's so easy–

with chewing gum

to treat oral infections due to penicillin-sensitive organisms.

When chewed slowly Penicillin Chewing Gum A & H provides an effective concentration of penicillin in the mouth for three to four hours.



It is the preparation of choice in the treatment of *Vincent's infection, tonsillitis, and other infections* within the buccal cavity due to organisms susceptible to penicillin.

PENICILLIN CHEWING GUM A&H

In packets of six pieces, each piece containing 5,000 i.u. penicillin (calcium salt)

SAFETY and CERTAINTY

For initial digitalisation or for maintenance, Digoxin produces the desired result quickly, safely and with certainty. Being a single crystalline glycoside of definite composition and potency, it ensures a degree of accuracy unattainable with digitalis leaf products. Orally, Digoxin is effective in a few hours; intravenously, in a matter of minutes. It is particularly suitable for maintenance in the ambulant patient because the dose may be adjusted precisely, and risk of toxic effects is reduced, 'Tabloid' brand Digoxin, 0·25 mgm., for oral use; 'Wellcome' brand Sterile Alcoholic Solution of Digoxin (for the preparation of Injection of Digoxin).

BURROUGHS WELLCOME & CO. (THE WELLCOME FOUNDATION LTD.) LONDON

'ANAHÆMIN'

The *established* treatment for pernicious and other macrocytic anæmias

EVIDENCE is accumulating that the therapeutic action of liver extract in pernicious anæmia depends upon the presence not only of a primary factor, vitamin B_{12}, but upon the presence also of accessory factors (*J. Clin. Invest.*, 1949, **28**, 791).

For most cases of pernicious anæmia, therefore, whether complicated with subacute combined degeneration of the cord or not, Anahæmin is recognised as the preparation for effective treatment; this is acknowledged by the pre-eminent position held by Anahæmin for more than a decade.

'ANACOBIN'

Solution of PURE crystalline vitamin B_{12}

Occasionally, cases of pernicious anæmia arise which cannot be treated satisfactorily, even with Anahæmin, because of hypersensitivity. For such cases Anacobin is available.

INFANT WELFARE

A considerable amount of work has been carried out recently with a view to lowering the neo-natal and infant mortality rates. As a result, attention has been drawn to the importance of good feeding for the expectant and nursing mother.

The particular efficacy of Marmite as a natural source of B_2 vitamins for inclusion in the ante-natal diet is well proved. Moreover, Marmite is often found to be of special value for infants who are not thriving, and it is particularly indicated for premature and for bottle-fed babies.

MARMITE

yeast extract

contains
Riboflavin (vitamin B_2) 1.5 *mg. per oz.*
Niacin (nicotinic acid) 16.5 *mg. per oz.*

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

Obtainable from chemists and grocers

Special terms for packs for hospitals, welfare centres and schools

Erysipeloid

SIR,—I was interested in the medical memorandum by Dr. R. A. Bush (October 29, p. 964) and I agree that most cases of erysipeloid are penicillin-sensitive, though during the past few months I have seen two cases which have dragged on for a month or so in spite of adequate doses. I do not agree with the statement that the disease is by no means common. I believe it is more correct to say that it is by no means commonly recognized. At a recent examination for a higher surgical diploma I found that only about one candidate in ten was familiar with the condition.

Erysipeloid is more common in certain localities, and is seasonal—June to October being the optimum months. The reddish-purple area on the hand, which follows a prick by a fish-scale or poultry bone, is very typical. Untreated, this intradermal, *not* subcutaneous, inflammation slowly extends over the adjacent palm or fingers and subsides in from four to six weeks, during which period disability results from itching and stiffness. Regional lymph nodes are occasionally enlarged, probably as a result of the initial skin puncture. I have never seen lymphangitis as described by Dr. Bush.

It is important that this disease should be recognized, both from the point of treatment and maltreatment. The majority of cases respond to penicillin but are resistant to sulphonamides, and surgery is contraindicated—in spite of which I have seen two cases which were incised as indolent whitlows. It is interesting to recall that erysipeloid was described as long ago as 1873 by Morrant Baker, who termed it erythema serpens, and it is now commonly referred to as "fish-handler's disease."—I am, etc.,

London, W.1. R. J. MCNEILL LOVE.

SIR,—Mr. Thomas G. Lowden has made several observations on erysipeloid (November 26, p. 1231) and I am prompted to add my comments on this interesting and often undiagnosed condition, since I treated a fairly large number of cases during a period of 18 months at the Royal Northern Hospital. I would agree that the incidence is in the region of 1% of septic hands seen, that the cases vary in severity, and that the diagnosis is of necessity made clinically, as incision is not required and thus no material is available for pathological study.

"Untreated" cases—i.e., those patients who have only attended for treatment after self-medication with poultices, etc., for several weeks—do not resolve readily in spite of penicillin, taking 2–3 weeks further to clear (i.e., as long as 5–6 weeks from the original date of onset). The condition sometimes spreads slowly on to the hand but is often surprisingly stationary. Although the majority of cases respond to penicillin (250,000 units b.d. for seven days), the response is often slow, and there are a number of cases that do not respond at all but tend to linger on for weeks like the "untreated" cases. These may have not come for treatment until the second week, but early cases too may react in this way. Sulphonamides appear to be entirely ineffective, as shown by cases referred by general practitioners who have tried sulphonamides without success, and by personal clinical trial.

The commonest cause appears to be a minor prick with a fish, meat, or rabbit bone, but pricks with a variety of sharp objects have been seen to cause this condition. I have also seen one case which followed a small burn of the finger, there being no history of any obvious source of contamination. The burn had healed before the patient attended hospital, so there was no opportunity of isolating the organism, but clinically the appearance was quite typical. For some reason the disease appears to have a seasonal incidence, and I have noticed a very definite increase in spring and autumn. I have been told that the disease has a definite topographical distribution, and I would be very interested to hear of its incidence in other parts of the country, in order that this contention may be proved or disproved.—I am, etc.,

London, N.12. CYRIL BORODA.

Lymphoid Hyperplasia and Rheumatoid Arthritis

SIR,—Professor Hans Selye (November 19, p. 1129) discusses possible reasons for the favourable modification of "formalin arthritis" by ACTH, "cortisone," the "alarm reaction," and the worsening effect of LAP and DCA. He suggests that the inhibitory action of ACTH and cortisone may be due to their antihistaminic or anti-hyaluronidase properties.

For some time past I have felt that the lymph-gland enlargement found in rheumatoid arthritis (and some cases of "fibrositis") might be an important factor in the production of the disease, rather than secondary to chronic inflammation in the joints as was formerly believed. Selye's paper on the general-adaptation syndrome[1] encouraged me to pursue this hypothesis, particularly as it lent some support for a basic psychogenic aetiology which I believe to be present in many cases. It is known that the synovial cavities of joints are at least in part drained by lymphatics,[2] and Indian ink injected into these spaces may be found very soon in the appropriate lymph nodes. Professor E. W. Walls and I[3] have recently worked on lymphograms obtained by putting "thorotrast" into the synovial cavities of cadavers and moving the joint concerned. This fills the lymph channels and outlines the nodes in a few minutes. My object has been to gain some idea of the normal, to compare with cases which have previously suffered from rheumatoid arthritis. The snags will be obvious, and the scope of the work has been limited to the cadaver owing to our unwillingness to put thorotrast into the joints of living subjects, though this has been done abroad.

Now the photographs (Fig. 7, p. 1133) and description of what happened to the lymph nodes in Professor Selye's experiments have prompted me to put forward tentatively an alternative mechanical theory—that the changes in the joints are due to lymphatic oedema caused by a partial obstruction by lymphoid hyperplasia. In the experiment referred to the rat's glands are small under the influence of ACTH, and the deep staining shows that absorption of ink was rapid. When the glands were hyperplastic from LAP little ink had reached them. Applying the hypothesis to the aetiology of "formalin arthritis," formalin solution is irritant and is probably dealt with subcutaneously by the lymphatic system. It may well be that the system becomes overloaded or damaged, thereby rendering the mild and uncertain "arthritis-producing" property of DCA and LAP more clear-cut. The intensity of local skin reaction could also depend on the speed of removal of formalin.

Finally, Selye's unexpected finding in his rat experiments of main involvement of the ankle-joint, though it was some way from the site of injection, is also capable of explanation by mechanical block of lymphatics. Clinical observation, too, shows that it is the peripheral joints that are mainly affected in rheumatoid arthritis, and perhaps those in which the periarticular tissue is lax are affected most—e.g., proximal interphalangeal points, as opposed to distal interphalangeal. It should not be difficult, given facilities for animal work, to show whether lymphoid hyperplasia can in itself impede lymph drainage.—I am, etc.,

Autotransplantation of Joint Capsule

SIR,—With reference to your annotation (November 26, p. 1221) on this subject, it may be of interest to note that in 1938 we trephined a small controlled series of cases of rheumatoid disease and osteoarthritis at the Royal National Hospital for Rheumatic Diseases, Bath.[1] In the rheumatoid cases no significant improvement was noted, but in those suffering from osteoarthritis there was some relief from the bone pain certain patients experience at night. We felt that some reduction of tension might be the explanation of this improvement in symptoms.—I am, etc.,

Bath. G. D. KERSLEY.

Dermatitis and Stomatitis due to Streptomycin

SIR,—I read with interest the article by Dr. R. A. Pallister on dermatitis and stomatitis during streptomycin treatment (December 3, p. 1271) and wish to state that I have seen a similar syndrome in an imbecile child aged 12 years, who also exhibits tuberose sclerosis and whom I had treated for chronic pyelitis with streptomycin.

I started treatment on October 27, 1949, with one gramme of streptomycin daily in divided doses. On October 28 the temperature dropped to normal and on the 30th the urine was much clearer and temperature was normal. On October 31 the temperature rose to 100° F. (37.8° C.). On November 1 the temperature was 100.4° F. (38° C.). The patient was extremely restless and appeared to be complaining of his throat. On November 2 the temperature was 100.2° F. (37.9° C.). The patient was very restless, scratching his abdomen and trunk. His lips were red, and sore and the mucous membrane of the mouth was inflamed and sore. Streptomycin was continued. On November 3 the patient, when examined, was found to have a mild stomatitis and later in the day developed a well-marked generalized erythematous rash which was marked on face, trunk, and limbs. The palms and soles were clean. On November 4 the rash and stomatitis were more marked, and I diagnosed the condition as due to sensitivity of the patient to streptomycin, a total of 9.25 g. having been given. I stopped the streptomycin treatment on November 4 and ordered calamine lotion to be applied to the rash, which appeared to be extremely itchy, and "benadryl" tablets (50 mg.) to be taken three times a day. The mouth was treated by mouth washes and gentian violet. On November 5 the patient appeared to be slightly better (temperature normal). On November 6 the rash appeared to be fading and the stomatitis was clearing up (temperature still normal). On November 7 the rash was gone and the stomatitis was much better. A vitamin preparation was prescribed. On November 9 the rash and stomatitis had cleared up. Examination of the urine showed the chronic pyelitis to have cleared up also.

The symptoms of this patient were similar to those described by Dr. Pallister as the symptoms of sensitivity to streptomycin —i.e., fever, stomatitis, and rash. In this case the patient reacted to benadryl. I do not think that there is any doubt that the symptoms were due to streptomycin.

I wish to thank Dr. D. J. Rose for his advice and permission to write up this case.

—I am, etc.,

Brockhall, Blackburn, Lancs P. O. O'REILLY.

The G.P. and E.C.T.

SIR,—The correspondence on E.C.T. emphasizes the great difficulty in selecting the right cases for it if one wishes also to reject unsuitable ones. It appears that the criteria to some extent cut across the ordinary diagnostic categories, and it is, of course, inherently likely that they should, since the classification was not designed with E.C.T. in mind. While we may agree in principle that the G.P. can often provide valuable information on the subsequent career of the patient, it will be quite useless if the psychiatrist does not happen to have noted those features of the patient and his environment which are really critical. They may indeed be so subtle as inevitably to escape notice unless specially looked for.

In a case like this, where only a small part of the theoretically available information can, in practice, be extracted, it is necessary to make an intelligent guess. I suggest that a consideration of the nature of a treatment such as E.C.T. *vis-à-vis* the nature of the disease might aid in this direction. How, in short, might such a treatment be expected to benefit such a disorder? In the first place neurosis has, as the statisticians say, many degrees of freedom, while the treatment has very few. We may speak of neurosis as a failure of integration, a maladaptation, a confusion, or many other things. The point here is that every respectable neurosis is a case of not one or two, but a large number of things being wrong more or less independently. To say that they are wrong independently does not conflict with the fact that we can often see how one thing has led to another to make the patient what he is to-day; the environmental story is an integral part of the causal chain, and it might have unfolded far otherwise than it did.

Now E.C.T. in common with suggestion, drugs, psychosurgery, and environmental adjustment cannot of itself put right more than a few things that are independently wrong. The reason is simply that it is not variable in more than a few independent ways. (Of course it might be in theory; there is an enormous number of distinguishable combinations of current, duration, etc., but it will be agreed that in practice the choice is made from quite a small number.) In other words the treatment cannot be exactly matched to the structure of the neurotic personality. Indeed, no known treatment can, although deep analysis may be said to be an attempt, as far as is practicable.

Nevertheless these relatively non-variable procedures do from time to time result in what seems to be permanent cures; and occasionally so-called spontaneous cures occur. The only way we can account for these happy events is on the supposition that the treatment or, in the latter case, a fortunate concatenation of circumstances has, so to say, "started something." The actual cure must be attributed to the psychological environment continuing to "play up" in such a way and for such a time as to allow the psyche to settle down after the disturbance in a new, and better, stable equilibrium. Clearly in some cases it will have to play up in such a manner so specific and unlikely as to be beyond hoping for. Then, or whenever it fails to play up, we must expect the "brittle mask of cheerfulness," as Dr. D. M. O'Connor (October 29, p. 984) aptly calls it, to crack.

The general criterion of selection, therefore, is whether the temporary disturbance will enable the patient to learn what he has to learn from the best obtainable subsequent environment (which may include a psychotherapist). It is a strategical problem in which diagnostic categories can play only a limited, though not unimportant, part and in which no amount of care will ensure success every time.—I am, etc.,

Cambridge. W. E. HICK

SIR,—I feel that Dr. Donald M. O'Connor (October 29, p. 984) has raised an important issue by his letter on E.C.T. and one which should not be dismissed casually. Innumerable papers are published giving statistics of cure by various physical treatments—E.C.T., insulin (modified or deep), prefrontal leucotomy, narco-analysis, and so on—but the degree of cure is assessed by the physician who has given the treatment and not by the G.P. who sees the patient every day. It is obvious that anyone using a therapy for which he has a strong enthusiasm will consciously or unconsciously be prejudiced in its favour. The only person who can give one valuable information is the G.P., and he is never quoted in statistics.

In my opinion physical treatments are useful, but only in a very limited way. For example, E.C.T. will produce excellent results in certain cases, as in menopausal depressions, but this does not mean that all depressions should be put through a "sausage-machine" routine as is so often the case. I know, for instance, of a young man who was homosexual and depressed as a result. He was given E.C.T. without even an inquiry regarding any sort of cause for his condition. In the same way I feel that insulin therapy produces occasional cures, but these are not nearly so frequent as its exponents would have us believe. At almost every one of my out-patient sessions I encounter cases of schizophrenia which have had insulin therapy without any beneficial effect and have even been given E.C.T. (which the statistics of the New York State Hospital show is harmful for such cases). I need not describe the failures from prefrontal leucotomy—they are all too evident. The enthusiasts give us a high rate of cure for such treatments, but what does the G.P. think of them?

There is a strong urge from official bodies that patients should be treated rapidly and inexpensively, so that statistics of cures may be produced and good results may be quoted. I have even heard of one medical superintendent in a mental hospital who discharged all of his doubtful cases just before the time to assess statistics of cure. He could thus show a high recovery rate—although most of those discharged returned the week after. Careful studies in America show that the best results come from clinics where patients are treated as people with anxieties and troubles and not as machines which need a

good jolt to get them going again. I would therefore plead most strongly that we need the observation of the G.P., who does regard his patients as human beings, to correct the mechanistic vision of the enthusiasts for physical regimes.—I am, etc.,

London, W.1. CLIFFORD ALLEN.

SIR,—Dr. Donald M. O'Connor (October 29, p. 984, and December 3, p. 1297) is very right to stress the intense fear and dread expressed by a considerable number of patients. I have frequently discussed this with them when back in their own homes and secure. Most say they cannot say what it is they fear—there is no pain, no unpleasantness, and yet they cannot face it again. Many say they have heard the previous patient cry out and the sound has frozen them with fear—I even had one patient who saw her predecessor being wheeled out unconscious. I have, like Dr. O'Connor, found a curious lack of appreciation of this phenomenon among institutional psychiatrists.

As to sequelae, the patients, the relatives, and many doctors are very distressed at the amnesia and confusion so many show on returning home. In very few cases does it last for more than a few weeks. One of my cases developed a full-blown hemiplegia which cleared up in a week or two. Sometimes there is complaint of backache or soreness of joints (hip, knee, ankle). I think this is why the hysterical type does so badly—they get a displacement of their symptoms, they do not lose them.

In reply to Dr. D. N. Hardcastle (December 3, p. 1297) I think a very great deal of information would be gained by the psychiatrist if the mental hospitals had a really good follow-up team. Here in Bristol, for instance, if a patient has had any form of radium or contact x-ray treatment, one receives a regular and standard form of inquiry year after year. I do not think I have ever received a similar query about a psychiatric case, and only an occasional one on a surgical or medical case.—I am, etc.,

Bristol. J. L. FAULL.

Medical Administrators

SIR,—Dr. John Sleigh (November 19, p. 1180) has properly understood my meaning, which, briefly, is that medical men and women should primarily be engaged in the practice of their profession so as to avoid waste of medical man-power at this critical time. Training for administrative work is far less arduous and time-consuming than it is for medicine, calls for relatively few technical qualifications, and is largely intuitive. A layman can do the work if he has common sense, tact, some knowledge of house planning, essential services, housekeeping, and the ability to get along with other people. By attending the meetings of the medical and lay committees he and they are in touch with all requirements and have technical advice available.

Any well-designed administration with a minimum of staff runs by itself. One such that I took over at short notice and ran for seven weeks was, I believe, improved by the change. The so-called work took me from 9 a.m. to 9.15 a.m., and I attended from 6 p.m. to 6.30 p.m. to receive complaints, look over and sign letters, etc. My round was made between these times. Motto—keep the staff small and have an occasional meeting.

The contrast between the health of the community when I was a student and now, especially among the young, is astonishing. In those days rickets, anaemia, and skin diseases were rife, rheumatic fever and venereal disease common, and undernutrition the rule. The children were pale and wan. To-day, with sun-balconied flats, scientifically adjusted food, cleanliness, better school premises, and better feeding, the children are fine and healthy. All this is primarily due to lay planning with medical and scientific advice and to the prevention of infection.

In former times a doctor with the D.P.H. was regarded as a sort of cross between one who wished to avoid practice and a plumber. Being of a mechanical turn and interested in science, building lay-outs, sewage farms, and the like, I nearly went in for it. To-day the bacteriology alone would be far beyond me.

By all means have medical superintendents, but let them also practise as consultants in their own institutions and do a full day's clinical work. Many do, and sometimes dislike the administrative duties that have been thrust upon them.—I am, etc.,

London, W.1. G. H. COLT.

Use and Abuse of Vitamins

SIR,—Professor L. S. P. Davidson (November 5, p. 1036) points out that frank deficiency diseases are rarely encountered in Great Britain to-day. In this connexion I should like to mention a case of mine, a girl of 18 years, whose skin would not stand sunlight. She was seen by an experienced consultant physician and by a leading dermatologist, neither of whom accepted my diagnosis of pellagra. The only suggestion made as to treatment was to carry a sunshade. In the end she was persuaded to eat ½ oz. (14 g.) of raw yeast daily, and when last seen was quite well.

It may be argued that this is a very unusual case, but most doctors must have come across cases of herpes labialis. This condition arises from nicotinamide deficiency and can be quickly relieved by giving nicotinic acid in suitable doses. Herpes simplex can also be produced at will, for instance, by giving a course of sulphapyridine followed by an artificial pyrexia from T.A.B. vaccine.[1] I will not say anything about surgical incisions failing to heal from lack of vitamin C, as this particular difficulty seems to be getting less troublesome.

The answer seems to be that a frank deficiency to one doctor may be a sealed mystery to another. I well remember being told as a student in the pharmacology class that "cod-liver oil was only useful as a source of calories," and must confess to a certain distrust of academic medicine ever since.—I am, etc.,

Shipley, Yorks. HENRY S. RUSSELL.

Menstrual Histories

SIR,—The importance of accurate information concerning the menstrual functions of women has long been recognized by physicians, surgeons, obstetricians, and gynaecologists alike. The uncertainty and indifference to accuracy exhibited by the average woman (even among the better-educated classes) in describing these functions are proverbial. The time wasted by the medical profession throughout the world in arriving at accurate data when trying to get a menstrual history must be phenomenal.

After 22 years' experience in hospital and private practice of this unsatisfactory state of affairs, I should like to put forward a solution to this problem. For the past six years I have consistently handed to nearly every woman between 15 and 50 years old under my care a card which I devised for the purpose and which I have found invaluable in my work. The headings on the card, which is printed on both sides, are reproduced below.

DATE NAME AGE PARA: SMWSDR 12.

TEL.: ADDRESS MISCARRIAGES: OCCUPATION

Date of ONSET (a.m. or p.m. and Day of Week)	Duration Profuse, Normal, or Scanty	Pain: (Present or Absent and When)	Number of Days Since Previous ONSET	Changes in Health or Routine of Life	Remarks (e.g., Emotional Upsets) and Treatment (if any)

The patient needs only to make an entry approximately once a month on the card, which is designed to last in most cases for one year. When complete it can be returned to the medical adviser to be filed with his records of the case. The ready

and willing co-operation of the average patient in this simple method I have found most gratifying, and the importance of the information thus obtained (with the minimum of effort on the part of the doctor) is great.

The objection might be raised (as it has been in some quarters) that it is undesirable to let women, particularly certain introspective types, pay so much attention to what should be considered a normal physiological function. But my experience over many years is that it does not encourage preoccupation with the "periods" and has no undesirable psychological effect. Details have to be recorded only about once a month, and the card merely takes the place of the private jottings in the patient's diary or calendar.

SMWSDR 12 at the top of the card stands for single, married, widow, separated, divorced, remarried, once, twice, etc.

—I am, etc.,

London, W.5. L. CARLYLE LYON

ACTH and Colchicum in Gout

SIR,—It would seem that the only hope of making wide clinical use of the anti-arthritic effects of "cortisone" and ACTH lies in the development of analogues which would be reasonably easy to manufacture. To this end research to ascertain the chemical mechanism whereby the drugs work is under way.

Unfortunately the rate at which this work can progress is also greatly restricted by shortage of the drugs, especially in Britain. A possible line of approach to the problem utilizing freely available material has occurred to me. According to Selye[1] gout is as much a "disease of adaptation" to stress as arthritis. Might it not be worth while then to investigate the mechanism of the specificity of colchicum against gout? It seems that nothing is known about how this agent produces its effect. In fact, only recently has the chemical structure of its main ingredient, colchicine, been investigated.[2]

When injected into patients with gouty arthritis, ACTH increases uric acid excretion with a concomitant fall in serum uric acid level.[3] Presumably colchicum acts by producing the same effect. Exact knowledge of how colchicum works might therefore provide useful clues to the development of the required analogues.—I am, etc.,

Pruritus Vulvae

SIR,—Professor T. N. A. Jeffcoate in his comprehensive paper on pruritus vulvae (November 26, p. 1196) rightly stresses that the general practitioner, the gynaecologist, and the dermatologist tend to see different aspects of the problem. The dermatologist is mainly concerned with those persistent cases that remain after the elimination of those that are more amenable or due to internal gynaecological conditions. He finds that one simple cause is rarely responsible but that more often these cases result from blends and combinations of the "big seven" of contact irritants, emotional, endocrine, infective, metabolic, and nutritional disorders and skin diseases.

A good history is the *sine qua non* for accurate diagnosis, and an illuminated text, *Qui bene interrogat, bene diagnoscit*, would make a good reminder if suspended over the examination couch. A full psycho-physical assessment is necessary, and the unmasking of one cause must not lead to relaxation of the search for others.

The physical signs may indicate the cause or only reveal the added effects of physical, chemical, or microbic damage, which vary both according to the patient's type of skin reaction and the nature of the irritant. These secondary physical signs include lichenification, excoriation, furunculosis, impetigo, infective dermatitis, and eczematous dermatitis. Infection suggests a greater probability that diabetes may be present, but it also arises from nutritional deficiency or from scratching. Even if psoriasis is the local manifestation it must be borne in mind that this disorder does not usually itch and, further, that its presence in the flexures may show the psoriatic's skin reaction to scratching rather than the cause of the pruritus. For this reason the investigation of psoriasis of the vulva must be on similar lines to other obscure cases of pruritus vulvae.

Physical signs due to nutritional deficiency include seborrhoeic eruptions, dermatitis confined to the labia majora, leucoplakia, and intertriginous (monilial) dermatitis. The latter most commonly occurs with diabetes or pregnancy, and in other cases avitaminosis (usually conditioned) must be considered, because monilia may be found on the skin of many women without pruritus as a harmless skin contaminant. Avitaminosis may arise from achlorhydria, gastro-intestinal disorders, fads in dieting, or from insufficient food in elderly women, possibly edentulous, living alone. Drug intoxications, as from gold and arsenic, can also cause a nutritionally based seborrhoeic type of pruritus vulvae, but the condition is usually more generalized in these circumstances.

The diagnosis of a psychogenic cause must only be made, as with any other diagnosis, on positive evidence and not from the negative basis of absence of obvious material cause. Any of the skin reactions mentioned above due to physical, chemical, and microbic trauma may be present, or there may be no physical signs. These cases are related to disgust for coitus or dread of its consequences, including unwanted pregnancy and venereal disease or, extramaritally, the fear of possible family, financial, social, and moral harm that may result. In any case where a psychogenic basis is suspected it is wise to obtain the help of a psychiatrist both for confirmation of the diagnosis and for treatment.

When Professor Jeffcoate states that psychogenic causes are often merely contributory factors he raises the "egg and chicken" controversy again, because it also happens that the "egg" of psychogenic pruritus only too often hatches out the "chick's" chemical and infective dermatitis and lichenification, which cause aggravation of the pruritus and make it seem to be on superficial inspection related only to a local material cause.

A primarily psychogenic or nutritional pruritus vulvae often comes before the dermatologist in an aggravated and eczematized condition from the use of local analgesic agents (particularly benzocaine derivatives), fungicides, and germicides. These complications may be relieved by bland local treatment, but the underlying cause, if it remains, will still have to be relieved. The use of antiseptic and fungicidal applications is rarely necessary, as the infection is usually secondary. A breakdown of the skin's power of self-disinfection may result, so that in fact by their use the very condition is produced that it was hoped to prevent.

X-ray treatment has a very small part to play. It should never be used on moist, infected lesions but should be reserved for a few cases where chronic eczematization or lichenification creates a vicious circle of friction and aggravation of itching. Vulvectomy is only indicated in some cases of leucoplakia and in Bowen's disease, both of which may cause severe pruritus. In "idiopathic" cases it is as illogical as would be the excision of the tongue for tongue-biting in epilepsy. Nerve-undercutting operations and anaesthetic-injection procedures are equally irrational and are likely to lead to increasing despair when the symptom recurs.—I am, etc.,

BRIAN F. RUSSELL.

Parturition after Pneumonectomy

SIR,—Stimulated by the letter of Mr. F. Kellerman and Dr R. Sauvan Smith (October 1, p. 758) on this subject, I hasten to add another case to the one they have recorded.

A woman aged 29 had been an epileptic since 1942. Early in 1948 she developed a lung abscess on the left side for which pneumonectomy was performed on April 30, 1948. In December, 1948, she was referred to our antenatal clinic and was found to be about two months pregnant. Termination of pregnancy was advised by the chest physician, but was refused by her husband (not on religious grounds). She had previously had two normal confinements in 1946 and 1947, with male infants each weighing 7½ lb. (3.4 kg.). The antenatal period was completely normal, apart from external version being required. Labour began spontaneously on June 20, 1949, and delivery was accomplished easily after three hours in the first stage and twenty minutes in the second stage of labour. The puerperium was uneventful. On August 29, 1949, she was sterilized by vaginal hysterectomy, which is the method of choice in a multipara with a cervical or corporeal lesion such as cervicitis or subinvolution.

As pneumonectomy is a relatively new operation it is likely that there are few women who have undergone a pregnancy subsequently. However, it seems probable that their numbers will increase. While therapeutic abortion can easily be justified in these cases, yet there will be many patients who wish to proceed to term.

The antenatal period appears to be unaffected by pneumonectomy. The course of labour must be watched carefully, any delay in the second stage being terminated by forceps extraction. In multigravida with a history of previous easy labours the outcome is likely to be favourable. In a primigravida, however, with the uncertainties of the length of labour and the patient's reaction, the prognosis must be more guarded. Should there be any complicating obstetrical factor caesarean section would be almost obligatory.

My thanks are due to Mr. A. H. Siddons, who performed the pneumonectomy, and to Mr. C. M. Gwillim, who performed the vaginal hysterectomy, for their advice and assistance in this case.

—I am, etc.,

London, S.W.1. J. L. WRIGHT.

Treatment of Ringworm of the Scalp

SIR,—Dr. K. D. Crow (November 19, p. 1175) indicates that he has completely missed the point of our criticism (October 8, p. 815) of the report on the treatment of scalp ringworm with local applications, by Drs. H. Haber, R. T. Brain, and Mr. J. W. Hadgraft (September 17, p. 626). We endeavoured to draw the attention of practitioners to the fact that *x*-ray epilation is still by far the best treatment for *Microsporon audouini* scalp infections, and that the results of the treatment regime used by Dr. Brain and his colleagues were assessed on an uncontrolled series of six cases. We believed that the superiority of *x*-ray epilation was not sufficiently stressed in their recent article, though reference was made to a previous article[1] on a related experiment, and here the value of *x*-ray therapy was freely admitted. In a subsequent letter (October 29, p. 980) Drs. Brain and Haber kindly acknowledged our criticisms and endorsed the emphasis which we place on the value of *x*-ray epilation.

We do not suggest that the literature confirms our contention that 25% of cases of *M. audouini* infection of the scalp undergo spontaneous cure in less than six months. These were our own figures based on several hundred cases, but it is becoming increasingly apparent that future literature on this important point may well substantiate our claim. For example, Shaffer[2] recently stated that 70% of a random sample of 129 cases from an epidemic in Detroit which involved about 7,000 children were found to be free of infection when subsequently examined three years after the original diagnosis had been made.

We laid stress on the fact that Dr. Brain and his colleagues had only six cases of *M. audouini* scalp infection, yet they included in their trial twenty of *M. felineum* infection. We considered this to be misleading, since spontaneous cure within months is well known to occur in the great majority of cases of the latter infection.

Four cases of contact dermatitis from the total of fourteen cases assessed at the time of writing our last letter is admittedly a very high percentage. We agree that we must have been very unfortunate, but, on the other hand, we felt in duty bound to draw attention to the possibility. We can assure Dr. Crow that they were examples of sensitization dermatitis. We used 4.5% salicylanilide in a carbowax preparation kindly supplied by Imperial Chemical (Pharmaceuticals), Ltd., and essentially the same as that used by Kinnear and Rogers.[3] Dr. Brain and his colleagues mentioned local reactions presumably due to mechanical friction, but they did not mention the possibility of eczematized dermatitis.

With regard to *x*-ray epilation, Dr. Crow states that at many specialized centres there is a wait of sometimes 3–4 months before treatment can be commenced. If this is indeed the case then there exists a most unhappy situation, and it is not surprising that tinea capitis is now epidemic in many areas. On discovering our own epidemic we were quite unable to deal with all the cases which were found, but by borrowing a second *x*-ray therapy unit, and with the whole-hearted co-operation of the county medical officers concerned, we were able eventually to carry out epilations at the rate of ten cases per day. We would like here to acknowledge the help, direct and indirect, which we received from Drs. J. Kinnear and John Rogers when planning our programme.

Dr. Crow admits that the method of treatment advocated by Brain and his colleagues is suitable only when facilities exist for examination under Wood's light and, preferably, for cultures of the organism. But there must be very few such centres nowadays which do not also possess or could not borrow a superficial *x*-ray apparatus. He suggests that local treatment should be employed: (1) in all cases of pre-school age (we prefer *x*-ray epilation for all children of 3 years and over, if necessary under general anaesthesia, and we believe that cases of tinea in children under 2 years of age undergo cure with suitable local treatment in the majority of cases, and that in any event at this particular age they are seldom as likely to be a source of infection as older children); (2) when facilities for *x*-ray epilation are not available within a very short time (we agree here), and especially during epidemics (it is just in these circumstances that *x*-ray epilation is of the greatest possible value); and (3) in all cases of infection with the animal microsporon (we believe that, taking the average total duration of untreated infections as at the most about six months, all cases have to be treated on their merits; usually a quick cure in four weeks with *x*-ray treatment is preferable to a wait of some months involving laborious local therapy, as advocated by Dr. Brain and his colleagues, for in the latter event the children have to have their hair cut very short and kept short throughout treatment).

We repeat our reminder to practitioners that *x*-ray treatment is still the only reasonably certain method of cure, and we believe that great harm can be done by attempting local treatment for *M. audouini* scalp infections in any place other than an investigative centre.—We are, etc.,

Importance of Preventive Medicine

SIR,—It is now many weeks since a leading article in your educational number (September 3, p. 524) proclaimed that "the prospects of a career in public health have never been better." And then a few lines later you wrote, "Financially the rewards . . . will always be less than clinical medicine can offer." In the interim only one or two voices have been raised to query this pronouncement, and I think that the time has therefore come to try to make the profession face the implications which it has so far accepted by remaining silent.

First I ask, Is it the considered opinion of the Association that preventive medicine is of so little importance that its remuneration shall compare unfavourably with that of therapeutic medicine? The triumphs of preventive medicine in Britain in the last century have been in their way at least equal to those of the therapeutic branch. Smallpox, typhus, cholera, enteric, and lastly diphtheria have gone or are going. The wastage of infant life has been reduced by about two-thirds. These achievements are not dramatic in the way that successful therapy may be, but they are no less real on that account. Is preventive medicine therefore of so little importance?

If the answer to my first query is in the affirmative, the second must be squarely faced. Does the medical profession claim a vested interest in sickness? The only justifiable ground for casting aside preventive medicine is that it is ineffective. If it is conceded to be effective then it must be given adequate encouragement of all kinds. If they consider it to be effective but not worth equal financial encouragement it is then a legitimate criticism of the therapeutic branch that they want the public to be ill in order that the doctor's livelihood shall not suffer. If, on the other hand, the profession as a whole agrees with preventive medicine in theory and practice, what are they doing to see that the necessary encouragement is given?

It took a year to wring agreement to negotiate from the local authority associations, and after four further months the machinery for negotiation is not ready. Our colleagues in the Civil Service have the necessary machinery, but apparently it cannot be made to work, and they are as badly off. This is not good enough, and calls for an awakening of the medical conscience of every Division and Branch of the Association as

well as in B.M.A. House. If prompt and effective action is not forthcoming the medical services of the central and local authorities will go where the school dental service has already gone—down the drain. The economic pressure is just as great on the doctor as on the dentist, but the opportunity to transfer from prevention to cure less easy to find.

If the local-authority medical services go the way of their dental counterparts there will be the immediate risk of the return of diphtheria on a substantial scale and also of the reappearance of the other epidemic diseases. As a parting shot I want to ask if any of my general-practitioner friends want to have to cope with an outbreak of smallpox without the help of their local health department.—I am, etc.,

Elgin, Moray. I. C. MONRO.

SIR,—How very refreshing to read of Professor R. H. Parry's frankness on proposing the toast of the guests at the Society of Medical Officers of Health Annual Dinner (*Journal*, December 3, p. 1289). Most of us in the public health service are getting just a little tired of the soft soap and treacle regularly handed out to us by every non-medical functionary in the land from the Minister downwards. Everyone loves us, everyone says we are doing a grand job, everyone is awfully sorry for us —and no one does a thing about our status except, of course, talk about it endlessly.

Week after week we read of practitioners struggling for increased remuneration. Good luck to them. But is it really realized that any practitioner the day after he qualifies is a better financial prospect than the medical officer of health who has a specialist diploma and years of experience behind him before he gets his post as M.O.H. with its attendant pittance?

Why have not the associations of local authorities the boldness to come out into the open and say what is pretty obvious anyway—that they don't want a public health service? Then we could all clear out and let it collapse as ignominiously as the school dental service has done, and the rest of the profession could busy itself in trying to patch up ills which would never occur if preventive medicine offered even reasonable inducements and a living wage for anyone but visionaries and lunatics.

Is it not a little ironical that the very body of medical men who started a public health service in this country should be the only ones to be disregarded when the National Health Service Act came into being? Let us have the answer one way or the other, and soon. We don't ask very much—only to be equated financially with other medical men of comparable experience.—I am, etc.,

Wallingford, Berkshire. HECTOR MACKENZIE-WINTLE.

Dangers of Dicoumarol

SIR,—The new coumarin substance, B.O.E.A., described by Drs. Catherine C. Burt, Helen Payling Wright, and Mirko Kubik (December 3, p. 1250), is clearly a more quickly acting and in some ways a safer anticoagulant than dicoumarol. In view of this article and of the leading article entitled "Dangers of Dicoumarol" (p. 1279), I think three important questions need answer. What is the most effective and safest prothrombin level to aim at? How often is it necessary to estimate the prothrombin level? How dangerous are these anticoagulants?

In the article by Dr. Burt and her colleagues a prothrombin level between 20 and 30% was aimed at because it was thought "generally desirable," but in some cases a level of 40 to 50% of normal, "proved satisfactory for clinical improvement." A number of workers[1–4] have all aimed at a prothrombin level of 10 to 20% of normal in the treatment of thromboses. Peters and his colleagues[5] produced a level of 35 to 50% in their cases and recorded good results. Scott and Lissimore[6] described a case of lymphatic leukaemia with multiple mesenteric thromboses which ceased when the prothrombin level was kept between 60 and 70% of normal by dicoumarol. Treatment was maintained for over three years, prothrombin estimations being made at monthly intervals.

During the last four years I have treated 81 cases of thrombosis by maintaining a prothrombin level of 65 to 75% of normal, and the results have been as good as any of those recorded by the authors quoted above for similar cases. No haemorrhage has been observed. These authors have all recommended daily estimations of prothrombin level, and as their patients were constantly in close proximity to haemorrhage this was certainly essential. On the other hand, when one aims at a level of 65 to 75% of normal, dosage can be adjusted to produce this level and maintain it, using the prothrombin estimation to confirm one's aim rather than as an essential in treatment. Estimations in these cases were never done more often than every five days; in prolonged treatment estimations were done once a month. The prothrombin level never fell below 50% and never rose above 80%. In 24 cases treatment has been continued for at least six months of the year for one to four years.

These cases have all been treated at home, but no case in which liver or renal damage has been found or suspected was given dicoumarol without more frequent prothrombin estimations. Shapiro and his colleagues[7] showed how liver damage increased the response to dicoumarol. Richards and Steggerda[8] demonstrated the continued effect of dicoumarol in rats from which the kidneys had been removed; normally the prothrombin level soon falls.

Dr. Catherine Burt and her co-workers also report that no gross cumulative effect of B.O.E.A. has been observed. Bingham and his colleagues[9] found the same with regard to dicoumarol. After taking 10 g. of dicoumarol in 92 days, a man with thromboangiitis obliterans had normal liver and renal function. My patients who took dicoumarol for six months during each of four successive years similarly showed no ill effect, their white and red cells remaining normal.

It is suggested, therefore, that a prothrombin level of 60 to 75% of normal is adequate for the treatment of most cases of thrombosis; that prothrombin estimations in these circumstances are unnecessary more often than every five days in most cases; that dicoumarol and also B.O.E.A. given for a prolonged time are not harmful in correct dosage.—I am, etc.,

Enteritis Due to Duck Eggs

SIR,—The article by Professor L. P. Garrod and Dr. M. B McIlroy on enteritis due to duck eggs (December 3, p. 1259) raises certain problems of prevention. Is there any conclusive evidence that a duck infected with *Salm. typhi-murium* ever transmits infection to the inside of a freshly laid and undamaged egg?

In the article in question the words, "In hens' eggs contamination is confined to the outer surface of the shell," suggest that this may also be the path of infection in duck eggs, facilitated in the case of duck eggs by the greater porosity of the shell and by the conditions under which a duck may lay its egg. Unlike a hen, a duck as often as not does not lay its egg in a nest but anywhere about the farm. In addition, a duck's droppings are almost invariably liquid, and this liquid faecal matter gets trampled over the egg.

Even under these conditions it is highly improbable that the egg will become infected unless it is left lying out for a matter of days, and it is on dirty farms that this is likely to occur. It is these "found" eggs which may have been lying out for an indefinite period which are probably the cause of human infection.

An egg, be it duck or hen, which has been lying in one position for some days tends to become sided-yolked, and when, as happens to all eggs at packing stations, these eggs are lamped and found to be sided-yolked they should be discarded, although this would entail discarding some fresh eggs.

It should also be borne in mind that most cracked, broken, and stained eggs are, at packing stations, turned into what are known as "liquid eggs" and sent to bakeries and caterers.

hence the greater liability to infection even from a "queen of puddings." Lastly, distribution being as it is, it is unlikely that the two hundred eggs delivered to St. Bartholomew's were less than a month old.—I am, etc.,

Hittisleigh, Devon F. E. GRAHAM-BONNALIE.

Chilblains

SIR,—I read Dr. J. T. Ingram's contribution, concerning chilblains, to the "Refresher Course" (December 3, p. 1284) with increasing interest, for it occurred to me while reading this article that chilblains may eventually be classified as one of the minor and localized diseases of adaptation.[1]

As Dr. Ingram states, "Exposure to cold and damp followed by warmth" is the common precipitating factor for chilblains. Exposure to cold is one of the "alarming stimuli" described by Selye. The psychological and nervous influences mentioned by Dr. Ingram could act via the pituitary and the "endocrinotropic" hormones in the same manner that Selye postulates nervous fatigue acts in the alarm reaction.

Finally, the susceptibility for the development of chilblains at puberty, the menopause, and old age and their virtual non-appearance during pregnancy are very suggestive of an endocrine mechanism. It was indeed the remissions of rheumatoid arthritis during pregnancy and jaundice that led Hench to his brilliant observations concerning cortisone.

It would be interesting to know the incidence of chilblains in rheumatoid subjects as compared with that in normal people, and also whether anyone has yet observed a dramatic resolution of a chilblain in a patient treated with cortisone.—I am, etc.,

London, W.5 M. D. WARREN

Resettlement of the Tuberculous

SIR,—The views of Professor Frederick Heaf on rehabilitation of the tuberculous need no bolstering from me against the oblique attack of Dr. Alice Stewart (December 3, p. 1294). It is, however, disheartening to learn that, emanating from "the city of lost causes," philosophic doubt is being cast on the worth of all our policies and schemes in regard to rehabilitation. Misguided these may be, but their fulfilment is at least practicable and realistic. If, as an alternative to the wise and timely reinstatement of tuberculous persons in industry or office, Dr. Stewart can only offer the suggestion of keeping them permanently "in affluence," then she should withdraw from the industrial Midlands and North along with her impedimenta of mass radiography and morbidity tables.

Will she define "affluence" not in the *O.E.D.* sense but in terms of the needs of a tuberculous wage-earner and his wife and family? The standard rates of pensions, sick-pay, and national assistance provide little more than subsistence. Increases have been granted by (or wrung out of) successive Governments sporadically and lagging in time behind the rise in the cost-of-living index. Does Dr. Stewart really think that in future tuberculous persons will be assisted by the State with more than the wherewithal of bare existence? Pensioning-off, however generously, our tuberculous population will not abate by one jot their infectivity in society and in their homes, clubs, churches, and cinemas. Man works for 44 hours, sleeps through 60 hours, and is at home or mixing gregariously with his fellows for 64 hours each week. There is no evidence that exclusion of the tuberculous (even if it were possible) from all work activity would diminish the total infectivity existing in the community. On the contrary, granted eight hours more leisure daily they might well have more opportunities of sowing infection outside workshop or factory.

Half of the tuberculous population becomes capable and does resume work eventually; the work may require to be modified or altered. One-sixth are dying cases, are aged, or are dependent married women. Only the remainder, consisting of 20,000 to 30,000 chronic active cases of pulmonary tuberculosis, need consideration in our rehabilitation plans. Many of them have good work capacity and tolerance. Most are entering or are already at the stage of full productive life. It would be inhumane to deprive these people of opportunity to work and to treat them as "superannuated" men and women at or before the prime of life.

No one, least of all Professor Heaf, advocates the indiscriminate replacement of the tuberculous in industry. Our young people going straight from school to work-bench, shop, or office, there to work alongside older persons, must be protected at all costs. Dr. Stewart's finding of 7 "open" cases in a boot and shoe factory is not germane to the issue unless she also indicates the size of the population that was surveyed or at risk. She decries our present "industrial schemes." To which does she refer? I would draw her attention to the plans of the Disabled Persons Corporation, which has already set up special "Remploy" factories for the tuberculous and aims at establishing one or more in each region. Hull's factory was the first to be opened in the country. It has operated for nine months, has places for 250 men and women, and 60 men are now working there. I can testify to the increased well-being and morale of men who are now being afforded for the first time the chance to work within their reduced physical capacity. As a reward they take home a wage packet on Fridays, earned by their work and skill, instead of being the passive receptors of their "allowances" at the Post Office on Mondays.

Some of the desiderata enumerated by Dr. Stewart in the earlier part of her letter are surely not impossible to attain. I refer to more adequate housing and improved standard of life for tuberculous and healthy alike. These and other social betterments are the prerogative of none, but are within the rights of all to obtain or possess. I assume that Dr. Stewart's letter was intended to be provocative. If her suggestion that it might be better to superannuate tuberculous men and women as a means of reducing the reservoir of tuberculous infection in this country is seriously advanced, then I trust that this latest "Oxford movement" will die a premature and unhallowed death.—I am, etc.,

Hull ROBERT HARDY

Rh Genotype Tests

SIR,—Dr. Edgar Rentoul (December 3, p. 1300) refers to the production of evidence with regard to the Rh sub-groups as being used in a British court for the first time in a medico-legal case recently heard in a Scottish Sheriff Court. Although Dr. Rentoul does not state the date of the hearing, which has otherwise escaped my attention, I gather it was more recently than June 8, 1949, when I gave such evidence at a magistrate's court. The facts of the case were as follows.

A woman who had previously borne an illegitimate child alleged that as a result of a single act of intercourse following a casual meeting she had become pregnant. The defendant, who admitted the act, alleged that a contraceptive sheath had been used. The probable time of conception corresponded with the admitted intercourse.

It has been my practice to test for all the antigens for which I have been able to obtain antisera in disputed paternity cases which I have investigated, but this was the first occasion on which an Rh sub-group had produced evidence of value. The results of testing in this instance were as follows:

	A	B	C	D	E	c	M	N	S
Baby ..	+	−	++	++	++	++	+	+	−
Mother	+	−	++	++	−	?−	+	+	−
Alleged father	+	−	++	++	−	(+)	−	+	−

The result obtained on the mother's corpuscles with the anti-c serum available was a doubtful negative reading, and a very active anti-c serum was not available at the time. Because of the uncertainty of this result an attempt was not made to genotype the individuals, and the evidence was considered to be unsuitable for medico-legal work. The evidence was accepted by the magistrates and the claim dismissed as not proven.—I am, etc.,

Newcastle-upon-Tyne. T. H. BOON.

POINTS FROM LETTERS

Spoons as a Measure

Dr. E. H. JEANES (Rotherham) writes: I was pleased to see the letter of Dr. J. M. Hamill (November 19, p. 1180) regarding the very important matter of spoon measurements. The misconception about the size of the tablespoon is a very common one and can in certain circumstances lead to most unsatisfactory treatment. The position is confused because textbooks often reiterate the myth that one tablespoon contains half an ounce of fluid, whereas in fact it contains one ounce. Contusion is doubly confounded because the majority of medicine bottles are now not marked in tablespoon doses, and the patient has to measure his own dose. . . . Where bottles have been graduated in tablespoons the proper dose is taken, because the patient relies on these bottle markings, yet let it be noted that these measurements are in fact dessertspoon doses, as can be verified by anyone with the interest to do so. It would not be difficult to find prescriptions in the *National Formulary* which would cause definite harm if twice the prescribed dose were taken regularly. The instructions on tins containing dried milk may be misleading. For instance, an infant weighing 8 lb. is started on artificial feeding and the mother is instructed by a nurse to feed by the directions given on the tin. Since some of the leading dried-milk manufacturers give directions in tablespoons of water to be added, the mother proceeds to make the feed by adding four measures of dried milk to eight tablespoons of water. This is poured from a jug into a feeding bottle and given to the baby. The baby, naturally, can only take half the amount, and the result is underfeeding, since only two measures of dried milk are taken. Of course feeding bottles are marked nowadays, but there still exist certain mothers who rely solely upon their own tablespoons and not on the markings on the feeding bottles. It is unfortunate that the Ministry of Food in its instructions issued with National dried milk has repeated the common fallacy that "two tablespoonfuls of water equal about one ounce." It is, of course, two dessertspoonfuls which equal one ounce.

Death by Hanging

Dr. R. PAKENHAM-WALSH (Lancaster) writes: I was interested to read Dr. F. A. Richards's letter (November 26, p. 1235) suggesting that death by hanging was not as instantaneous as is generally supposed. The same thought occurs to me every time I have the unpleasant duty of executing one of my hens by the process of breaking the neck as near to the occiput as possible. Even when everything goes according to plan the hen gives every appearance of being conscious for a few seconds after the neck has been broken. Its eyes remain open and then gradually close, as though the creature was dying slowly. The subsequent "P.M." always shows a considerable haemorrhage in the region of the break, and it is probably this which causes the head and its owner to become finally dead. On one occasion I was anxious that a special pet hen should not suffer, and I was horrified to find that I had pulled the head right off. Death, however, had been instantaneous, as the head was certainly dead by all appearances, while its owner still remained very much alive.

Fracture of the Olecranon

Dr. L. S. WOOLF (London, N.W.11) writes: Thirty years ago the patient of whom I write, then a man of about 30, fell off a bicycle on to his left elbow. An *x*-ray examination showed that the fractured olecranon was drawn up about 2½ in. (6.25 cm.) from the body of the ulna—i.e., there was a separation of 2½ in. between the olecranon and the body of the ulna. It was decided that mechanical means of bringing the fragment of the olecranon down to join the shaft of the ulna would suffice, and an open operation would thereby be avoided. Straps were applied to the upper arm exerting tension on the triceps, and after a short time it was considered that the olecranon was near enough to the shaft of the ulna to form a fibrous union. This in fact is what took place, and the patient had no functional disturbance in the use of the limb. From time to time there was "rheumatism," but it was only recently that there was much pain in or around the elbow. Because of this an *x*-ray photograph was taken, and this revealed that there is, after thirty years, still no bony union, although function is practically perfect.

Pruritus Vulvae

Dr. H. THISTLETHWAITE (Sedbergh, Yorkshire) writes: In Professor T. N. A. Jeffcoate's learned article on pruritus vulvae (November 26, p. 1196) I find no reference to the application of testosterone ointment. A number of my women patients, whose ages range from 30 to 90 years, have cause to bless this ointment, which was recommended to me in the first case by a gynaecologist and has fully justified itself after other measures have failed lamentably. A single treatment which has given relief to some victims of pruritus vulvae deserves to be more widely known and used.

Obituary

WILLIAM ANDERSON, O.B.E., F.R.C.S.

Mr. William Anderson, senior surgeon to Aberdeen Royal Infirmary, died suddenly on November 29. He was born in Aberdeenshire 63 years ago, of a farming family. In 1904 he entered Aberdeen University, and graduated in 1909 with distinction in his final examinations; he was awarded the gold medals in both medicine and surgery After graduation he held hospital appointments in the Royal Infirmary and the Sick Children's Hospital. He became house-surgeon to the late Sir Henry M. W. Gray, to whose influence and inspiration, like so many of his generation, he owed so much—a debt which he always gladly and thankfully acknowledged. Then followed a period of postgraduate study in Germany in the surgical clinics at Tübingen and Berlin.

In 1913 Anderson was appointed to the honorary staff of the Royal Infirmary as anaesthetist—in those days a recognized stepping-stone. In the first world war he served for some four years in France, at first as a regimental medical officer and later as surgical specialist in charge of the surgical division of No. 12 Stationary Hospital. During the war he acquired a comprehensive experience as a general surgeon, though even at that time his main interests were tending to focus themselves on abdominal and thoracic surgery, and by the end of the war he had established his reputation as one of the most promising younger surgeons of the day. For his services he was mentioned in dispatches and awarded the Order of the British Empire. In 1919 he returned to Aberdeen and was appointed assistant surgeon to the Infirmary, again in the service of Sir Henry Gray, and he also joined the surgical staff of the municipal hospitals. In 1912 he became a Fellow of the Royal College of Surgeons of Edinburgh, and in 1923 of the Royal College of Surgeons of England In 1928 he was appointed examiner in surgical pathology and operative surgery for the diploma of F.R.C.S.Ed He rapidly acquired an extensive surgical practice and a steadily increasing reputation as a clinical teacher.

At the outbreak of the second world war he became surgical director to the Northern and North-Eastern Areas, but it was obvious to his friends that he would not be content for long with a purely civil appointment, for his heart was set on service in the field once again. Early in the war he was appointed consulting surgeon to Scottish and Northern Ireland Commands with the rank of brigadier, an appointment for which he was peculiarly well fitted by his experience in the first world war, his shrewd common sense, and his ability to sum up men and affairs Even on a physique as robust as his the heavy responsibilities and the constant journeying to Ireland and all parts of Scotland must have taken a heavier toll than at first appeared.

At different times Anderson held many other important appointments—he was president of the Association of Surgeons of Great Britain and Ireland from 1941–4; an original member and later president of the Society of Thoracic Surgeons of Great Britain; and inspector of examinations for the General Medical Council. He is survived by his widow, two daughters, and one son, to whom all will extend their sympathy.

A.G.A. writes: By the sudden death of William Anderson Aberdeen medical school has been deprived of the services of

Special announcement!

DEXTRAN—Blood Plasma Substitute—is now available as a Crookes Transfusion Solution under the trade name

INTRADEX

This new blood plasma substitute has the following properties and characteristics:—

1 Sterile, non-pyrogenic, non-toxic and non-diuretic.

2 Possesses colloidal osmotic pressure equivalent to blood plasma.

3 Rapidly metabolised and non-cumulative.

4 Universal compatibility provides an advantage over whole blood.

5 Superior to plasma because it is virus free.

Issued in single 20 oz. Transfusion bottles

Literature on request.

SAUNDERS BOOKS

Berens: THE EYE AND ITS DISEASES

By 92 International Authorities, edited by CONRAD BERENS, M.D., F.A.C.S., 1,092 pp. 436 illustrations.

Arranged in 17 sections—each a monograph in itself, including: Embryology, Anatomy, and Development; Physiology and Physiologic Optics; Refraction and Accommodation; Treatment; Preventive Ophthalmology; Laboratory Diagnosis.

New (2nd) edition, just published. 80/-

Levine and Harvey: CLINICAL AUSCULTATION OF THE HEART

By SAMUEL A. LEVINE, M.D., and W. PROCTOR HARVEY, M.D., 327 pp. 286 illustrations.

"... *those who find auscultation difficult will find it helps them to recognize and interpret the various sounds produced in or near the heart.*"—*The Lancet.*

A new book, just published. 32/6

Friedberg: DISEASES OF THE HEART

By CHARLES K. FRIEDBERG, M.D., of Columbia University, 1,081 pp. Illustrated.

A comprehensive detailed presentation of all the diseases and conditions affecting the heart. Destined to become one of the most referred to books on the subject.

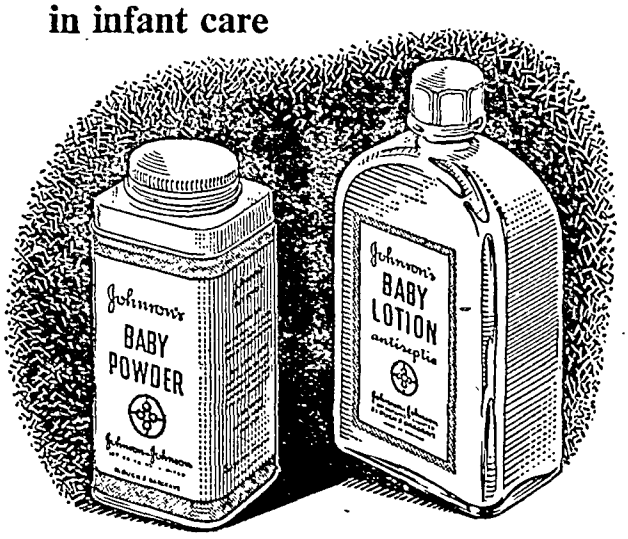
A new book, just published. 57/6

Christopher: GENERAL SURGERY

By 198 eminent contributors, edited by FREDERICK CHRISTOPHER, B.S., M.D., F.A.C.S., 1,550 pp. 1,465 illustrations.

A new (5th) edition of this world-famous textbook on Surgery, thoroughly revised and brought completely up to date. 65/-

Orr: OPERATIONS OF GENERAL SURGERY



By THOMAS G. ORR, M.D., University of Kansas, 890 pp. 1,700 illustrations.

two important aids in infant care

BABY LOTION — *for nappie changing and skin irritation*

BABY POWDER — *for use after every bath*

Johnson's Baby Lotion for the routine care of infants' skin has already received wide medical support. A smooth, white, antiseptic oil-in-water emulsion, it reduces effectively surface bacteria, urine irritation, and other types of rash. Together with Johnson's Baby Powder, these are two important products every mother needs in the care of her baby.

Johnson & Johnson

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED SLOUGH AND GARGRAVE

D.D.T + PYRETHRINS = THE ANSWER*

Recent tests carried out in co-operation with the clinic doctor of an important Metropolitan borough revealed that the *improved* formula SULEO *rendered head lice moribund within 5 minutes and killed all lice present within 15 minutes.*

SULEO HAIR EMULSION is now formulated with D.D.T. *and* Pyrethrins, giving the preparation greatly increased speed of action yet maintaining its original high residual effect which exceeds the incubation period of the nits by some days. A fortnightly application makes infestation virtually impossible.

NON-IRRITANT — NON-TOXIC — EASILY APPLIED — PLEASANTLY PERFUMED — UNDETECTABLE AFTER USE.

SULEO HAIR EMULSION is the best answer yet to the problem of Pediculosis Capitis among adults and juveniles.

MILLBROOK, CHIGWELL, ESSEX

a great surgeon and a great clinical teacher; his colleagues and students, both past and present, have lost a great and loyal friend. He had spent the whole of his professional life in the service of Aberdeen Royal Infirmary, with the exception of some eight years of distinguished military service in the two world wars. I had the privilege of enjoying his friendship and of being closely associated with him since he entered the university as a first-year student in 1904.

In his later years he would often refer to the first world war as one of the most formative periods of his life, and he was proud of having begun his military career as a regimental medical officer. No doubt it was the fruits of that training combined with his native shrewd common sense and his wide clinical experience which made his opinion as a consultant in the second world war of so much value to his patients, his colleagues, and his country.

On his return to Aberdeen in 1919 he threw himself with his accustomed zest and vigour into the work of the hospital—teaching, operating, spending long and arduous days in the out-patient department, performing research at the Rowett Institute, playing hard and working hard. He had an enormous capacity for hard and sustained work, and he could spend hour after hour in the operating theatre without the least sign of fatigue.

The immediate post-war years to him were one of the truest periods of his life. As a teacher he rapidly made a name for himself, and in his teaching he was outstanding for clear, concise, and practical. If in his later life one ventured to suggest to him the advisability of taking things a little bit easier, particularly in giving up his emergency operating and his evening clinics on his receiving days, he would invariably reply that he believed this was one of the most important parts of his teaching, and in this I am sure he had the assent of all who were privileged to attend them. With his students he was approachable; he was friendly and profoundly interested in all that concerned them in their work and play. He was equally happy in presiding at the students' medical society, to which he supplied a constant stream of inspiration, or presiding at the boxing matches, which he thoroughly enjoyed.

Nowhere was his broad and generous humanity seen to better advantage than in his superb handling of patients. With his pawky good humour, his facility in the use of the Doric, he could rapidly put the most nervous patient completely at his ease, and completely win his confidence and gratitude. He remained a general surgeon to the end of his days, although it was perhaps in abdominal surgery that his masterly technique, his resourcefulness, and his courage were seen at their best. He travelled in Europe and America, always eager to keep abreast of the latest developments. At one time he paid particular attention to the developing specialty of neurosurgery and laid the foundations of a neurosurgical unit in Aberdeen. Later he was to return to one of his earlier interests, the development of thoracic surgery, and he must have been one of the first surgeons in Scotland to undertake thoracoplasties, of which he did a great many for the Red Cross sanatoria.

His contributions to literature were comparatively few, for in his busy and active life there was little leisure, and temperamentally he was more interested in the art of surgery and in the individual patient.

Mr. A. Graham Bryce writes: One of those who made a special study of chest surgery while they continued their practice in the general field, Anderson applied himself to his specialty with all the devotion of his honest being. He was an original member of the Society of Thoracic Surgeons of Great Britain and Ireland, and the fortunes of war kept him a member of its executive committee till a few weeks before his death. It was a stubborn obstacle indeed which prevented Anderson from making the long journey from Aberdeen to attend a meeting of the society or of its committee. The opposite of a thruster, he only took part in debate when he really had something to say. It was in the more intimate and informal group round a table in a hotel lounge that his wisdom and wide experience found expression. In committee his constant thought was for the younger men, for whom he was ever ready to efface himself. Of all the qualities which endeared him to his fellows, and for which he will be remembered, his humanity was the most outstanding. There will be a sense of something wanting in any assembly of thoracic surgeons which lacks the cheer of Willie Anderson's presence.

A. M. writes: By the sudden death of William Anderson the medical school of Aberdeen has lost one of its most prominent and useful members, a loss which will be shared by his many friends and patients. His professional achievements are well known, but, as one who was associated with him since his student days, I would like to pay tribute to some of his personal qualities. He set for himself a very high standard of professional work, and gave freely of his time and energy in the care of his hospital patients and in teaching his students. To his colleagues he was always ready to give help when it was needed. Integrity of thought governed his actions, and he was quick and candid in his resentment of anything which he considered unfair or unjust. He had a most generous nature which many of us had occasion to appreciate, and we feel that our world will be the poorer by his loss.

Sir Leonard Rogers writes: The notice of the late Professor C. A. Bentley (December 3, p. 1299) deals fully with his earlier work on malaria and kala-azar. May I add a few lines on his later, and more important, work while Director of Public Health in Bengal on the control of cholera by inoculation. In December, 1923, he issued a circular on anti-cholera inoculation in the Near and Far East, which illustrated its value, and in May, 1927, one entitled "Cholera must be stamped out of Bengal." After five years' struggle—with the support of a new Governor of Bengal, Sir Stanley Jackson, who had made himself acquainted with recent epidemiological work on cholera in India—Bentley obtained sanction for a laboratory to make cholera vaccine at one-eighth the price of that previously supplied, and in 1928 he organized the inoculation of over 2,000,000 people in Bengal—far more than in the whole of the rest of India. Many instances of the rapid suppression of cholera outbreaks in Bengal villages following inoculation first popularized the method in India. It included instances of controls shown by the immediate decline of the disease in inoculated Hindus, but its continuance among Mohammedans, in the same village, who had refused inoculation. It was largely due to the enthusiastic work of Bentley that the long neglect in India of anti-cholera inoculation was gradually overcome—work in which his administrative ability was outstanding and work which will form a permanent memorial to him.

When visiting Greece in August this year Dr. Ludwig Guttmann, clinical director of the Spinal Injuries Centre, Ministry of Pensions Hospital, Stoke Mandeville, delivered a lecture on paraplegia to Army medical officers at Athens at the request of the Greek Minister of War and the Director-General of the Greek Army Medical Services. Dr. Guttmann has now been invited by the medical authorities of the Government of Israel to advise on the organization of a centre for the treatment and rehabilitation of paraplegics. He is spending about three weeks there.

Medical Notes in Parliament

NATIONAL HEALTH SERVICE (AMENDMENT) BILL

The House of Commons considered, on December 9, amendments to the National Health Service (Amendment) Bill accepted by the House of Lords on November 17 (*Journal*, November 26, p. 1239). The Bill was read a third time in the House of Lords on December 2 (December 10, p. 1359).

Mr. BLENKINSOP said the new Clause "A" was inserted to enable the Minister to make regulations adding to the functions of the Medical Practices Committee. Its functions in relation to the distribution of doctors were limited by statute to granting applications by doctors not already on the medical list for inclusion in that list. Where several doctors applied to fill a vacancy it might be held that the Medical Practices Committee was only concerned strictly with applications from outside the area, whereas it had been usual for the Medical Practices Committee to consider applications from wherever they might come and to make its decision on the qualities of the applicants. Experience had shown that an extension of functions might be desirable in one or two other cases. In England and Wales the view was taken that a doctor whose application to employ an assistant was refused by the executive council should have the right of appeal. It seemed to the Ministry that the Medical Practices Committee should have power to determine such appeals. These matters had received the full consideration of the medical profession. Any other similar evidence of the powers and functions of the Medical Practices Committee would also receive the consideration of the medical profession before any changes in regulations were proposed.

Sir HUGH LUCAS-TOOTH said that there should be some statement from the Government that it was not intended to use the wide wording of the amendment to take additional powers for the Medical Practices Committee without giving Parliament an opportunity of considering what those powers should be.

Mr. BEVAN intervened to say there would be regulations which would be laid before Parliament, and the House then agreed to the new Clause.

Charges for Prescriptions

A second new Clause "B" was then debated. It dealt with the recovery of charges in respect of pharmaceutical services:

"Regulations may provide for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such pharmaceutical services, as may be prescribed, and may provide for the remission or repayment of the charges in the case of such persons as may be prescribed."

Mr. BLENKINSOP said the amendment was designed to give statutory authority for the Prime Minister's proposal to make a charge for prescriptions under the National Health Service. The Clause was drafted widely because the exact nature of the arrangements had not been decided. Discussions were proceeding. It had been announced that the charge would not exceed one shilling, and that old-age pensioners would be relieved of the charge, as would ex-Service men who were war pensioners. They would continue to receive free treatment for their war disabilities. The Government had under consideration many representations made by members of the House and others on the detailed working of the scheme.

In the House of Lords it had been suggested that there had been overprescribing by doctors. On that point he could say that there was already a joint committee of the Central and Scottish Health Services Committee to advise Mr. Bevan whether it was desirable and practicable to restrict in any way the prescribing by doctors of medicines of doubtful value and of unnecessarily expensive brands of standard drugs. The Ministry could not make any statement on this till recommendations had been made.

Mr. WALTER ELLIOT said the Opposition did not oppose the amendment, but it should not pass without comment. It would place 19,000,000 people in a worse position than they had been in since July, 1948, and a considerable number of people in a worse position than since 1912, when insured persons were allowed to obtain their prescriptions without this charge. He understood that £10,000,000 would be obtained by this charge. Was that figure still intended? When might the House expect the regulations to be laid? Would they be laid during the prorogation of Parliament?

These regulations would have the force of law as soon as they were laid, and Parliament would require the earliest opportunity to debate them thereafter. He asked whether the sums to be raised by this procedure would obviate the need for a supplementary estimate for the Ministry of Health. Was there any intention to extend the category of hard cases beyond old-age pensioners and ex-Service men who were war pensioners?

Mr. Bevan must, he thought, have determined whether the charge was to be based on each prescription or on each prescription form. The average number of prescriptions was three on two forms. It was desirable to know whether the prescription form or the prescription was to be charged. Was the shilling to be charged on a flat rate or a graded rate? A great number of prescriptions were inexpensive, and on those inexpensive prescriptions the pricing machinery was now in difficulties. He was delighted to think that Mr. Bevan did not accept an increase in prescriptions as an improvement in the health of the country. If small prescriptions were to be priced on a graded figure the difficulty with the chemists would be increased. The Minister should be able by this time to give a lead on these matters.

Mr. FRANK BYERS said he had come to the conclusion that the Lords amendment should be rejected. The House should beware of giving to any Minister powers which could not be examined in detail. What about the difficulties when rural practitioners dispensed their own medicines? What about diabetics who required continuous treatment? He wanted proposals to be laid before the House in a form in which they could be amended in detail. He did not think the scheme would work. If the charge was too high it would cause injustice, and if it was too low it would not remove the abuses.

A Retrograde Step

Dr. SANTO JEGER said he was one of the few medical men in the House who still followed his profession regularly. He regarded the charging for prescriptions as a completely retrograde step. They had encouraged everyone to become health conscious and had said that if people had small ailments they should seek consultation early, but the charge on prescriptions was introduced as a deterrent.

He feared that Parliament would deter the wrong persons from going to the doctor for treatment. A doctor might have to prescribe five or six items for one ailment at one time—for example, for boils. Was a man with a boil to be asked to pay five or six shillings for treatment? Mr. Bevan had talked of cascades of medicines being poured down people's throats. They all knew that a medicine was often given purely as "a mental poultice." It was not always possible for a doctor to eliminate a patient's fears by words. Part of what the doctor had to do was to supply a prescription, a placebo.

Were old-age pensioners who continued in work to be exempted or were they to pay for their prescriptions? Who was to ascertain whether patients were to be exempted? He did not think the doctor would agree to do it, and the chemist should not be required to ask people to produce their birth certificates or to show whether they were drawing the old-age pension. The Minister had received representations from both the British Medical Association and the Socialist Medical Association. He did not think that these two bodies had ever been in agreement before, but they were definitely in agreement on this.

He could show the Minister many ways in which both doctors and patients could avoid this charge. Another, more serious aspect was that any attempt to limit general practitioners to drugs on a standardized list and to prevent them from trying out unestablished drugs would suppress original work.

Mr. BEVAN asked whether Dr. Jeger asserted that, if a committee of responsible members of the medical profession said an ingredient sold under an expensive title was exactly the same as an ingredient sold under a less expensive title, the Ministry

should adopt the idiosyncrasy of a general practitioner and pay the inflated price.

Dr. JEGER agreed that when there were two preparations one should, other things being equal, use the cheaper one.

Mr. BEVAN hoped Dr. Jeger would not pursue the matter further or he might prejudice discussions which were going on. If Dr. Jeger said that in no circumstances could there be an official list of drugs provided by a responsible, authoritative order, he went further than his friends would wish him to go. The amendment under discussion had nothing to do with such a list. It referred to the power to enforce a charge.

Dr. JEGER said that he was prepared to accept what Mr. Bevan had said and not pursue the matter. He declared that in his experience there had been little abuse of the Service. When all possible exceptions had been considered little of the expected £10,000,000 would await collection. If the proposal went through, patent-medicine vendors would find their sales going up by leaps and bounds.

Mr. LINSTEAD, as secretary of the Pharmaceutical Society, thought that the Minister should explore the possibility of "pay as you use" rather than make cuts in the hospital service or hold up the rebuilding of hospitals. But the House should not be asked to go too far in approval of the scheme without knowing in more detail how Mr. Bevan proposed to carry it out. He hoped that the Minister proposed at an early date to bring chemists into the discussions. At present they did not know where they stood. Estimates for the pharmaceutical services were originally £6,000,000 but were now £20,000,000. On those figures the Minister was entitled to see whether something could be saved to the Exchequer. He asked whether a prescription made out for a mother and two children ranked as one or as three. Hundreds of thousands of such prescriptions were written in cases of family sickness. Group prescriptions could be written if there was an epidemic in a school. A doctor might write one for 60 patients. Did that rank for a charge of 1s. or 60s.? His view was that there must be a flat-rate charge, not one graduated according to the value of the medicine. It would be impossible for pricing officers to attempt to make an assessment according to the value of the medicine. The most they could do was to count the forms.

If patients who went to a general practitioner were to be charged, what of the out-patients at hospitals? The last thing they wanted to do was to divert patients from the general practitioner to the out-patient departments of hospitals. There was the problem of the rural doctor. Diabetics had been mentioned, but what about epileptics, people with chronic bronchitis, and the chronic sick generally?

If there was to be a straightforward payment of 1s. when the medicine was handed over the counter the system might possibly work. But if the "pay as you use" principle was justified for the pharmaceutical services it was justified for the dental and ophthalmic and other benefits.

Each According to his Shilling

Mr. SOMERVILLE HASTINGS asked whether the House was going to replace the Socialist principle of "Each according to his need" by "Each according to his shilling." He had found that a little more than half the doctors with whom he had discussed the question had agreed that there had been some abuse. But doctors who said there had been considerable abuse were those who had opposed the scheme from the start. He asked Mr. Bevan whether neurotic people would be deterred by a shilling and robbed of the enjoyment of bad health. One of the people who would be deterred was the poor mother with young children. Doctors were very concerned about the interests of their patients, and in order to save the shilling poor patients might be given enough medicine for a month rather than for a fortnight. More medicine would be ordered rather than less.

The great advantage of a free and universal service was that doctors got hold of illness earlier, and in medicine that a stitch in time saved nine was a truth more important than ever now that so many bactericidal drugs had been introduced. He agreed with Mr. Bevan that some doctors were inclined to order proprietary medicines when an identical cheaper medicine would do as well. The public did not understand how busy the drug houses were in sending their travellers round to doctors. If the Minister gave the doctors lists of equivalent drugs and asked them to supply these to their patients he would save the necessary money and the good name of the scheme.

Mr. SOLLEY contended that the excuse for the order from the Treasury to Mr. Bevan to save £10,000,000—unnecessary resort to doctors and chemists—could not stand investigation. The Minister of Health should have asked himself before putting this burden on the working class whether he could not save the money by taking away some of the profits of the chemical and pharmaceutical manufacturers. The charge must cause great hardship to chronic patients. He would vote against the proposal and would fight on that issue at the General Election.

Administrative Difficulties

Mr. BEVAN sympathized with those Members who had said they did not know how the power which was requested would be used. He himself did not yet know all the answers. The proposal to make a charge up to 1s. created no administrative difficulties. These arose out of the exemptions. It was no economy to transfer a charge from the State to the individual. The proper economy was to introduce a more efficient way of giving the service.

The Government wished to take power to make a charge for the pharmaceutical service alone because this was the part of the scheme where the greatest load had fallen and in which the scheme was inclined not to give the standard of service which the Government required from it. The amendment did not give power to impose a charge. It was to restrict the free service on the pharmaceutical side up to 1s. The National Health Service would pay the cost of a prescription above a shilling. Even with this charge the National Health contributor would have a far wider range of service than was ever available before.

The Government had come to the conclusion that it would be glad to reduce the queues at surgeries and the unnecessary expenditure at chemists' shops. Some of the abuse arose on aspirins, bandages and so forth, costing less than 1s. The proposal had not been received with much indignation because there was awareness of the abuse which had been taking place. The Government must presume that it was not in the interests of the patient to have too many prescriptions. He was not suggesting that the new clause ought to be a permanent feature of the National Health Service. It was put forward as a temporary easement with a residual financial advantage. The figure of £10,000,000 assumed no exemptions, and any exemptions would reduce that amount. The House would have an opportunity of discussing the regulations before they were put into effect. There was evidence already of a reduction in some cases of the burden on the general practitioners.

Mr. HASTINGS asked whether, in view of that reduction in the abuse that he had mentioned, Mr. Bevan would consider that it might be unnecessary for him to introduce these regulations

Mr. BEVAN replied that he was giving consideration to this. He was not anxious to burden himself with a complicated administrative machine if he could achieve the same results by other means.

Dr. SEGAL contended that, if the suggested charge steadily reduced the number of prescriptions, in a few months it might save more than £10,000,000. If the present total of 187,000,000 prescriptions a year could, at the end of twelve months, be reduced by 30%, the need for the imposition of a charge would have vanished.

Mr. PIRATIN contended that no one could give evidence that abuse existed in prescribing.

Mr. SPARKES referred Mr. Piratin to the report of the Estimates Committee on the administration of the National Health Service.

Mr. PIRATIN said he was not surprised to see a united front between the B.M.A. and the Socialist Medical Association. He drew attention to the profits made on medicaments. He said that Glaxo Laboratories, which produced penicillin, made, in 1948, a gross profit of £1,641,000 and a net profit of £660,000. In 1949 the gross profit was £2,605,000 and the net profit £930,000.

There was the case of "dexedrine." It was first introduced by Menley and James at 126s. per 1,000. The tablets were shortly afterwards marketed by Ward Blenkinsop at 31s. per 1,000. In the last few weeks Boots marketed the same preparation at 8s. 6d. per 1,000. Procaine-penicillin was first sold in this country by I.C.I. (Pharmaceuticals) at 44s. a phial. A few weeks later it was sold by Glaxo Laboratories at 32s. As a result of negotiations between the interested firms and Allen and Hanburys the price was ultimately fixed at 36s., which was 4s. above the price of the most efficient manufacturer. There was plenty of scope for cutting down expenditure, apart from this amendment.

On a division the new Clause "B" was accepted by 138 to 5.

Foreign Visitors

On a further new clause added by the Lords Mr. BLENKINSOP said it carried out a pledge given to the House of Commons during the Report Stage of the Bill. It empowered Mr. Bevan to make and recover charges for use made of the National Health Service by persons not ordinarily resident in Great Britain, but Mr. Bevan did not intend a general and wholesale exclusion of foreign visitors from the benefits of the scheme.

Mr. WALTER ELLIOT was glad to see an admission that there had been substance in the case previously put forward by the Opposition.

Dr. BROUGHTON pointed out that the Clause would allow a Minister of Health to make charges on all foreigners using the National Health Service. He said Mr. Bevan was unlikely to make such a regulation. Care must be exercised not to discourage people from other countries coming for medical and surgical treatment if they were prepared to pay for it.

The House then agreed to the new Clause, and consideration of the National Health Service (Amendment) Bill concluded.

Questions about Prescribing

Mr. BEVAN gave an assurance on December 8 that he did not intend to levy charges for prescriptions supplied in hospitals, including those supplied in casualty wards.

Also on December 8 Mr. KENNETH ROBINSON asked the Minister of Health if he knew that many doctors in the National Health Service were prescribing patent medicines under their trade names in cases where similar ingredients, if specified in the prescription, could be dispensed at less cost.

Mr. BLENKINSOP, for Mr. Bevan, answered that a committee appointed by the Central and Scottish Health Services Councils was considering this problem.

Epileptics.—On October 17, 1949, there were 14,370 epileptics in England and Wales registered as disabled persons.

Universities and Colleges

UNIVERSITY OF BRISTOL

The Carey Coombs Memorial Prize for 1949 has been awarded to Dr. I. McD. Stewart for an essay on "The Aetiology of Coronary Thrombosis."

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At the annual meeting of the College held on December 1 Sir David K. Henderson was elected President for the ensuing year and Drs. W. A. Alexander, J. D. S. Cameron, T. Douglas Inch, Ian G. W. Hill, James G. M. Hamilton, and A. Colin P. Campbell were elected members of Council. Dr. Alexander was nominated Vice-President.

CONJOINT BOARD OF IRELAND

The following candidates were duly admitted licentiates in medicine and midwifery on December 2, having passed the final examination in medicine, surgery, and midwifery of the Conjoint Board of Ireland: E. Bradley, P. G. Brady, H. D. Coghlan, Jane J. Connolly, L. A. Cullen, J. C. Dillon, J. A. Doherty, Rita D. Dooley, Elizabeth M. Farrell, J. A. Fitzpatrick, J. B. Gallagher, Rhoda P. Kennedy, M. J. Moran, J. E. Murphy, J. R. Murphy, J. A. MacCarthy, Eva T. MacDonald, J. F. McGuire, O. A. McKee, Mary T. McQuaid, J. F. Napier, D. O. Ndukwe, Maeve S. O'Kelly, C. M. Ongley, W. Quirk, B. FitzG. Regan, I. Rosenthal, Catherine T. Tynan, Mary T. Vass, A. M. Wells.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 26. [No. 47

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949 (a)	(b)	(c)	(d)	(e)	1948 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Annual rate per 1,000 persons living			17·4	20·6				17·4	20·5	
Stillbirths	142	16	31			172	12	23		
Rate per 1,000 total births (including stillborn)			35					26		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

Notifications in the week ended December 3 were: poliomyelitis 141 (176), polio-encephalitis 15 (17). Figures for the previous week are shown in parentheses.

Multiple cases (poliomyelitis and polio-encephalitis) were reported from the following counties: London 16 (24), Berks 3 (3), Buckingham 2 (5), Chester 2 (6), Essex 7 (16), Gloucester 7 (8), Hertford 2 (6), Kent 10 (14), Lancaster 14 (10), Leicester 3 (7), Middlesex 15 (11), Norfolk 4 (12), Nottingham 6 (5), Oxford 2 (1), Southampton 5 (4), Stafford 5 (3), Surrey 6 (6), East Sussex 4 (3), Warwick 6 (7), West Yorks 19 (17), Glamorgan 6 (5).

National Insurance Figures

The Registrar-General has included in his return for the week ended November 26 a new table which will show, each week, the numbers of claims to sickness benefit made under the National Insurance Act during the last four weeks, with weekly averages for each completed month of the year, in each of the 10 standard regions of England and Wales. The weekly averages so far this year have been highest in the month of March in all regions except the London and South-eastern Region, where the highest month was February, and the Eastern Region, where the figures for those two months were the same. The July averages were the lowest in every region. Figures for England and Wales as a whole were as follows:

Weekly Averages Each Month				Week Ended	
Jan. ..	157,800	June ..	83,700	Nov. 22 ..	136,800
Feb. ..	180,100	July ..	78,500	Nov. 15 ..	142,300
Mar. ..	185,400	Aug. ..	88,900	Nov. 8 ..	135,000
Apr. ..	114,400	Sept.	100,900	Nov. 1 ..	121,900
May ..	97,900	Oct. ..	119,200		

Discussion of Table

In *England and Wales* infectious diseases were more prevalent during the week and there were increases in the notifications of scarlet fever 264, measles 168, whooping-cough 44, acute pneumonia 43, dysentery 28, diphtheria 25, cerebrospinal fever 10, and polio-encephalitis 10. There were falls in the incidence of poliomyelitis 43 and typhoid fever 10.

A small rise in the incidence of scarlet fever occurred in most areas; the largest increases were Yorkshire West Riding 53, London 38, and Derbyshire 36. Increases in the notifications of measles were reported in Durham 63 and Surrey 40, with decreases in Staffordshire 39 and Norfolk 34.

The only change of any size in the notifications of whooping-cough was an increase of 33 in Lancashire. Notifications of diphtheria were the largest for 10 months, with increases in Yorkshire West Riding 7, London 6, and Durham 6.

The largest returns for dysentery were: London 25 (Wandsworth 13); Lancashire 19 (Liverpool C.B. 6, Hindley U.D. 6); Yorkshire West Riding 15 (Leeds C.B. 8, Huddersfield C.B. 6); Durham 15; Gloucestershire 10 (Bristol C.B. 10); Glamorganshire 10 (Cardiff C.B. 6).

In *Scotland* there were increases in the notifications of scarlet fever 96, acute primary pneumonia 50, and whooping-cough 20. An increased incidence of scarlet fever was reported from every area. In Glasgow there was an increase of 52 in the notifications of scarlet fever. The rise in the incidence of pneumonia was contributed mainly by the western area. The chief centres of dysentery were Glasgow 47, Edinburgh 10, and Stirling county 10.

In *Eire* increases were reported in the notifications of measles 149 and whooping-cough 37, while a decrease of 14 was recorded for cases of diarrhoea and enteritis. The rise in the incidence of measles was mainly due to an outbreak of 108 cases in Waterford, Dungarvan R.D. No. 1. The increase in the notifications of whooping-cough was mainly due to 29 cases in Waterford, Mullingar R.D. Of the 14 cases of typhoid 11 were notified in Co. Mayo (Castlebar R.D. 6 and Claremorris R.D. 5).

In *Northern Ireland* the chief feature of the returns was a rise of 65 in the notifications of scarlet fever; an increase of 37 cases was reported in Belfast C.B.

Quarterly Returns for Scotland

During the September quarter the birth rate was equivalent to 17.9 per 1,000, and was 1.0 below the average of the third quarters of the five preceding years. The infant mortality rate was 35 per 1,000 registered live births, which was 5 below the rate for the third quarter of 1948 and 14 below the five years' average. The general death rate at 10.1 per 1,000 was 0.4 below the five years' average.

Deaths attributed to the principal epidemic diseases numbered 34 and included 12 from influenza and 15 from whooping-cough. The death rate from respiratory tuberculosis was 51 per 100,000 and from other forms of tuberculosis 8 per 100,000: these figures were 4 and 5, respectively, below the five-year average.

Week Ending December 3

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,755, whooping-cough 981, diphtheria 90, measles 1,654, acute pneumonia 715, cerebrospinal fever 26, acute poliomyelitis 141, acute polio-encephalitis 15, dysentery 159, paratyphoid fever 7, typhoid fever 9, and food-poisoning 121.

Medical News

Nuffield Grant for Cortisone Research

The Nuffield Foundation has made a grant of £5,000 for research on the effects of cortisone in the treatment of rheumatoid arthritis. The research will be carried out under Professor W. T. Astbury, Professor R. E. Tunbridge, and Dr. R. N. Tattersall. As reported last week, the Nuffield Foundation has also made grants to the Universities of Oxford and Cambridge for work on cortisone and allied substances.

Heberden Society Dinner

The annual dinner of the Heberden Society was held at the Royal College of Surgeons on December 9, Dr. W. S. C. Copeman being in the chair. After the loyal toasts had been honoured, Dr. R. M. Mason, in proposing the health of the guests, welcomed Lord Webb-Johnson on his return from the U.S.A. and Canada, and the Heberden orator, Professor F. Wood Jones, F.R.S., who was later presented with the Heberden Medal. Lord Lucas, in replying for the guests, told a cautionary tale about medicine and politics. In proposing the health of the society Lord Webb-Johnson praised Heberden as one of the great clinicians in medical history. Referring to developments of the past decades Lord Webb-Johnson remarked that he had lived long enough to see James Mackenzie lay the foundations of cardiology. In response Dr. Copeman said the medical profession was much indebted to Lord Webb-Johnson for his interest in, and support of those working on, the rheumatic infections. He was glad to be able to say that Lord Webb-Johnson had accepted honorary membership of the society.

Bulgaria Leaves WHO

Bulgaria has decided to leave the World Health Organization. It has stated in a letter to WHO that the practical results obtained by WHO "appear completely insufficient, particularly in the field of international health aid." Soviet Russia, the Ukraine, and Byelorussia withdrew from WHO last February (*Journal*, February 26, p. 375).

Visits to North America

It is hoped that any medical men and women who intend to visit North America will inform the Secretary of the B.M.A. so that information of such visits may be forwarded to the Canadian Medical Association, which is anxious to be of help to doctors from the United Kingdom visiting North America.

Fulbright Travel Grants

The United States Educational Commission in the United Kingdom announces that, under the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and Colonies to go to America for an academic or educational purpose, such as study, research, lecturing, or for other educational activities. Applicants must possess a guarantee of financial support in dollars in America for the proposed period of their stay. Undergraduate and postgraduate students must show proof of admission to an American institution of higher learning. All applicants must be affiliated with such an institution. Applications may be made by candidates who have not yet concluded these financial and institutional arrangements, and in certain rare cases of exceptional merit the commission will try to help obtain dollar support or institutional connexion for those candidates who have not been able themselves to complete these arrangements. Preference will be given to candidates who intend to stay nine months or more, but applications for shorter periods from well-qualified persons who cannot be spared from their present activities for so long will be accepted. Grants cannot be given for attendance at conferences alone. The travel grants are available for travel to America between June 1, 1950, and May 31, 1951. Those wishing to apply should write immediately to the United States Educational Commission in the United Kingdom, 55, Upper Brook Street, London, W.1, requesting a preliminary application card. After return of this completed card the appropriate further forms will be sent to applicants at a later date.

West of England and Wales Society of Dermatology

The inaugural meeting of the West of England and Wales Society of Dermatology was held at Bristol on Friday, October 28. Dr. Clifford D. Evans took the chair. It was decided to hold three clinical meetings each year. One will be held at Bristol in the fourth week of October, one in Wales in the fourth week of January, and one in Gloucester, Plymouth, or Exeter in the fourth week of April. The meeting will be on a Saturday morning and will take the form of a clinical demonstration and discussion followed by lunch. Dr. Robert P. Warin was elected secretary.

Dr. J. McK. A. Lowson

The Sultan of Johore has conferred the decoration of Insignia of the Order of the Crown of Johore upon Dr. J. McK. A. Lowson, Principal Medical Officer, Johore, in recognition of valuable services rendered by him.

A Sixtieth Birthday

The Scandinavian journal, *Acta Tuberculosea Scandinavica*, has recently published a *Supplement* (1949, No. 21) in celebration of Professor Arvid Wallgren's sixtieth birthday. Professor Wallgren, who was for 20 years senior physician at the Children's Hospital, Göteborg, is now professor of child health at the Caroline Institute in Stockholm. The list of his publications contains the titles of 229 papers and books, many on the subject of tuberculosis. The special supplement of *Acta Tuberculosea Scandinavica* contains a number of interesting papers, mostly on the subject of tuberculosis, by Professor Wallgren's Scandinavian colleagues.

Visitors from the U.S.A.

Dr. Harold S. Diehl, dean of the Minnesota School of Medicine, and Dr. L. W. Chandler, dean of the Faculty of Medicine, Stanford University, San Francisco, were guests at a reception held at the Royal Society of Medicine on December 6. They are visiting this country in order to study medical education and its relation to the National Health Service, and they will report their findings to the Council on Medical Education and Hospitals of the American Medical Association. Dr. Diehl and Dr. Chandler hope to return to this country in three or four years' time in order to find out what effect the National Health Service has had on medical education in the intervening period.

COMING EVENTS

Conference on Cardiovascular Diseases

A national conference on cardiovascular diseases will be held in Washington from January 18 to 20, 1950, under the joint sponsorship of the American Heart Association and the National Heart Institute of the U.S. Public Health Service. Dr. H. M. Marvin and Dr. C. J. Van Slyke, co-chairmen of the conference, have said in a published statement: "This conference we hope will provide the guide-posts for a comprehensive and concrete programme of action to correlate an all-out national attack on the heart disease problem."

Oxford Graduates' Medical Club

The 100th dinner of the Oxford Graduates' Medical Club will be held at the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Friday, January 27, 1950, at 7 p.m. for 7.30 p.m., when the chair will be taken by Dr. C. M. Hinds Howell. Dinner jackets will be worn. Tickets may be obtained from Mr. E. G. Tuckwell, F.R.C.S., 73, Harley Street, London, W.1, price 26s. each. Cheques should be made payable to the Oxford Graduates' Medical Club and should reach Mr. Tuckwell before January 13, 1950.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At University New Buildings (Anatomy Lecture Theatre), Edinburgh, December 20, 5 p.m., "*Common Diagnostic Problems in Renal Disease*," by Professor Clifford Wilson.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—December 20, 5 p.m., "*The Treatment of Varicose Conditions of the Lower Limb*," by Mr. A. K. Monro.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—December 20, 3.45 p.m., "*The Larynx*," Arnott Demonstration by Mr. R. J. Last.

APPOINTMENTS

T. P. Mann, M.D., M.R.C.P., D.C.H., has been appointed Assistant to the Professor of Child Health at the Institute of Child Health, University of London, from November 1, 1949.

Dr. Mann will work in the Newborn Baby Department at the Postgraduate Medical School of London, Ducane Road, Hammersmith. He qualified at St. Mary's Hospital in 1941, and after serving as surgeon lieutenant in the R.N.V.R during the war was medical registrar at the Postgraduate Medical School.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—*Consultant Ear, Nose, and Throat Surgeon in Peterborough Area*, A. A. Finlayson, F.R.C.S. *Consultant Radiologist in King's Lynn Area*, Group Captain G. E. Church, M.B., Ch.B., D.M.R., D.M.R.E., R.A.F.

HINDE, R. T., F.R.C.S., Assistant Ear, Nose, and Throat Surgeon, Exeter Clinical Area, South-Western Regional Hospital Board.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Burslem.—On November 30, 1949, at the City Hospital, Chester, to Kathleen (née Griffiths), wife of R. W Burslem, M.D., M.R.C.O.G., a son.

Harris.—On November 11, 1949, at Nairobi, Kenya, East Africa, to Dr. L. B Mary Harris (née Watch), wife of Norman Francis Harris, a son.

Heanley.—On November 26, 1949, to Molly, wife of Charles Laurence Heanley, F.R.C.S., a third son.

Hughes.—On December 3, 1949, at Klinik Hirslanden, Zurich, Switzerland, to Joy (née Laxton), wife of Dr D. R. Hughes, a son—Christopher Dennis.

Tarnesby (formerly Tarnowski).—On November 28, 1949, at 6, Downside Crescent, Hampstead, London, N.W., to Eleanor (née Ettlinger), L.M.S.S.A. and Herman P. Tarnesby, M.B., B.S., D.R.C.O.G., a daughter—Ruth Marie Bettina Tamara.

DEATHS

Braterman.—On December 3, 1949, at 267, Ealing Road, Wembley, Middlesex Harry Lewis Braterman, M.R.C.S., L.R.C.P., aged 43.

Gavin.—On December 4, 1949, at his home, William Christopher Gavin M.B., B.Ch.

Jones.—On December 3, 1949, at Northgate, Russell Road, Rhyl, Flintshire Edward Hughes Jones, M.D., J.P., aged 84.

Jones.—On December 3, 1949, at 1, Grasmere Avenue, Whitefield, Manchester John Grant Jones, M.D., late of Birnie, Elgin, Moray, aged 77.

McDonald.—On December 6, 1949, at Belford Villa, Belford, Northumberland James McDonald, M.D., J.P., aged 82.

MacFaul.—On December 7, 1949, at his residence, Claremont, St. Helens Road Leigh, Lancs. Alexander MacFaul, M.B., B.Ch.

McKinstry.—On December 7, 1949, William Kilbourn McKinstry, M.R.C.S., L.R.C.P., aged 50

Munro.—On December 8, 1949, in London, Hector Munro, M.B., C.M., of 9, Queen Anne Street, London, W.1.

Ogg.—On December 5, 1949, at 1, Briardale Gardens, Hampstead, London, N.W., Theodore Alexander William Ogg, M.D.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pulmonary Tuberculosis

Q.—*(1) I should be grateful for information about pneumoperitoneum and its advantages over other methods of collapse therapy, with special reference to phrenic nerve operations. How soon can a pneumoperitoneum be started, and what are the risks and contraindications? (2) What improvement may occur in tuberculous women as a result of pregnancy?*

A.—(1) The fullest information available about pneumoperitoneum is contained in A. L. Banyai's *Pneumoperitoneum Treatment*, published in 1946. Many physicians would consider that this presents a rather too enthusiastic view of the part played by this form of treatment in pulmonary tuberculosis. A very adequate, though less full, general account of artificial pneumoperitoneum in pulmonary tuberculosis will be found in the second edition of Kayne, Pagel, and O'Shaughnessy's *Pulmonary Tuberculosis*, edited by Pagel, Simmonds, MacDonald, and Fatti (1948). Only a few general observations can be made here. Pneumoperitoneum is best regarded as an adjunct to phrenic paralysis; unless the diaphragm is made rigid by old inflammatory changes, especially pleural, pneumoperitoneum allows the paralysed diaphragm to rise very high in the chest and thus effect selective relaxation of one lung. This relaxation is less complete than that obtained by a good artificial pneumothorax, but the possible pleural complications of pneumothorax are of course avoided. The treatment of recent acute tuberculous lesions by artificial pneumothorax leads to a high incidence of serous pleural effusions and empyemata; even if these are eventually absorbed they lead to gross pleural thickening and consequent serious diminution of pulmonary function. Hence in the treatment of such acute cases artificial pneumothorax is now generally avoided. Phrenic paralysis and pneumoperitoneum, however, can be instituted immediately without giving rise to the risks associated with pleural reactions. Hence these acute cases with predominantly unilateral disease form an important indication for pneumoperitoneum and phrenic paralysis. In such cases pneumoperitoneum should be regarded as probably only a preliminary to some further form of treatment. Phrenic paralysis and pneumoperitoneum may also be used as an adjunct to rest in bed in the treatment of less acute and less extensive lesions.

The only positive contraindications to pneumoperitoneum likely to be encountered are active tuberculous peritonitis and the presence of old peritoneal adhesions from any cause. Complications include air embolism, which seems to be nearly as frequent as in artificial pneumothorax; peritoneal effusion, which is very much rarer than pleural effusion in artificial pneumothorax and probably occurs in no more than 1 or 2% of cases; the accidental induction of pneumothorax if the pneumoperitoneum refills are given through the lowest intercostal space; pneumomediastinum; and the production of herniae in the usual hernial orifices, probably because of the increase in intra-abdominal pressure.

(2) This question also is difficult to answer briefly. It was the opinion of French physicians in the latter half of the nineteenth century that pregnancy actually benefited tuberculous women, and many physicians would agree that during pregnancy the general condition of tuberculous women often improves considerably. On the other hand, obstetricians take a gloomy view of the fate of the tuberculous woman after delivery; and physicians in general would agree that it is in the months after delivery that relapses of tuberculous disease tend to occur. Such statistical evidence as is available indicates that no ultimate difference in result will be found in comparable groups of tuberculous women who have borne children and of those who have not. This suggests that the slight improvement which occurs during pregnancy is offset by the greater tendency to relapse in the months after delivery. Certainly there is no statistical evidence to justify routine termination of pregnancy in tuberculous women. Recent papers worth consulting on this point include those by Stewart and Simmonds (*British Medical Journal*, 1947, 2, 726). Cohen (*Brit. J. Tuberc.*, 1946, 40, 10). and Friedman and Garber (*Amer. Rev. Tuberc.*, 1946, 54, 275).

Lymphocytosis in Whooping-cough

Q.—*A relative and pronounced lymphocytosis is an outstanding feature of an attack of whooping-cough. Is there any relationship between the severity of the attack and the degree of lymphocytosis? Is an injection of whooping-cough vaccine followed by lymphocytosis?*

A.—A leucocytosis with lymphocytosis (over 60%) is a characteristic response in whooping-cough, but no satisfactory explanation for its occurrence has yet been given. The lymphocytosis is most marked in the paroxysmal and whooping stages of the infection. It may be absent in infants under 6 months of age and, as infection is often very severe in infancy, the lymphocytic response cannot be regarded as a prognostic sign. Very high leucocyte counts, up to 100,000 or more per c.mm., are often found in cases with complications, such as bronchopneumonia, in which the total lymphocyte count may reach 60,000 per c.mm., but here the secondary bacterial infection may be an added stimulus. A lymphocytic response of varying degree to pertussis vaccine has been reported by Sauer (*J. Amer. med. Ass.*, 1933, 100, 239) to occur in some 60% of young children after two or three injections of vaccine.

Causes of Death

Q.—*(a) What are the commonest killing diseases in adults in order of frequency? (b) What groups of diseases—for example, cardiovascular, respiratory, alimentary, etc.—are responsible for most deaths, and has there been any change in the last 50 years?*

A.—*(a)* The numerical importance of a cause of death depends on the sex and the period of life considered. The most important causes of death for three broad age groups for the most recent triennium available are:

Actual Number of Deaths, 1945–7

Cause	Males					
	20–39 Years		40–59 Years		60 Years and Over	
	No.	% of All Causes	No.	% of All Causes	No.	% of All Causes
Tuberculosis ..	12,189	31·98	16,115	11·18	7,329	1·48
Cancer	3,083	8·09	29,658	20·58	78,666	15·88
Intracranial lesions of vascular origin ..	461	1·21	8,715	6·05	60,645	12·24
Heart diseases ..	3,625	9·51	30,151	20·92	166,629	33·63
Bronchitis	914	2·40	10,820	7·51	39,808	8·04
Pneumonia	1,175	3·08	5,662	3·93	15,931	3·22
Nephritis	1,496	3·92	4,300	2·98	12,909	2·61
Violence	6,624	17·38	9,506	6·60	12,149	2·45
	Females					
Tuberculosis.. ..	14,585	35·31	5,735	5·35	2,387	0·46
Cancer	4,229	10·24	33,791	31·49	76,114	14·81
Intracranial lesions of vascular origin ..	611	1·48	11,117	10·36	82,809	16·11
Heart diseases ..	4,369	10·58	18,915	17·63	180,779	35·18
Bronchitis	627	1·52	3,459	3·22	29,953	5·83
Pneumonia	1,187	2·87	3,072	2·86	15,149	2·95
Nephritis	1,441	3·49	3,909	3·64	12,758	2·48
Violence	2,557	6·19	4,330	4·04	11,839	2·30

(b) The second part of this question presents some difficulties. The fall in the death rates in each age group during the past 50 years has considerably modified the age structure of the population and the risk of dying from specific causes. Owing to the changes in classification and tabulation that have been made during this period because of the increase in medical knowledge a comparison of deaths over a series of years up to 1940 is open to objections. The introduction in 1940 of the

physician's preference when two causes are associated makes it impossible to compare the present classification with that of earlier years. A comparison of the deaths in 1931 with those in 1947, the longest series that can safely be used, is as follows:

Disease	1947		1931	
	No. of Deaths	% of All Causes	No. of Deaths	% of All Causes
Tuberculosis	23,075	4·5	34,959	7·1
Cancer	79,706	15·5	60,162	12·2
Diseases of the nervous system	65,458	12·7	50,781	10·3
Diseases of circulatory system ..	164,015	31·8	103,268	21·0
Diseases of respiratory system ..	60,740	11·8	80,279	16·3
Diseases of digestive system ..	21,044	4·1	25,785	5·2
Diseases of urinary system ..	20,411	4·0	25,354	5·2
Violence	19,826	3·8	21,395	4·4
Other causes	61,316	11·9	89,647	18·2
All causes	515,591	100	491,630	100

The crude death rate in both years was 12.3 per 1,000. The changes in the relative importance of the various groups of diseases, especially those which are the most frequent cause of death in old age, have been largely due to the decrease in the death rates throughout life, which has resulted in more people living to older ages than formerly.

Vitamin D_2 for Chilblains

Q.—*For the past four or five years I have been using ampoules of calciferol containing 600,000 i.u. of vitamin D_2 with great success in the treatment of chilblains, so far without any ill effects. I gave six ampoules—one each week. Recently I have been told that there is danger of calcification of the renal tubules with this treatment. Is this correct, and is the danger great enough to warrant stopping the treatment? Calciferol dragees, each containing 50,000 i.u. of vitamin D_2, are also obtainable. Would treatment by these be free from risk, and what dosage should be used?*

A.—A dose of 600,000 i.u. of vitamin D_2 per week is approaching an amount which can produce toxic symptoms. These may appear with a dose of 100,000 units daily. The use of large doses of vitamin D_2 is not free from risk, the chief results of overdosage being hypercalcaemia with calcification of the kidneys and blood vessels, anorexia, lassitude, headache, and albuminuria. *No controlled observations have been made to show that vitamin D is effective in the treatment of chilblains, and to use a drug in toxic doses for this purpose is hardly justified.* The rationale for the use of vitamin D in the treatment of chilblains rests on the false assumption that a raised blood calcium level will decrease capillary permeability, which may be increased in patients with chilblains. The prolonged use of doses of 50,000 units or more of vitamin D a day is justified only in the treatment of lupus vulgaris, and then it should be controlled by blood calcium estimations.

Boils in Ear

Q.—*How should a case of recurrent boils in the ear be treated?*

A.—Recurrence of boils in the ear may be due to general or local causes. Such diseases as diabetes and nephritis must therefore be excluded. Carbohydrate intake should be reduced, and a varied and well-balanced diet is important. Locally, care must be taken that cross-infection of the meatal wall is avoided, and that a chronic dermatitis does not result from the acute stage. A wick soaked in magnesium sulphate paste, which is generally preferable to aluminium acetate, will help. For some weeks after the acute stage is over the meatus should be mopped out with spirit 75%, or 2% gentian violet in spirit. If a chronic dermatitis is present it should be treated on the usual lines—as, for example, with linimentum calaminae. Various measures may be tried to raise the bodily resistance to staphylococcal infection, but the results are often poor. Ultraviolet-light baths to the whole body two or three times a week for four weeks have been advised by some authorities. The questioner might also refer to the article by W. M. Mollison which appeared in the *Journal* of October 22 (p. 923).

NOTES AND COMMENTS

Estimation of Erythrocyte Sedimentation Rate.—Dr. JAMES KELMAN (Perth) writes: In "Any Questions?" (November 12, p. 1127), in answer to the query whether flocculation should occur in the 3.8% citrate solution (taking this to refer to the blood-citrate mixture), it is stated that "if gross agglutination or flocculation occurs then either the blood has started to clot or the patient is suffering from gross hyperglobulinaemia, the most common cause of which in this country is myelomatosis." Granularity of the sedimenting cells is not infrequently to be found in any very rapidly sedimenting blood, but it has to be looked for. Using a micro-method which involves mixing citrate and blood on a cell slide, I have seen flocculation occurring on the slide on a number of occasions in blood from persons in the acute stage of severe scarlet fever and also in cases of active pulmonary tuberculosis. Balachowsky, S. (*Rev. méd. Suisse rom.*, 1923, **43**, 714), drew attention to this phenomenon, and declared it to be of bad prognosis. This was certainly not so in my scarlet fever cases, all of whom made a good recovery, but in the tuberculosis cases the longest period of survival was six months. The effect of tilting the tube, also mentioned in your reply under this heading, can be very marked. Wintrobe, M. M., and Landsberg, J. W. (*Amer. J. med. Sci.*, 1935, **189**, 102), state that even a difference of two or three degrees may accelerate sedimentation up to 30%. It is interesting however to note that Balachowsky in an earlier article (*Bull. Mém. Hôp. Paris*, 1925, **49**, 1141) showed that quick results could be obtained by using a stand which fixed the tubes at an angle, but this method does not appear to have found favour.

High-pitched Voice in Adult Male.—Dr. VERNON O'HEA-CUSSEN (Cork, Ireland) writes: The reply given to the question on high-pitched voice in adult male ("Any Questions?" November 26, p. 1246) is incomplete. It is doubtful if in ordinary practice hormone deficiency is ever more than an accessory factor in producing the falsetto voice. In normal voice production the larynx is pulled downwards by the sterno-thyroid and sterno-hyoid muscles for low-pitched sounds. For high-pitched sounds the use of the supra-hyoid muscles is necessary. Men with falsetto and "pressor" voices use the latter set of muscles almost entirely for all sounds. By training such individuals to use the infra-hyoid muscles to draw down the larynx the required change of tone in the voice can usually be readily and permanently attained.

Intranasal Oil.—Dr. GEORGE W. C. JOHNSON (Harrogate) writes: The intranasal use of oily preparations was mentioned in "Any Questions?" (November 26, p. 1245). It is pertinent to add to the answer printed a reference to the possible danger of "lipoid-cell pneumonia" following the use of these substances. When a student in America a few years ago I was taught that oily preparations can be hazardous, especially for small children, if given intranasally. I have not myself seen any patients adversely affected, but perhaps I may mention the section on lipoid-cell pneumonia in *Cecil's Text-book of Medicine* (1947, p. 142, Philadelphia) and also the abstract (No. 1846 in *Abstracts of World Medicine* for October, 1949) of a paper by Schneider (*New Engl. J. Med.*, 1949, **240**, 284) concerning mineral oil in the lungs.

Copra Bug.—Mr. JOHN A. FREEMAN, Ph.D. (Chief Entomologist, Ministry of Agriculture and Fisheries), writes: May I refer to the reply to the first item of "Any Questions?" for October 22 (p. 939)? I think it is incorrect to state that the "copra bug" is to be identified with the mite *Tyrophagus castellani*. The insect commonly known as the "copra bug" is the Clerid beetle, *Necrobia rufipes* DeGeer, which is often very common on cargoes of copra and other "oil seeds." Although it is frequently accused by dockers of biting, there does not appear to be any evidence that it can do so. The irritation resulting from the handling of copra and other infested conditions is as your reply states, properly attributed to the presence, at some time, of the particular mite.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY DECEMBER 17 1949

THE SECRETARY REPORTS

RETROSPECTIVE APPLICATION

The terms and conditions of service now being implemented for hospital medical staff apply with retrospective effect to the appointed day. Boards have discretion to make adjustments of salary, items-of-service payments, expenses, etc., relating to the interim period, on the understanding that the effect to be achieved, so far as practicable, is that which would have obtained had the terms and conditions as a whole been in operation since July 5, 1948. Guidance on this subject is given in the explanatory memorandum issued by the Ministry with the terms and conditions of service.

General Application

In general, the salary will be adjusted in accordance with the practitioner's recent grading, except where different posts have been held since July 5, 1948. The retrospective adjustment will be made in relation to the amount of services rendered during the period for which an interim remuneration has been paid, and not—where there is an alteration—on the basis of the permanent contract.

Thus, a consultant who has been doing four sessions and is now offered a contract for six sessions will have his salary adjusted in respect of the interim period on the basis of four sessions. If the salary already paid in the interim period exceeds that to which the practitioner is now entitled retrospectively, the excess will not be recovered. But where under their old conditions whole-time officers have been permitted private fees the whole amount earned may be expected to be offset against any *upward* adjustment of remuneration. Similarly, where the interim rates of payment for domiciliary consultations were more favourable than the new rates (e.g., the 10 guineas payment for major operations) the overpayment, both in the case of whole-time and part-time practitioners, will be offset against any *upward* adjustment either of other domiciliary service payments or of salary.

On the other hand, fees for domiciliary consultations in excess of the maximum for which payment was made under the interim arrangements may be claimed at the new rates and subject to the new maximum where records of these cases have been kept.

Whole-time officers will not be required to pay back any fees paid for domiciliary consultations during the interim period. Where records have been kept pending settlement in the light of the new terms, the provisions of paragraph 14 (regarding the retention of fees for services outside the scope of the Service) may be implemented retrospectively.

Some adjustment may be necessary in respect of exceptional consultations carried out in the interim period. It was not the intention of the Ministry that this work within the area of the employing authority should attract additional remuneration where the consultant was already earning the interim maximum salary of £1,600. Therefore, if special payment has been made for these visits in cases where the consultant was employed for nine or more half-days per week, the payment will be offset against the adjustment now due to bring the interim salary up to the permanent terms. Where the consultant's interim remuneration was less than £1,600, or he was doing fewer than nine half-days a week, then if the application of the terms would bring the work within the assessment of part-time services, and an adjustment of the number of half-days is possible, such adjustment will be made and the items-of-service payments already made for exceptional consultations will be offset against the upward adjustment of remuneration.

The new salary scales are gross, and therefore any reduction for emoluments will be retrospective to July 5, 1948.

If sick leave has been taken during the interim period the balance of pay will be paid in cases where the new conditions are more favourable than the old. If less favourable, the overpayments will not be recovered or offset against other adjustments.

The new rates of travelling allowances and expenses, where higher than those previously operative, may be applied retrospectively so far as possible. Where a detailed adjustment is impracticable, settlement may be made by agreement with the practitioner.

The initial special distinction awards will be applied retrospectively, but application of the terms will not be withheld in expectation of a distinction award except at the consultant's request.

Retrospective adjustment of salaries will be made to practitioners who have resigned or retired, and to the estate of those practitioners who have died since July 5, 1948.

The provision in the terms for the medical examination of officers on appointment does not apply retrospectively.

Medical Superintendents

The arrangement under the terms for the apportionment of the salary of medical superintendents according to the proportion of time devoted to clinical and administrative work is retrospective, except for those transferred officers who elect to retain their old salary and conditions of service.

Registrars and House Officers

In the case of these officers the *post or posts* held by a practitioner from time to time since July 5, 1948, will be classified and the new rates of remuneration then adjusted retrospectively to the post or posts. Overpayments of salary need not be recovered. This applies also to the holders of supernumerary posts under the scheme for postgraduate education of ex-Service practitioners; where the post held by a Class III officer is now graded as a house-officer post, the remuneration at the rate appropriate to a Class III officer should be allowed to stand.

House officers will have the period since the date of registration during which posts in this grade have been held divided into six-monthly periods, their interim remuneration being adjusted at the rate of £350, £400, and £450 in respect of the first, second, and third or subsequent six-month periods.

Boards of governors, regional boards, and hospital management committees are proceeding with the necessary adjustments, and where payment has not already been made members of hospital medical staffs may expect to receive any sums to which they are entitled in due course. In the absence of an automatic settlement application should be made in the case of consultants and senior hospital medical officers to the regional board, and in the case of other staff to the hospital management committee, except in the teaching hospitals where the claims should be to the board of governors concerned

SPECIAL DISTINCTION AWARDS

The Council of the Association and the Central Consultants and Specialists Committee have given careful consideration to the question of special distinction awards. They feel that neither body, nor the Regional Consultants and Specialists Committees, should take any active part in the procedure for selecting consultants for these awards—as, for example, by recommending the names of individual practitioners. The following comments and suggestions have, however, been forwarded to the Advisory Committee on Merit Awards.

Assessment of Merit

Merit should be defined as the total professional value of the consultant to the community, and the following factors should be taken into consideration in assessing merit:

(*a*) The nature and responsibility of the post (or posts) held, and the standard of efficiency attained in the performance of the duties of the post (or posts).

(*b*) Professional qualifications and academic or other professional attainments.

(*c*) The value of the consultant's researches and of his published works.

Procedure for Obtaining Evidence

One of the major difficulties of the National Committee will be the obtaining of reliable evidence on the relative merits of consultants throughout the country. All consultants have been asked to give details of their professional careers, and this information will prove of value to the National Committee. The committee will nevertheless need to be guided to a very large extent by a balanced local opinion on the respective merits of individual practitioners.

For this reason it is recommended that the National Committee, in consultation with boards of governors and regional hospital boards, should establish in each region a committee composed of distinguished practitioners of consultant status who are not themselves interested in merit awards (i.e., being already in receipt of the highest award or retired from practice), and that these committees should be asked to select consultants in the region for recommendation to the National Committee.

Publicity

It would be undesirable that any publicity should be given in the lay press to the practitioners who receive awards, but at the same time information regarding the awards should be available to the profession. If this principle is accepted, it follows that there should be no publication of lists of recipients even in the medical press.

Accordingly it is urged (*a*) that a list of recipients should be made available to the Joint Committee and to its constituent bodies; (*b*) that boards of governors and regional boards should inform medical committees and medical advisory committees of the names of the recipients in their areas (apart from this the boards should be instructed to regard information relating to awards as confidential); and (*c*) the Joint Committee and its constituent bodies should also be informed of the distribution of awards in the various regions and among the various specialties.

INVALIDED FROM H.M. FORCES

MEDICAL REPORTS AVAILABLE

The Ministry of Health reports that Service Records Offices are receiving many requests from medical practitioners for information contained in the medical reports of personnel invalided from the Forces. These applications should be addressed to the area executive council.

[illegible] of October 22 (p. [illegible] the Ministry of Health, and [illegible] executive council for the area where the person concerned has his permanent address. Where the invalided person has given consent on the relevant form to the disclosure of the medical history, the medical report should be sent to the doctor who has accepted that person on his list for medical treatment.

ABUSE OF HEALTH SERVICE

CHANGES OF DOCTOR

The opinion that the National Health Service is being abused was expressed at a recent meeting of the executive council for the county of Ayr. During the first year of the Service 4,016 people have changed to another doctor in the same district of Ayrshire. The executive council passed the following resolution, sending copies of it to the Secretary of State for Scotland and the Scottish Association of Executive Councils:

That the Executive Council for the County of Ayr are of opinion that the administration of the National Health Service Act has disclosed abuses in the use of the services provided by it; that the right of persons on a doctor's list to change their doctor at any time, without notice, facilitates abuse of the general medical service; that the procedure for change of doctor which was required under the National Health Insurance Acts would tend to prevent such abuse, and the Council advise that that procedure be instituted

CIVIL SERVICE APPOINTMENTS

EXAMINATION OF CANDIDATES

The Air Ministry has informed the Association that, when a candidate for an established Civil Service post in that Department is medically examined, the practitioner will be paid a fee of 25s. for the form of report required. This change brings the Air Ministry into line with other Government Departments.

GENERAL PRACTITIONERS AND HOSPITALS

SCOTTISH INQUIRY

The Secretary of State for Scotland has asked the Scottish Health Services Council to advise him on how a closer working relationship can be achieved between the general practitioner and the hospital and specialist services. This may be an important step towards making available to general practitioners facilities to look after their own patients in certain types of hospital.

The council has been asked to consider:

The availability of the hospital laboratory services and the consultants in laboratory medicine to the general practitioner.

The duties which general practitioners could discharge as members of hospitals staffs.

The extent to which accommodation in general and cottage hospitals should be available to general practitioners for treatment of their own patients.

The means whereby the general practitioner in an area can best be kept in touch with the consultants on the staff of the hospitals serving that area.

GENERAL PRACTITIONERS' REMUNERATION

DEPUTATION TO MINISTRY

The following deputation appointed by the General Medical Services Committee will go to the Ministry of Health on December 22 to discuss the resolutions passed by the G.M.S. Committee at its meeting on December 1 (*Supplement*, December 10, p. 252): Dr. S. Wand, Dr. E. A. Gregg, Dr. W. Jope, Dr. H. G. Dain, Dr. F. Gray, and Dr. W. M. Knox.

Questions Answered

Certificate for Midwife

Q.—*With regard to the certificate required by a midwife for gas-and-air analgesia, I should be grateful for guidance on the following points: (a) Apart from examining heart, lungs, and urine, is any antenatal examination required? (b) If no antenatal examination is required, from whom is the certificate fee claimed?*

A.—The Central Midwives Board requires a midwife at some time during the pregnancy to obtain a certificate from a medical practitioner to the effect that the patient has been examined to determine whether or not there is "any abnormality to contraindicate the administration of gas-and-air analgesia" by the midwife. The wording quoted above is that suggested by the Central Midwives Board, and no exact details of the examination are specified. The examination does not include an antenatal examination. The medical certificate is not included among those which the Ministry has decided must be given to a patient without charge

Specimens in the Post

Q.—*In view of the stringent regulations of the Post Office regarding the posting of specimens, published in the Supplement of October 15 (p. 169), what provision is made to provide general practitioners with the requisite containers?*

A.—In some instances laboratories and institutes supply the receptacles, but where that is not the case the practitioner dispatching the specimen is responsible for providing the receptacle and for ensuring that the package complies with the Post Office regulations.

Assistant's Superannuation

Q.—*I am employing an assistant with view to partnership in due course. He has worked hitherto in a hospital and has been paying superannuation contributions. Am I liable to pay superannuation contributions on his behalf, and, if so, to whom, and in what proportion?*

A.—The principal as the employing authority is required to pay 8% of the assistant's salary. The assistant himself pays 5%. The assistant's salary should be notified to the executive council (excluding car allowance), which will then deduct 14% of this amount from the principal's remuneration. Six per cent. is recoverable by the principal from the sums paid to the assistant.

Effect of Act on Partnerships

Q.—*By partnership agreement made before July 5, 1948, I have a quarter-share. The senior partner and myself joined the National Health Service. After a period of five years, that is to say in 1953, I have the option of making my share one-third by payment to the senior man of a stated sum of money. Does this entail my paying the money, or does the State take over this responsibility and allow me to become owner of one-third?*

A.—The Amending Bill, now before Parliament, deals with this point explicitly, and the following are the relevant clauses. Any ambiguity which at present exists will remain only until the Bill becomes an Amending Act in the near future.

Section 1 (3).—Section thirty-five of the National Health Service Act, 1946 (hereafter in this Act referred to as "the Act of 1946"), which prohibits the sale of medical practices, shall not affect, and shall be deemed never to have affected, the exercise or performance under any partnership agreement to which this section applies (i.e., "any partnership agreement in force on and immediately before the Appointed Day") of any right or obligation of a partner to sell to, or purchase from, another partner any share in the goodwill of the partnership practice, but any such agreement shall have effect subject to the following provisions of this section.

Section 1 (5).—Where any agreement to which this section applies imposes an obligation or confers an option on a listed or new listed partner to purchase the share of another partner being a listed partner in the goodwill of the partnership practice, and, in the case of an option, the option has been exercised, that share shall be transferred at the time and on the terms (except as to the payment of the purchase price) provided in the agreement, and there shall be paid to the partner from whom the share is transferred, on or as soon as possible after the completion of the transfer, in complete satisfaction of the purchase price, the compensation determined as aforesaid in respect of that share.

Heard at Headquarters

Unfathomable

Much has been heard about the millions and prospective millions in the medical pool for general practitioners in the N.H.S., or, as it is sometimes called, the "kitty," but the doctors on the General Medical Services Committee the other day were rather abashed to hear their dental colleague—an observer who sits on the committee as representing the parallel dental body—describe it as only a "puddle." He compared it, to its disadvantage, with the dental pool, which, he said, was "unfathomable." The dentists are not remunerated from a pool at all.

A New "High"

A new high record has been reached in the Association membership. In the middle of September it stood at 62,334, being over 2,000 more than the figure in April. The percentage of membership to the total profession in the United Kingdom is 77, and the percentage to the working profession (that is, excluding retired practitioners) is just on 79. Saturation must one day be reached, but an average accession of 100 new members a week during the last five months gives no sign of it

Canadian Tour

Sir Lionel Whitby, Past President of the Association, carried out a strenuous tour of Canada when he went there as the Association's delegate at the end of August. He attended and addressed meetings in six of the Provinces, travelling out as far as Manitoba, and being prevented from going further west only by his commitments in the United States. Immediately on his arrival he spoke on "Nationalized Medicine" at a dinner given in his honour at Quebec, and he found this subject in demand wherever he went. He addressed a special meeting in Montreal of the Quebec Province Division of the Canadian Medical Association, and attended divisional meetings in New Brunswick, Prince Edward Island, and Nova Scotia. In Toronto he spoke at a large meeting of the medical faculty.

Booklet on Medical Ethics

The inexperienced doctor—and we have all been that at some time—often finds that medical ethics is a subject full of pitfalls and governs conduct in situations that sometimes catch him by surprise. The Association has therefore prepared a booklet setting out the main points of medical ethics that the practising doctor should know about. Council has agreed that it should be circulated to all members of the profession in the United Kingdom on qualification, to all those living in the United Kingdom, and to any others who like to apply for it. Sufficient copies have not yet been printed, but they should be available soon.

The Secretary of State for Scotland has appointed Miss E. W Himsworth, R.G.N., S.C.M., to be a member of the Scottish Health Services Council in place of Miss C. M. Keachie, R.G.N., S.C.M., H.V.C., who has resigned. Since 1946 Miss Himsworth has been superintending nursing officer, responsible for health visiting and midwifery services, of Aberdeen Town Council. She has been appointed by the council of the standing advisory committee on nursing and midwifery, local authority services, and health centres, and to the child health committee of the council.

INTERNATIONAL MEDICAL VISITORS BUREAU

The British Medical Association has established an International Medical Visitors Bureau in order to provide a personal advisory service to medical practitioners visiting the United Kingdom from countries outside the British Commonwealth. (For medical practitioners visiting the United Kingdom from countries within the British Commonwealth a similar service has been provided for some time by the B.M.A. in its Empire Medical Advisory Bureau.)

The International Medical Visitors Bureau is at British Medical Association House, Tavistock Square, London, W.C.1. Buses numbered 68 and 77 pass the door, and the nearest underground railway stations are Russell Square (Piccadilly Line) and Euston Square (Inner Circle and Metropolitan Lines). The Medical Director of the Bureau is Dr. H. A. Sandiford, to whom all communications should be addressed.

Information is available at the Bureau on postgraduate education facilities, and visits to hospitals and clinics can be arranged. Assistance in finding accommodation will be given. General information on food rationing, petrol allowances, cars, facilities for sports, travelling exhibitions, theatres, etc., is available.

It will enable the Bureau to be of most service if a visitor gives as long notice as possible of his intended visit to Great Britain, and information on the following lines would also be useful—projected date of arrival, mode of travelling, period of stay, main objects of visit, and requirements from the Bureau.

CERTIFICATE WITHOUT SEEING PATIENT

The London Executive Council on October 27 adopted the report of its medical services committee on a case which was raised by Mrs. A against Dr. B, her late husband's medical attendant.

According to the report, Mrs. A told the committee that her husband saw Dr. B on Monday, May 9, when he complained of pain in the back and ribs. The doctor thought that the pains might have been caused by rheumatism, and he issued a National Insurance certificate. On the following day Mr. A was feverish and complained of headache. Mrs. A saw the practitioner at his evening surgery and said that her husband looked yellow and appeared ill. According to her account the practitioner said that it was "a bore" to go out in the evening but that he would call the following morning. He did call on Wednesday, May 11, and found that the patient was jaundiced. He gave a prescription and some advice on the patient's diet. On Sunday, May 15, Mr. A was very feverish again, and his wife called on the doctor on the Monday to obtain a certificate. The doctor, prompted by Mrs. A, certified that the patient was suffering from "jaundice." He also gave her a prescription for tablets. On Tuesday, May 17, the patient was decidedly worse, and Mrs. A went to the doctor's surgery and asked him to call. The doctor immediately wrote out a certificate for the removal of the patient to hospital. Because of some misunderstanding it was about three hours before the ambulance arrived. The patient died on the way to hospital. The cause of death was obstructive jaundice due to a stone in the common bile duct.

Dr. B denied that he had said it was "a bore" to go out at night. He told Mrs. A that the diagnosis of jaundice was difficult in artificial light and that it would be better to see the patient in the morning. The following day he thought the patient was suffering from catarrhal jaundice, since there was nothing to indicate obstructive jaundice, and he prescribed "the usual alkalines and salines." He heard no more till he saw Mrs. A on Monday, May 16, when he gave her a certificate. Early the following day he could tell from her demeanour that events had taken a serious turn. He therefore telephoned for an ambulance and arranged for the admission of the patient to hospital. At the same time he wrote a certificate for admission, giving "Jaundice—? liver necrosis" as the diagnosis. He had not gone to see the patient on this occasion because he considered that the time would be better spent in arranging for prompt admission to hospital.

Findings

The committee found as facts that the practitioner was requested to visit the patient on May 10 and visited him on May 11; that on May 16 the doctor was informed by Mrs. A of the seriousness of her husband's illness; that a certificate of incapacity was issued, although the patient had not been examined since May 11; and that a request for a visit on May 17 resulted in the issue of a certificate for admission to hospital.

While the committee took the view that nothing the practitioner could have done would have prevented the patient's death, they held that the standard of care provided fell short of that required under the terms of service. The practitioner should not have issued a certificate to a patient whom he knew to be ill and who had not been examined for five days previously, and he should not have arranged for admission to hospital without first satisfying himself that the patient was in a fit condition for removal. The committee therefore concluded that the practitioner concerned failed to comply with the terms of service in that a certificate of incapacity was issued on May 17, 1949, without his seeing the patient; and that the standard of care fell short of that required of a practitioner participating in the National Health Service.

The committee recommended "that the practitioner be censured; that representations be made to the Minister of Health that, owing to the failure of the practitioner to comply with his terms of service, the sum of £25 be withheld from his remuneration; and that the complainant, the practitioner, and the Minister of Health be informed accordingly."

Correspondence

Domiciliary Visits

SIR,—The introduction of the domiciliary consultation scheme was received by most of us with enthusiasm, because it seemed to promise, among other advantages, the prospect of a closer relationship between hospital consultants and family doctors. The gap between consultant and general practitioner has unfortunately been growing in the past, and Dr. J. M. Lipscomb[1] has recently well described its unfortunate effect on the patient who attends a hospital out-patient department. Now, it is clearly unreasonable to expect a family doctor to accompany every case he sends to out-patients, but one had hoped that the domiciliary consultation would enable him more often to meet consultants and to discuss personally with them in the patient's home, at least some of his problems. Such personal contacts had, before the introduction of the scheme, been limited to occasions when private patients could afford a consultant's visit, and had in some practices been rare. Equally one hoped that the consultant would likewise benefit by closer personal contact with his general practitioner colleagues.

These advantages of the scheme are so obvious that one would think they hardly needed emphasis. Yet it would seem that there is a widespread and growing custom whereby a family doctor rings up a consultant (or his secretary, or the hospital bureau) and notifies him that he would like a patient visited some time. The consultant visits the patient when he chooses, and later writes to or rings up the doctor to give him his opinion. This practice, which one might term a "domiciliary visitation," seems to have only about half the value of domiciliary consultation. Its apologists say (*a*) that the family doctor often is too busy to be able to fit such a consultation, which may take half an hour or more, into his day's work, or (*b*) that the consultant has so many requests for domiciliary visits that he cannot fix definite times for them, but must do them whenever he has a spare moment.

To (*a*) one might reply that if a doctor cannot make time to meet a consultant over an occasional difficult case he must be singularly uninterested in his work; alternatively, if he requires the services of consultants so frequently that the consultations seriously encroach on his time, that he must be somewhat lacking

in diagnostic ability or, if he himself requires no guidance, remarkably unresistant to the demands of importunate relatives. To (*b*) one might reply that the consultant has the remedy in his own hands. He can refuse to do any domiciliary visit unless the family doctor also attends; he would then no doubt find that the number of visits he was asked to do would diminish. Unfortunately, so too would his remuneration at the end of the quarter, and to some this is a potent deterrent to action.

There are other objections to the domiciliary visitation, as contrasted with the domiciliary consultation. The disadvantage to the consultant of the absence of the family doctor's assistance in the matter of history and background is obvious. Often the consultant must hedge in his answers to the patient for fear of unwittingly "letting the family doctor down." Moreover, if he thinks that immediate action, such as removal to hospital, is required, he is often put in an awkward dilemma unless he can (as is seldom possible) get into immediate contact with his colleague. The family doctor loses because the consultant may, in all innocence, make a remark to the patient which the latter interprets as indicating a blunder on the part of the family doctor; or some point of advice to the patient which he wished the consultant to make or to reinforce may be missed. In practically every case the patient does not receive from the scheme the fullest advantage that he might.

One further point: there is little enough dignity left to our learned profession these days. Domiciliary visitations seem to savour uncommonly of "mechanization" and of all the worst implications in the term of "State medicine." Not so long ago, and perhaps even now, the advent of a consultant, and the ordered ritual dignity of the consultation, were something of an event to a patient. Is it merely pompous to regret that such a thing should cease to be? Alas, one can foresee a day not so far distant when the question, "Mary, is that the gas-man come to look at the meter?" receives the reply, "No, Mother, it's the hospital man come to look at Dad."

Nevertheless, Sir, it is chiefly because I feel so strongly that what should be one of the best links between a consultant and his general practitioner colleagues is in danger of becoming rusty through disuse that I would like to urge a future universal strict adherence to the unwritten rule (for Heaven forbid that it should ever be the subject of yet another regulation!) that a domiciliary consultation is always in reality a personal meeting between colleagues—what, in fact, everyone has hitherto understood by the term "consultation."—I am, etc.,

Adwy, Denbighshire. JOHN FORBES.

Obstetrics in General Practice

SIR,—Much has been said recently on this subject, but as it is a matter of considerable importance, alike to patient and to doctor, it is surely worth while to consider what principle should guide us in our attitude to the new maternity medical service.

It can hardly be denied that the really important thing is what the expectant mother herself wishes. Clearly she should be free to decide whether the required obstetric services—antenatal, during labour, and post-natal—should be rendered to her by the doctor of her choice plus a nurse, or by a midwife plus an antenatal clinic.

After thirty years of the practice of obstetrics in general practice I know that when a patient comes and asks me to attend her she means me to look after her all the way through—to exercise real and continuous antenatal care, to "stand by" at the labour, and to watch over her afterwards. The introduction of the new scheme has not altered this in the least, and I am glad to find that it is so.

In respect to antenatal care, it is doubtful whether it is possible to ensure the safety of the patient without at least seven examinations. Supervision of the labour by the doctor can mean and should mean increased confidence of, and added safety to, the patient. It can mean and should mean greater relief at the end of the second stage. The puerperium surely demands at least six visits, apart from a late post-natal examination.

Continuity in responsibility should be one of the guiding principles in obstetrics, and I would venture to add that acceptance of such responsibilities, though it often involves hard work, late hours, and sometimes considerable anxiety, can add most notably to the interest of general practice, can give a most abiding sense of satisfaction (though never of complacency), and brings in full measure from patients and their husbands gratitude, often expressed and often equally obvious though unspoken.

The nominal role of medical inspector envisaged by the scheme, if accepted by the doctor, may well result in the complications of pregnancy, which generally arise insidiously, being missed, and unless the doctor is informed of the onset of labour and keeps in touch with its progress it is only too likely that he will not be readily available or in a position to render prompt and efficient treatment in some of those serious complications of labour which, as we all know, can arrive swiftly and menacingly.

It is not clear in whose sterile imagination this so-called maternity service was fortuitously conceived, but it is pretty clear that if the intention of the scheme is carried out it is of precious little use to the patient, somewhat humiliating to the doctor, and in effect places a premium on inadequate and incomplete service. It seems at least doubtful whether the two paltry minimum antenatal attendances are of very much more use to the patient than the fleeting and infrequent visits of the gentleman who calls to inspect the gas meter.

It might reasonably be inferred that I am not greatly enamoured of the new maternity service. It is true, however, that the new service is restrictive only by implication and by the insidious enticement of pecuniary considerations, but there is nothing beyond this to prevent a full and complete service being given. Quite seriously, and with all respect, I would urge the younger men starting in practice not to let the temptation of easy money lead them to acquiesce in, and practise, a scheme which is really a travesty of obstetrics, which is little short of an insult to an intelligent patient, and which is calculated to bring, at no distant date, discredit to the profession.—I am, etc.,

London, N.W.7. A. H. MORLEY.

Income Tax and Whole-time Appointments

SIR,—The recent decision of the council of the Royal Society of Medicine to raise the annual subscription to this society—a decision which we regard as a regrettable necessity—prompts us to draw attention to a position which we consider increasingly anomalous.

The income-tax authorities have for long allowed claims by general practitioners and specialists, who are assessed under Schedule D, for relief in respect of annual subscriptions to professional journals and learned societies and the replacement of equipment, books, etc.; but those of us who hold full-time hospital appointments and are assessed under Schedule E receive no such dispensation.

There are many doctors in our position who may be following for a decade or more after qualification the long, stony, and relatively poorly paid path towards an increasingly problematical consultant status to whom the need to keep in touch and abreast with day-to-day developments in the various branches of medicine is at least as important as to the more established members of the profession. We do therefore most strongly urge the B.M.A. to press for a revision of this invidious and inequitable state of affairs.—We are, etc.,

MICHAEL BOSTOCK.
Norwich. JOHN SIMPSON.

The Growing List

SIR,—I apologize if my reasoning is faulty, but there seems to be one point missed regarding the basic salary and whether it should or should not be paid.

Since my panel on July 1 was 900 (approx.) my remuneration for the period July–September was based on this figure. But on September 30 my panel had risen to 1,500 (approx.), and since the increase, if plotted on a graph, would be represented by a straight line (approx.) I presume that I would actually be at risk during that period for a panel of 1,200. In the same way,

as my panel by December 31 will be a little over 2,000. I shall not receive remuneration corresponding even approximately to the number of units to which I am at risk.

When in addition it is considered that as a squatter one is largely depending upon ill people for an income, in contrast to the established practitioners, it is not only a question of "at risk remuneration." One's work is often out of all proportion to one's panel.

Our leaders, however, both locally and centrally, do not suffer squatters gladly, so perhaps I should just be thankful for small mercies.—I am etc.,

Carlisle. M. LUDLAM.

Public Health Salaries

SIR,—Negotiations on the salaries to be paid to medical officers engaged in the public health service have been going on for some considerable time, but so far no decision has yet been reached. In fact, detailed discussion with the responsible organizations has not yet commenced. That being so, I feel that it is not yet too late to put on paper my own observations on the proposed salaries, which were published in the *Supplement* of January 29 (p. 45).

The salaries are based on population, seniority, and responsibility. A brief glance, however, at the scales and at the populations of the towns and cities of the country will reveal that very few medical officers of health, deputies, or senior medical officers will ever receive a salary comparable to that of a consultant, and yet many of these officers are in possession of equivalent qualifications and hold positions of great responsibility. It is not difficult to visualize the picture of a senior officer in one department spending the rest of his or her life as the senior officer of that department, yet because of a system of salaries based on population and not on responsibility or capability that officer will never get the salary of a consultant.

It may be argued that after many years there may be special payments on merit to these officers, but there are obvious drawbacks to such a system. I feel that officers in the public health service should be treated as their colleagues in the hospital service—i.e., that there can be more than one officer within a department who could be paid on a "consultant-in-public-health rate" and not reserve this salary to the few medical officers of health who will qualify for it because they happen to be in charge of an area with the requisite population. I would, however, suggest that the chief of the department should be given a merit award for his responsibilities, just as it is suggested that there should be merit awards in the hospital service.

The effect, I am sure, of this procedure would be to ensure a constant supply of medical officers for the service. In addition, it would stop the flow of medical officers from places with a small population to larger counties and cities, and so maintain the efficiency of the service.—I am, etc.,

Leicester. ALEXANDER HUTCHISON.

Catching the Chemist

SIR,—The letter under this heading from Dr. W. Edwards (*Supplement*, December 3, p. 247), and your annotation on the subject (*Journal*, December 3, p. 1283) are of importance to all N.H.S. practitioners.

Unfortunately Dr. Edwards has more or less contracted to do this catching. In para. 11 of his terms of service it says, "A practitioner shall comply with any reasonable request from his executive council to furnish orders on a form provided by the council for drugs and appliances for the purpose of testing," etc. Also, the testing scheme has been devised in agreement with representatives of the medical profession and the Pharmaceutical Society, I am informed.

What were our representatives doing to agree to such an ungentlemanly scheme?

The method you suggest, Sir, in your annotation of taking the chemist by surprise and asking him to hand over a few made-up prescriptions for testing is preferable and above-board. Is it too late now for our representatives to endeavour to annul this grossly unpopular scheme?—I am, etc.,

London, N.9. M. P. K. MENON.

Representative Meetings

SIR,—Even in these days when the Association's expenses are increasing at an alarming rate, surely there is one matter on which no economy should be attempted. No money should ever be spared which helps contact between the periphery and the centre. As reported by you, Sir, the vote went against my proposal in Council for an S.R.M. to consider the Council's constitution, but I think Dr. J. A. Pridham is wrong in his statement (*Supplement*, December 10, p. 255) that the cost was the chief reason why the Council voted in this way. The Treasurer made a statement of the cost of an S.R.M., but I am glad to say that I cannot recall any other mention of the matter.

Naturally I realize that attending an S.R.M. is a comparatively simple matter for a Londoner, and I am told that in some parts of the country Representative Meetings are viewed with apathy. But there is possibly a more cogent reason than distance for this apathy. Some representatives may feel that the R.B. is no longer the policy-forming body of the Association. In the crisis of 1948 it was not even consulted, and now, with many of the important issues in the hands of autonomous bodies, it has little say in anything but domestic issues. Representatives may also feel that, as the Council's activities are restricted in the same way, its constitution is not a matter of great importance.

That there is ground for such beliefs is a disaster. But the Representative Body must fight back. If it wants an S.R.M. to consider the Council's constitution, it must have one, but there are wider and more important issues for which it can fight if it wishes. What about all the brave talk of two years ago—grants-in-aid, curtailing the powers of the Minister, and so on. The R.B. is the only part of the Association that can foster such issues. Surely it is not going to lie down like a good dog just because it is told that things can't be changed.—I am, etc.,

London, N.W.1. R. HALE-WHITE.

Constitution of Council

SIR,—I, like Dr. Ronald Gibson (*Supplement*, December 3, p. 247), was amazed to read of the Organization Committee's proposals for altering the constitution of the Council and of the Council's virtual endorsement of them. It is evident that both have failed completely to implement the wishes of the Representative Body.

It is to be hoped that all members will give this matter their careful consideration. Council has been much criticized during the past few difficult years and has been accused (sometimes rightly, in my view) of being out of touch with the views of the majority of the profession. In rejecting Council's proposals for reforming its constitution at the A.R.M. at Harrogate the Representative Body was supporting the view that a far larger proportion of the members of Council should be directly elected by more numerous and smaller constituencies. The latest proposals make practically no improvement in this direction and, as Dr. Gibson points out, still give less than 50% of seats to directly elected members.

An attempt is being made to improve and strengthen the Association at this difficult period of its history, and it is desirable that every member should express his views by instructing his representative when the matter is again put before the Representative Body for its judgment.—I am, etc.,

Churchdown, Gloucester. H. G. DOWLER.

SIR,—I would ask members and Divisions of the B.M.A. to reject the Winchester proposals (*Supplement*, December 3, p. 247). Implied in these proposals is a grave censure on the Representative Body. The members who sacrifice time, convenience, and money to carry out their duties are to be asked to declare themselves unfitted to choose members of the Council from their body. I trust the majority hold a better opinion of their own capabilities. Carried out to its logical conclusion, the proposed exclusion of the Representative Body would result

a system analogous to that of the U.S.A., where the President nd Congress are elected by different groupings, with resultant rustration and halting government when they do not see eye to eye.

The proposals rest on a pathetic fallacy. This is the belief that when the apathetic doctors languidly affix their crosses against their favoured candidates they will rise up active, enthusiastic members of the B.M.A. What wishful thinking! Any divisional secretary, church worker, trade union organizer, or member of any organization can bear witness that in any group only a small minority are interested enough to carry on the real work.

Then again the proposals query the relationship of the autonomous bodies to the Association. Pedantic minds boggle at the idea of these bodies being a constituent part of the B.M.A. But may I point out that there is a similar highly successful organization that has been in existence for over a century—the bewilderment and envy of the world—the British Commonwealth? Perhaps if the B.M.A. were renamed the British dical Commonwealth these sticklers for precise definition ght see the vision of the future and not treat a living ganism as something to be analysed, typed, and preserved in legal document. Be that as it may, the present arrangements hance the strength and influence of both the parent body and ie autonomous bodies, and those who try to stultify them by pposition or carping criticism are doing a grave disservice to ll concerned.

For these reasons I would ask members and Divisions to reject any proposals for more reorganization of the Council by a sweeping majority. In my opinion it has already gone too far, as I consider the omission of members of Council elected by grouped constituencies to be a retrograde step.—I am, etc.,

A. V. J. RUSSELL.

Birkenhead.

SIR,—In his letter (*Supplement*, December 10, p. 255) the chairman of the Organization Committee says nothing to refute the accusations brought forward by Dr. Ronald Gibson. As a direct result of the A.R.M. at Cambridge the Council was obliged to review its constitution. It produced certain proposals at the A.R.M. at Harrogate which were unacceptable and which were referred back.

There is little doubt that sufficient support for the Winchester Division will be forthcoming to enable an S.R.M. to be called to carry out this long overdue reform and put an end to the delaying tactics which are such a prominent feature of medical politics to-day.—I am, etc.

D. R. GILLIES.

Ropley, Hants.

Academic Salaries at Cambridge

SIR,—We ask you to publish certain further facts relating to scales of stipends at Cambridge (*Journal*, October 29, p. 988. and see *Cambridge Reporter*, October 13, p. 200).

	Non-medical	Pre-clinical	Clinical
	£	£	£
Readers	1,800 and 1,600	1,800 and 1,600	2,000 and 1,800
Lecturer	750–1,250 (by 50)	750–1,250 (by 50)	850–1,450 (by 100)
Demonstrator or assistant lecturer	600–700 (by 25)	600–700 (by 25)	700–800 (by 25)
Departmental demonstrator		350 (No F.S.S.U.)	

In certain cases (both medical and non-medical) there are additional pensionable payments up to £120.

The scale for teaching officers ordinarily resident in College is £100 less than that shown.

For the medically qualified man these scales provide stipends which, by comparison with other medical schools, attract him to teach in Cambridge in a position where he may be at a financial disadvantage amounting to some £6,000 of pensionable stipend during his first 10 years of appointment (due to the low annual increments), and at a final disadvantage of over £400 of annual pensionable stipend. It is only reasonable to suppose that these considerations may weigh heavily with the man who lacks private means but has a growing family, for which the "amenities of Cambridge" ought not to be measured thus.

These scales were approved by the University on Saturday, December 3. Many eminent men, both medical and non-medical, opposed this approval, which in their opinion would create a grave risk to the future of medical teaching in Cambridge—a risk which was avoidable and which therefore should not be incurred. They pointed out that in a comparable university different decisions had clearly been made in the national interest, with a proper appreciation of the problems arising from the nationalization of medicine and the Spens Report. They were refused permission to disapprove only of those stipends with which they were obviously concerned, and were heavily defeated by a large non-medical vote.—We are, etc.,

G. W. HARRIS,
University Lecturer in Physiology
M. M. BULL,
University Lecturer in Anatomy

Cambridge

Keep Agreements

SIR,—So Mr. Aneurin Bevan has refused the doctors' "application for higher pay." How misleading words can be when only partially true.

The "application" was one to settle what the doctors' payment should be, and before it was settled the Health Scheme started and doctors were made a payment on account, the difference to be made up to the doctors when it was settled just what the Spens Committee recommendations meant in terms of 1949 values. At the time the Health Scheme started it was agreed that the provisional payment was low, and both the B.M.A. and Ministry of Health agreed to abide by the Spens recommendations. It has been proved by the B.M.A. that the Spens Committee's Report is not being implemented.

Many millions sterling are being wasted by this Government elsewhere, and I do not agree that the doctors should be made to pay for it. Mr. Bevan, if not exactly breaking his word, is trying to get round it. We are not asking for an increase but for the fair payment originally agreed upon by both sides.

Mr. Bevan is treating us with contempt, a contempt we shall deserve if we do not make it brutally clear that we will not work this scheme unless agreements are kept.—I am, etc.,

A. H. LEVERS.

Leigh-on-Sea, Essex.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on October 1, 1950. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

Conditions of Award: Applications for scholarships must be made on the prescribed form, which may be obtained from the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to submit the names of three referees who are competent to report on the value of the research contemplated.

Diary of Central Meetings

DECEMBER

19	Mon.	Armed Forces Committee, 2 p.m.
20	Tues.	Organization Committee, 11.30 a.m.
21	Wed.	Protection of Practices Subcommittee, 11.15 a.m.
21	Wed.	Film Committee, 2 p.m.
22	Thurs.	Assistants Subcommittee, 11 a.m.
22	Thurs.	Occupational Health Committee, 2 p.m.
29	Thurs.	Committee *re* Prescription of Tuberculosis, 2 p.m.

JANUARY

5	Thurs.	Anaesthetists Group Committee, 2 p.m.
6	Fri.	Library Subcommittee, 11 a.m.
6	Fri.	Science Committee, 2 p.m.
13	Fri.	Tuberculosis Group Committee, 2 p.m.
19	Thurs.	Planning Subcommittee, 10.30 a.m.
19	Thurs.	Joint Committee of the B.M.A. and the N.V.M.A. 2 p.m.
26	Thurs.	Committee on Psychiatry and the Law, 2 p.m.

Branch and Division Meetings to be Held

BURTON-ON-TRENT DIVISION.—At Little Theatre, Guild Street, Burton-on-Trent, Tuesday, December 20, 8 p.m., (1) Sound Film: "Angina Pectoris"; (2) Colour Film: "Intraocular Foreign Bodies."

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport, Sunday, December 18, 4 p.m., lecture by Dr. H. L. Marriott: "Recent Medical Advances of Practical Importance."

WINCHESTER DIVISION.—At Royal Hotel, Winchester, Saturday, December 17, 7.30 for 8 p.m., dinner. Mr. N. Leigh Taylor: "Some Legal Aspects of the National Health Service Act."

Meetings of Branches and Divisions

DUMFRIES AND GALLOWAY DIVISION

A meeting of the Division was held at Dumfries and Galloway Royal Infirmary on October 30, when Mr. G. M. Sleggs gave an interesting address on "Old and New Orthopaedics."

There was also considerable discussion during the business part of the meeting about the recent circular issued by the Western Regional Hospital Board debarring general practitioners from any part in the examination or treatment of a patient booked for confinement at Cresswell Counties Maternity Hospital as a Group 1 Maternity Hospital. The following motion was passed:

"That this Division desires to protest against the excluding of antenatal and post-natal care of a patient by a general practitioner where the confinement is booked at Cresswell Counties Maternity Hospital as a Group 1 Maternity Hospital, especially in a rural area such as this hospital serves."

Discussion also took place on the allocation of the Mileage Grant for the area.

COVENTRY DIVISION

An ordinary general meeting of the Division was held on November 8 at the Coventry and Warwickshire Hospital. Dr. R. S. Rudland took the chair, and the B.M.A. Lecture, 1949, was delivered by Dr. J. St. Clair Elkington, his subject being "Diagnosis and Management of Epilepsy of Late Onset." The lecture was well illustrated by lantern slides and was greatly appreciated by the Division. An enthusiastic vote of thanks was accorded to Dr. Elkington at the close of the lecture on the proposition of Dr. W. D Coghill, seconded by Dr. J. Ballantyne.

DARLINGTON DIVISION

The annual general meeting of the Darlington Division was held on November 1, with Dr. B. B. Freshwater in the chair. Eighteen members attended. The following office bearers were also elected: deputy chairman, Dr. A. Morrison; treasurer, Dr. A. Woodman; secretary, Dr. W. F. A. Heron, 15, North Road, Darlington (Telephone: 2155).

The formation of a new Branch to be called Allside was discussed. A meeting of Branch representatives was held on November 6 to vote on the formation of this Branch. Clinical meetings are being arranged by the medical and surgical staff of the Darlington Memorial Hospital; the first meeting was held on November 10. The possibility of establishing a Sunday rota of duties was discussed, but at the moment the response was said to be poor. The annual dinner will be held on December 15, when Dr. Grey Turner will be guest of honour.

AUTHORS AND PSYCHOPATHS*

BY

W. RUSSELL BRAIN, D.M., F.R.C.P.

Physician to the London Hospital and the Maida Vale Hospital for Nervous Diseases

Of what interest, you may be wondering, is the psychopathology of authors except perhaps to the psychiatrist? I hope to show that it raises questions of considerable importance, primarily to doctors, but indirectly to everyone else. The relationship of mental instability to genius in general may seem to be of merely theoretical interest, but, since authors directly influence the minds of their fellow men more deeply than any other kind of genius, their mental peculiarities possess great social implications. Moreover, if we conclude that there is some positive relationship between their abnormalities and their achievements, we may find in this creative tension a contribution to the solution of the problems that confront many of our ordinary patients. Finally, our appreciation of an author's writing is greatly enriched by an understanding of his psychology.

At this point two possible objections need to be considered. Is it not enough, you may think, for us to enjoy the works of genius without bothering to analyse how they came to be produced, if, indeed, it is possible to do so? Wordsworth thought that nobody ought to pry into the lives of authors. "Our business," he said, "is with their books—to understand and to enjoy them. And, of a poet's more especially, it is true—that if their works be good, they contain within themselves all that is necessary for their being comprehended and relished." Wordsworth had his own secret—an illegitimate child in France—but it is true that we need know nothing about an author in order to enjoy his works. Surely, however, we shall enjoy them more if we know a little about his personality, if we understand not only the internal difficulties over which he had to triumph in order to produce them but how these very elements of his nature find expression in his writings. Biography adds a fourth dimension to the understanding and enjoyment of the works of genius; for, though we can enjoy a poem, a picture, or a symphony without even knowing who created it, we then enjoy it in isolation from the whole of the author's personality except its expression in that particular work of art. But when we understand his biography—and by biography I mean not merely a historical account of the facts of his life but also all that we can learn about his heredity, the workings of his nervous system, and the conflicts of his mind—we find his works enriched by being seen in perspective, in the dimension of time in which all his past has made him what he is and his creations what they are.

There is another objection also which is sometimes expressed. "What interests us about a genius," some people say, "is what is unique in him—not his neurosis or his psychosis, which is something he possesses in common with thousands of others." But it is a fallacy to suppose

The photograph of the statue of John Donne in St. Paul's Cathedral is here reproduced by kind permission of the Dean.

*An address given to the London Hospital Medical Society.

that the unique mental features of a genius exist in isolation from any abnormalities he may exhibit, for what is interesting in the neurosis or psychosis of a genius is not the features it shares with similar disorders in ordinary people but the part that it plays in his individual and therefore unique mental life. Indeed, the most important feature of any neurosis or psychosis is not what it shares with other disorders of its class but its uniqueness as an integral part of a particular personality. But I must add a word of caution. It is easy to let speculation run riot on the subject of the psychology of genius and justify oneself by the generalizations of some particular psychological theory. We shall be on firmer ground and still find plenty to interest us if we stick to descriptive psychiatry and concern ourselves only with those grosser traits of conduct, thought, and feeling which are obvious in the writings of our subjects or in the observations of their contemporaries.

Instead of generalizing about the psychopathology of authors I propose to describe in some detail a few case histories; but before I do so, and lest you should think I exaggerate the relationship between mental instability and great literature, here is a list, which is certainly not comprehensive, of some great writers who were either insane in the sense that they would to-day have been regarded as certifiable, or, though perhaps never certifiable, were cyclothymes, schizophrenics, obsessionals, psychopaths, alcoholics, or drug addicts: Beddoes, Blake, Boswell, Bunyan, Burns, Byron, Chatterton, Clare, Coleridge, Collins, Cowper, Crabbe, De Quincey, Dickens, Donne, Gray, Johnson, Lamb, Rossetti, Ruskin, Shelley, Smart, Swift, Swinburne, Tennyson, and Francis Thompson. And to show that English literature is not exceptional in this respect let me add a few from other nations: Baudelaire, Dostoievsky, Flaubert, Goethe, Gogol, Holderlin, Nietzsche, Poe, Rimbaud, Rousseau, Strindberg, Swedenborg, and Verlaine.

Death's Duellist

John Donne (1572–1631) is one of the strangest figures in English literature—the Catholic who died Dean of St. Paul's, the poetical amorist who became the author of the Holy Sonnets. His influence upon English poetry—which, according to his biographer, Edmund Gosse, was almost entirely malign—can still be traced without difficulty to-day. Dr. Johnson thought his metaphors far-fetched and at times indelicate. His eloquence as a preacher and his preoccupation with the fate of the body after death drew large crowds of fascinated hearers, and this perennial theme came so to possess him that the last events of his life seemed a drama in which he was ready at length to act the part he had so often rehearsed. For, he wrote,

> Since that I
> Must dye at last, 'tis best
> To use my selfe in jest,
> Thus by fain'd deaths to dye.

His *Devotions upon Emergent Occasions*, written during a serious illness in 1623, not only consist of characteristic reflections upon mortality but include in the headings of the chapters a summary of the stages of his disease and the conduct of the doctors. "The first alteration, the first grudging of the sickness. . . . The patient takes to his bed. The Phisician is sent for. The Phisician comes. The Phisician is afraid. The Phisician desires to have others joyned with him. The King sends his own Phisician. Upon their consultation they prescribe." Then follows the treatment—cordials and pigeons—but "the Sickness declares the infection and malignity thereof with spots. . . . I sleep not day nor night. . . . From the Bells of the Church adjoyning I am daily remembered of my buriall in the funeralls of others. Now this Bell tolling softly for another, saies to me, Thou must die." (In that chapter occurs the famous sentence, "Any man's death diminishes me, because I am involved in mankinde, And therefore never seek to know for whom the bell tolls; It tolls for thee.") But "at last, the Phisicians after a long and stormie voyage, see land." They proceed to purge, the patient recovers, but he is warned of "the fearful danger of relapsing."

Donne could never long avert his mind from the thought of the body's dissolution. It appears in his sermons on all sorts of occasions, one of the grimmest meditations on this theme being in a sermon preached at the marriage of the Earl of Bridgewater's daughter. Here is one such passage in his magnificent prose from his last sermon, preached before King Charles I. "That that Monarch, who spred over many nations alive, must in his dust lie in a corner of that sheete of lead, and there, but so long as that leade will laste, and that privat and retir'd man, that thought himselfe his owne for ever, and never came forth, must in his dust of the grave bee published, and (such are the revolutions of the graves) bee mingled with the dust of every highway and every dunghill, and swallowed in every puddle and pond: This is the most inglorious and contemptible vilification, the most deadly and peremptory nullification of man, that wee can consider."

Donne was dying when he preached this sermon, which came to be known as "Death's Duell." "Many that saw his tears and heard his faint and hollow voice," says Izaak Walton, "thought that Dr. Donne had preached his own funeral sermon."

But there was a stranger episode to come. Dr. Simeon Foxe, his physician, urged him to arrange for a monument to be erected to him in his cathedral. Donne agreed on condition that Dr. Foxe should not interfere in any way with the character or form of the memorial. Here is Walton's account of what followed:

> "A monument being resolved upon, Dr. Donne sent for a carver to make for him in wood the figure of an urn, giving him directions for the compass and height of it; and to bring with it a board of the just height of his body. These being got, then without delay a choice painter was got to be in readiness to draw his picture, which was taken as followeth:—Several charcoal fires being first made in his large study, he brought with him into the place his winding-sheet in his hand, and having put off all his clothes, had this sheet put on him, and so tied with knots at his head and feet, and his hands so placed as dead bodies are usually fitted, to be shrouded and put into their coffin or grave. Upon this urn he thus stood, with his eyes shut, and with so much of the sheet turned aside as might show his lean, pale, and death-like face. . . . In this posture he was drawn at his just height, and when the picture was finished he caused it to be set by his bedside, where it continued and became his hourly object till his death, and was then given to his dearest friend and executor, Dr. Henry King, then chief Residentiary of St. Paul's, who caused him to be thus carved in one entire piece of white marble, as it now stands in that Church."

No doubt Donne's attitude to death was in part Elizabethan, and it can to some extent be paralleled in contemporary writers, such as Webster and Sir Thomas Browne, but it was also an obsession, springing from what Gosse rightly calls "the morbid and fantastic character of his genius."

L'Enfant Terrible

Jonathan Swift (1667–1745) could claim distinction as politician, Dean of St. Patrick's, and satirist, but his satires

are remembered by many who know little about his politics and less about his theology. His satires spring from his feelings, and his emotional life was very odd, so odd indeed that it considerably puzzled his contemporaries and is still the subject of speculation to-day. In 1701 Swift, then 34, invited to live near him in Ireland two ladies, Esther Johnson, aged 20, whom he immortalized as Stella, and her older companion Rebecca Dingley. Till the death of Stella in 1728 Swift remained on terms of affectionate friendship with both of them, writing to them when he was absent letters which included messages couched in the language of the nursery. This strange relationship was complicated by the intrusion of another woman, Esther Vanhomrigh, whom Swift called Vanessa, and who fell in love with him.

The question which has been discussed ever since is, What were the relations of Swift and Stella? Swift was a single man of irreproachable morals: why did he never marry her? There seemed to his contemporaries, to Dr. Johnson, and to most people since, to be only two possible explanations: either he did marry her, but for some reason concealed the fact, or there was an external barrier to their marriage. They were, it has been suggested, uncle and niece or half-brother and half-sister. The barrier was real, but it existed in Swift's emotional life. The clue is to be found in *Gulliver's Travels*. "The greatest difficulty that occurs in analysing his character," wrote Johnson, "is to discover by what depravity of intellect he took delight in revolving ideas, from which almost every other mind shrinks with disgust. The ideas of pleasure, even when criminal, may solicit the imagination, but what has disease, deformity, and filth, upon which the thoughts can be allowed to dwell?" Swift's preoccupation with excretion is a constantly recurring theme upon which he plays some fantastic variations. His attitude to the body, and especially the female body, is equally pathological, and is magnified when the body is enlarged to the Brobdingnagian scale. Freud has a word for all this, but one does not need to be a Freudian to see that Swift was emotionally arrested at an infantile stage of development.

Perhaps the most illuminating piece of evidence for his abnormality is the speech which he puts into the mouth of Gulliver when meeting his wife and children on his return from his last voyage: "As soon as I entered the House," wrote Gulliver, "my Wife took me in her arms and kissed me; at which not having been used to the Touch of that odious Animal for so many years, I fell in a Swoon for almost an Hour. . . . During the first year I could not endure my Wife or Children in my Presence, the very smell of them was intolerable, much less could I suffer them to eat in the same Room. To this day they dare not presume to touch my Bread or drink out of the same Cup; neither was I ever able to let one of them take me by the Hand." This, it may be said, is Gulliver, not Swift, talking, but it is the imagination of Swift speaking through Gulliver, and no man who could feel so perversely about normal human relationships would be likely to marry. Swift may not have known why he felt as he did, but he had too much insight to be self-deceived. In a poem called *Cadenus and Vanessa*, in which he is Cadenus (an anagram of Decanus the Dean) and Esther Vanhomrigh is Vanessa, he writes:

> He now cou'd praise, esteem, approve,
> But understood not what was Love. . . .
> Love, hitherto a transient guest,
> Ne'er held Possession of his Breast:
> *So long attending at the Gate,*
> Disdain'd to enter in so late.

We do not know whether Stella ever challenged him in this way, but she seems to have come to accept the Platonic role he assigned to her. Swift was broken-hearted when she died. He lived on to die demented, after a period of melancholia, nearly twenty years later. There is a legend that this perversely fastidious man, who had been so revolted by the flesh, was buried in the same coffin with her. This invention was the last unconscious irony of the Yahoos.

The Great Convulsionary

I suppose that most people who possess an average man's knowledge of Samuel Johnson (1709–84) regard him as a monument of British common sense—a kind of intellectual John Bull, dogmatic, tough, and rather insensitive. This is only half the truth, the superficial half, for beneath his assured demeanour lay a torment of apprehensiveness, doubt, and misgiving which found expression in great eccentricity of behaviour.

Thomas Tyers said of Johnson, "He was to the last a convulsionary. . . . His gestures, which were a degree of St. Vitus's dance, in the street attracted the notice of the many, the stare of the vulgar, but the compassion of the better sort." Johnson's gesticulations, which gave Hogarth the first impression that he was mad, have often been described, but nowhere better than by Miss Reynolds, who speaks of "his extraordinary gestures or anticks with his hands and feet, particularly when passing over the threshold of a door. On entering Sir Joshua's house with poor Mrs. Williams, a blind lady who lived with him, he would quit her hand, or else whirl her about on the steps as he whirled and twisted about to perform his gesticulations: and as soon as he had finished, he would give a sudden spring, and make such an extensive stride over the threshold, as if he was trying for a wager how far he could stride, Mrs. Williams standing groping about outside the door, unless the servant or the mistress of the house more commonly took hold of her hand to conduct her in, leaving Dr. Johnson to perform at the Parlour Door much the same exercises over again. . . . But the manœuvre that used the most particularly to engage the attention of the company was his stretching out his arm with a full cup of tea in his hand, in every direction often to the great annoyance of the person who sat next to him, indeed to the imminent danger of their cloaths, perhaps of a Lady's Court dress; sometimes he would twist himself round with his face close to the back of his chair and finish his cup of tea, breathing very hard, as if making a laborious effort to accomplish it."

According to Miss Reynolds he carried out similar manœuvres in the street while his companions went ahead to wait for him, and caused a crowd to collect in Twickenham Meadows by his violent see-sawing over Grotius's *De Veritate Religionis*. Boswell has described his rolling gait and his habits of whistling and blowing and counting his steps in order to reach a certain point with his right or his left foot; and from Whyte we learn of his practice of touching posts in the street and going back when he had missed one to repair the omission.

Johnson's contemporaries were divided into two schools of thought on the question of the nature of his malady. Boswell, like Thomas Tyers, thought it was a physical disease, St. Vitus's dance, and believed he was confirmed in his opinion by Sydenham's own description, which he quotes. Sir Joshua Reynolds, however, with the acute observation of an artist, noted that Dr. Johnson's "strange antic gestures" accompanied his reveries and that he never exhibited them when engaged in conversation. He thought,

therefore, that the gesticulations were "improperly called convulsions which implied involuntary cortortions." Sir Joshua also made an observation of profound psychological insight when he said that Johnson's actions always appeared to him as if they meant to reprobate some part of his past conduct. It is quite clear to-day that Reynolds was right and that Johnson's movements, although involuntary in the sense that they were not under his control, were not, like St. Vitus's dance, due to organic disease of the brain but were of psychological origin. He knew this himself, for when a young girl, a Miss Hunter, asked him, with some temerity, "Pray, Dr. Johnson, why do you make such strange gestures?" he replied, "From bad habit."

Fears and Apprehensions

This view of the nature of his gesticulations is confirmed by the fact that symptoms of a similar kind occurred in the realm of thought and feeling. Here involuntary fears and apprehensions took the place of involuntary movements. It is impossible to agree with Raleigh that Johnson's fear of death was only a fear of Boswell on death. It was clearly an obsession which could be evoked not only by Boswell's inquiries but by the sight of bones or of a memorial urn, and this is the probable explanation of the outburst of almost hysterical laughter which was excited by Langton's making his will and which so puzzled Boswell. Another obsession was his fear of insanity, which remained with him from his youth, when he consulted Dr. Swinfen and received an answer "importing that the symptoms indicated a future privation of reason," to his old age, when at the time of his stroke he prayed God that however he might afflict his body he would spare his understanding —a prayer which, that he might try the integrity of his faculties, he made in Latin verse.

He was also obsessed with a sense of guilt. As Mrs. Thrale put it, his "daily terror lest he had not done enough originated in piety, but ended in little less than disease. . . . He . . . filled his imagination with fears that he should never obtain forgiveness for omission of duty and criminal waste of time."

Doubtless it was these fears of insanity, death, and damnation that racked his mind when he was alone and rendered solitude so distasteful and indeed distressing to him. "I lie down," he said, "that my acquaintance may sleep; but I lie down to endure oppressive misery; and soon rise again to pass the night in anxiety and pain." Nothing conveys so moving a picture of his lonely and distracted spirit as Murphy's account of how "for many years, when he was not disposed to enter into the conversation going forward, who ever sat near his chair might hear him repeating, from Shakespeare,

> "Ay, but to die, and go we know not where:
> To lie in cold obstruction, and to rot;
> This sensible warm motion to become
> A kneaded clod; and the delighted spirit
> To bathe in fiery floods."

This "morbid melancholy," which Johnson himself believed to be inherent in his constitution, pervaded his thought and made him, in his own words, "mad all his life, at least not sober." I can find no better or nobler expression of it than the last words of the last *Idler* which he called the "Horrour of the Last." In the course of this essay he says: "This secret horror of the last is inseparable from a thinking being, whose life is limited, and to whom death is dreadful." And he concludes: "I hope that my readers are already disposed to view every incident with seriousness, and improve it by meditation; and that, when they see this series of trifles brought to a conclusion, they will consider that, by outliving the Idler they have passed weeks, months, and years, which are now no longer in their power; and that an end must in time be put to everything great as to everything little; that to life must come its last hour, and to this system of being its last day, the hour at which probation ceases, and repentance will be vain, the day in which every work of the hand and imagination of the heart shall be brought to judgement, and an everlasting futurity shall be determined by the past."

Thus we can trace Johnson's morbidity at three levels—his compulsive gestures, his obsessive fears and sense of guilt, and his insistence on the evils of life, its transitoriness, and the ultimate and inescapable judgment, which sounds a note of doom in so many of his writings. Like many obsessionals he was subject to periods of severe depression, the worst of which occurred when he was between 50 and 60. His prayers and meditations in the first half of his sixth decade reveal his struggles with a deepening gloom Dr. Adams told Boswell that he "found him in a deplorable state, sighing, groaning, talking to himself and restlessly walking from room to room." Mrs. Thrale says that he did not stir out of his room for weeks or even months, till she and her husband carried him off to Streatham.

Johnson's mental disorder was clearly compatible with the greatest intellectual powers and with considerable, if sporadic, energy. He found that he lost his symptoms partially or completely when his attention was fully occupied with something else; hence his eagerness for company and reluctance to go to bed. His discovery of the value of distraction is illustrated by one of Mrs. Thrale's anecdotes "When Mr. Johnson felt his fancy, or fancied he felt it, disordered, his constant recurrence was to the study of arithmetic; and one day that he was totally confined to his chamber and I enquired what he had been doing to divert himself; he showed me a calculation which I could scarce be made to understand, so vast was the plan of it and so very intricate were the figures; no other indeed than that the national debt, computing it at one hundred and eighty millions sterling, would, if converted into silver, serve to make a meridian of that metal, I forget how broad, for the globe of the whole earth, the real globe." Dr. Johnson would have had no difficulty in making our present national debt reach to the moon.

He prescribed the study of algebra for a fellow obsessional who consulted him about his scruples, though he did not show him much sympathy. This was a man who was obsessed with guilt at having taken his employer's paper and pack-thread even with his permission. "I would advise you, Sir, to study algebra, if you are not an adept already in it: your head would get less muddy, and you will leave off tormenting your neighbours about paper and pack-thread, while we all live together in a world that is bursting with sin and sorrow."

To trace the effects of the obsessional state upon the temperament is beyond my present scope, but I would draw attention to one characteristic trait, the sufferer's attitude to the past. More than most men, the obsessional is in bondage to the past; for what is an obsession but a past idea of which he cannot rid himself? In Johnson's own words, "an everlasting futurity" is "determined by the past." The past is both inescapable and unchangeable: for Johnson, therefore, guilt endured, and salvation must ever be in doubt. This perverse vitality of his past is well illustrated by the remarkable episode at Uttoxeter market when in old age he stood bare-headed in the rain for a

considerable time to expiate an act of disobedience to his father in his youth. It provides a basis too for Sir Joshua Reynolds's remarkable observation that the gesticulations appeared as if they were meant to reprobate his past conduct.

This picture of Johnson's mental suffering is of course only one aspect of him, but we cannot fully appreciate the light without the shade, nor his achievements without knowing the difficulties he had to contend with. If I am right, the light and the shade are complementary. It was to find escape from his private gloom that he sought the Club and the drawing-room. It was despite nights passed in "oppressive misery" that, as Fanny Burney said, he had "more fun and comical humour and love of nonsense about him than almost anybody I ever saw"; and it was from an overpowering depression and lethargy that he roused himself to accomplish the *Dictionary* and the *Lives of the Poets*.

"Bozzy"

I need say little about James Boswell (1740–95), because his psychology has recently been so admirably summed up by Dr. Douglas Hubble.* Boswell was a cyclothyme, subject to the characteristic alternations of elation and depression, and no doubt it was this inherited psychopathic trait which brought his brother and his daughter to actual insanity. Dr. Hubble has traced the influence of external factors upon his variations of mood, and, in particular, has stressed the importance of his relation with his father. "Whenever James was in the company of Auchinleck the image of himself dwindled until it was no larger than a small boy, beloved and indulged by his mother, but intimidated by the stern and sarcastic tongue of Alexander Boswell." The effect of this conflict was to send Boswell in search of a father substitute who should be great and good, and one such was Johnson. Dr. Hubble concludes that "those who are tempted to take sides in this predetermined struggle between father and son will refrain when they recall that the direct outcome of the conflict was the immortal biography of Samuel Johnson."

One might perhaps go a little further and suggest that if Boswell was in search of a father, Johnson was looking for a son, and the psychological miracle was that these two great eccentrics exactly suited one another. Boswell had all the cyclothyme's vivacity, spontaneity, and warmth of feeling which in Johnson's character were absent or overwhelmingly inhibited. But these qualities alone would have been intolerable to Johnson: they were balanced and redeemed by Boswell's high intelligence and literary gifts. There may have been deeper emotional factors; but here, surely, is a sufficient psychological basis for that unique partnership through which each immortalized the other. Finally, I cannot refrain from quoting one other comment by Dr. Hubble: "Boswell was a drunkard. Boswell wrote two masterpieces of English literature—the one unsurpassed and the other unsurpassable. Boswell was a lecher. Boswell was unusually humane and generous. Boswell was a buffoon. Boswell was the friend of Johnson, of Burke, of Reynolds, and of Paoli—all of whom loved him. Those who find such contrasts irreconcilable have long lost the power of self-examination."

The Flea that Became an Eagle

The eighteenth century produced several mad poets: Collins, Smart, Cowper, and Clare—who just comes into it—all became insane. Christopher Smart (1722–71) is unique in that his poetry was improved by his madness. Dr. Johnson, when asked whether Derrick or Smart was the better poet, replied: "Sir, there is no settling the point of precedency between a louse and a flea." Except for a few lines such as his verses *On an Eagle Confined in a College Court*, Smart wrote nothing before or after his mental breakdown that could be quoted against Johnson's dictum, and, however he may have appeared to himself, nobody else pictured him soaring among the mountaintops of poetry. He became insane, and the miracle that so much puzzled Browning occurred—he wrote *A Song to David*. The flea for a time became an eagle.

It is from Johnson that we learn much of what is known about Smart's madness as it appeared to others, and Boswell records the following conversation between Johnson and Burney. "Burney: 'How does poor Smart do, Sir; is he likely to recover?' Johnson: 'It seems as if his mind had ceased to struggle with the disease; for he grows fat upon it.' Burney: 'Perhaps, Sir, that may be from want of exercise.' Johnson: 'No, Sir; he has partly as much exercise as he used to have, for he digs in the garden. Indeed, before his confinement, he used for exercise to walk to the ale-house, but he was *carried* back again. I did not think he ought to be shut up. His infirmities were not noxious to society. He insisted on people praying with him; and I'd as lief pray with Kit Smart as anyone else. Another charge was that he did not love clean linen; and I have no passion for it.'" Smart was a cyclothyme: he himself said, "I have a greater compass both of mirth and melancholy than another." His disorder is easy to diagnose from his poem *Jubilate Agno*—"Rejoice in the Lamb"—which was written in a madhouse and which shows all the features of maniacal excitement. In the *Jubilate* the spate of ideas sweeps away both sound and sense, and the process of mental association occurs so readily as to be poetically meaningless. The mere sound or clang of words is sufficient to link them together, or the arbitrary apposition of a person and an animal, bird or plant acquires for the poet a spurious significance.

A Song to David, on the other hand, evidently written at the end of Smart's confinement when he had almost recovered, is a true poem, though even here the mood of extreme elation and a certain looseness of the texture of ideas show that the mental storm had not quite subsided. But the after-swell gave him a heightened emotional tension, an associative aptness and a feeling for words that he had never possessed before.

Then he recovered. The eagle became a flea again; or, it would be truer to say, Pegasus lost his wings and reverted to a nag, and Smart's verse ambled along at its habitual jog-trot for the few years of his life that remained.

Bill Sikes and Nancy

Much might be said about the relationship between the personal conflicts of Charles Dickens (1812–70) and his writings, but I can now deal with only two aspects of his temperament—his cyclothymia and his sado-masochism, both stressed by Mr. Edmund Wilson in his study of Dickens's psychology.* Dickens was undoubtedly a cyclothyme. His moods of depression do not seem to have been very frequent, but they were quite characteristic. His son, Sir Henry Dickens, speaks of his father's "heavy moods of deep depression, of intense nervous irritability, when he was silent and oppressed." Dickens himself more than once describes his feelings in his letters. "I am sick, giddy and capriciously despondent," he wrote to Forster; "I have bad nights, am full of disquietude and anxiety." Six

*The Wound and the Bow, 1941.

months later he told Georgina Hogarth, "My wretchedness just now is inconceivable." While staying at Bonchurch in 1849, writing of himself as "the Patient," he said: "If he have any thing to do requiring thought and attention this overpowers him to such a degree he can only do it in snatches." He speaks of "extreme depression of mind and a disposition to shed tears from morning to night . . . a dull stupid languor. He has no purpose, power or object in existence whatever." The obverse of these phases of depression was his prevailing mood of elation, which gave him his enormous gusto and from which he derived his energy, which at first was canalized into his prolific inventiveness, in later life feverishly squandered in his readings, and always overflowing into long walks, parties, and amateur theatricals. It was his cyclothymic temperament, too, that enhanced his great sensibility, which made him respond with far more feeling than the average man both to his own experiences and to the sufferings of others. This sensibility was in turn heightened by the vividness of his memory.

Blent with Dickens's cyclothymia was his sado-masochism, which has been analysed especially by Mr. Edmund Wilson. Perhaps having been brought up to regard Dickens as a monument of Victorian respectability and normality, most of us have never achieved sufficient detachment to appreciate this element in him. Though more obvious in some than in others, it runs like a scarlet thread through all his writings. Here, for example, are the instances of violence that occur in one novel, *A Tale of Two Cities*. Dr. Manette spends years in the Bastille; Charles Darnay is on trial for his life; Jerry Cruncher pursues the grim trade of a resurrectionist; the Marquis de St. Evremonde carelessly runs over and kills a child, and is himself murdered in revenge. His brother has raped the sister of Mme. Defarge and killed her brother, as a result of which their father died of a broken heart. Scenes of revolutionary violence dominate the story; the Bastille is stormed and the guillotine falls incessantly. Finally, Mme. Defarge is shot and killed by Miss Pross, and Sydney Carton and the little sempstress, both innocent, are executed together. There is almost as much violence in *Barnaby Rudge*, in which the Gordon Riots take the place of the French Revolution and the sacking of Newgate corresponds to the storming of the Bastille. In this tale execution is personified in Dennis the hangman. Mr. Harold Nicolson has pointed out how often beheading figures in Sam Weller's jokes, and Mr. Edmund Wilson has stressed the large part played by prisons in Dickens's stories. A more personal and refined kind of cruelty is exemplified by the behaviour of the Murdstones to David Copperfield, Squeers to the boys at Dotheboys Hall, and Quilp to his wife.

This emphasis upon violence and cruelty in the novels was only the reflection of a similar preoccupation in Dickens's own life. One of his favourite recreations in Paris was to visit the Morgue. He went to public executions at home and abroad, wrote to *The Times* to protest at the spectacle. "Holy," when he travelled he made a point of visiting the prisons, in his consuming when he went to the Zoo he was so fascinated by the spectacle of the snakes being fed with live rabbits, that he could not drive it from his mind for a long time. Where animated by the same animals and birds to call psychosomatic disorders. Dickens's death was so much the outcome of what it is fashionable to call psychosomatic disorders that his latest biographer, Mr. Hesketh Pearson, some justice describes it as *felo de se*. Soon after he began to get warnings of circulatory disorders of which he carried on an American tour with characteristic energy. Back in this country in the following year, he decided to add to his repertoire the episode in *Oliver Twist* in which Bill Sikes murders Nancy. Probably his cerebral arteriosclerosis was already weakening his control over his feelings and allowing his sado-masochism more overt expression. It was still projected into the world of his imagination, but he was identifying himself with his impulses more closely than in his books, for now he was acting the scene and himself impersonating both the murderer and his victim. Many of his friends who saw him do it privately were horrified, and Forster tried to dissuade him from it; but he toured the country imparting, says Mr. Pearson, "to the murder scene such a sense of horror that the audience were semi-paralysed, and sat with blanched faces in frozen silence." It was noted that these readings put his pulse up to 120. Before long he developed a sense of deadness in the left side of the body, and the readings were abandoned. The next year he died of a stroke at the age of 58.

Conflict and Creativeness

How far do the characters of the strange beings whose lives are here briefly considered help us to disentangle "that subtile knot which makes us man?" What part did their mental abnormalities play in their creative genius? What sort of poet and preacher would Donne have been without his death-wish? Would an emotionally mature Swift have written *Gulliver* or any of his satires? Is there any relation between Johnson's contortions and his common sense, his obsessions and his verbal precision; and would a stable Boswell ever have immortalized him? How much of *Dickens would have been left without his hypomanic* energy and his preoccupation with suffering? Clearly, no man is a great creative artist because he is a psychopath. but our subjects surely show that, given the necessary qualities of mind, more than one process which the psychiatrist calls pathological may be an essential element in the virtues of genius—and perhaps of the rest of us. But what in the mental sphere is the meaning of normal and pathological? Is normality more than a statistical myth? The vast appeal of many creative artists, even the abnormals like Donne, Swift, and Dickens, is to readers whose feelings have something in common with their own. The great artist is a medium through whom our own emotions are expressed, intensified, and illuminated, with results that depend upon their nature and upon our reaction to this heightened experience.

There is a quantitative factor in this which is worth considering. The genius of literature has higher intelligence. more intense and more highly differentiated feelings, a better memory, and a greater capacity for words than the rest of us, and these presumably depend upon a quantitatively richer organization of his nervous system. He also has a dynamic quality which often seems to raise even his madness to a higher power. His creativeness is the resultant of his inner tensions, in which, if he is to create at all, his integrative forces must at least from time to time balance his conflicts and disruptive impulses. Thus for many a genius life is an agonizing struggle from which he may emerge victorious, but which often ends in his destruction by his daimon, the inner fate of the Greeks. Where is man's daimon to-day? Is it the diencephalon, the site of the emotions, or the integrating power of the frontal lobe which, as Dr. Freeman recently said, "is necessary for creativeness as well as for neurosis"? Art and character spring from the relations between these two. Are they not perhaps the two winged horses of the soul, pictured by Plato in his parable being driven by the charioteer he rashly named Reason?

THE FATE OF THE FORESKIN

A STUDY OF CIRCUMCISION

BY

DOUGLAS GAIRDNER, D.M., M.R.C.P.

Consultant Paediatrician, United Cambridge Hospitals

It is a curious fact that one of the operations most commonly performed in this country is also accorded the least critical consideration. In order to decide whether a child's foreskin should be ablated the normal anatomy and function of the structure at different ages should be understood: the danger of conserving the foreskin must then be weighed against the hazards of the operation, the mortality and after-effects of which must be known. Though tens of thousands of infants are circumcised each year in this country, nowhere are these essential data assembled. The intention of this paper is to marshal the facts required by those concerned with deciding the fate of the child's foreskin.

Origins of Circumcision

Male circumcision, often associated with analogous sexual mutilations of the female such as clitoric circumcision and infibulation, is practised over a wide area of the world by some one-sixth of its population. Over the Near East, patchily throughout tribal Africa, amongst the Moslem peoples of India and of South-East Asia, and amongst the Australasian aborigines circumcision has been regularly practised for as long as we can tell. Many of the natives that Columbus found inhabiting the American continent were circumcised. The earliest Egyptian mummies (2300 B.C.) were circumcised, and wall paintings to be seen in Egypt show that it was customary several thousand years earlier still.

According to Elliot Smith circumcision is one of the characteristic features of a "heliolithic" culture which, some 15,000 years ago, spread out over much of the world; others believe that the practice must have arisen independently among different peoples. In spite of the enormous literature on the subject (well summarized in Hastings's *Encyclopaedia of Religion and Ethics*), we remain profoundly ignorant of the origins and significance of this presumably sacrificial rite. The age at which boys are circumcised varies widely in different races, from the Mosaic practice of circumcising at about the eighth day, to the custom in many African tribes of making circumcision part of an initiation ceremony near the age of puberty. Circumcision was introduced into Roman Europe with Christianity; little is known about its status in mediaeval Europe, but it was probably customary only amongst adherents of the Jewish faith until, with the rise of modern surgery in the nineteenth century, its status changed from a religious rite to that of a common surgical procedure.

Development of the Prepuce

The prepuce appears in the foetus at eight weeks as a ring of thickened epidermis (Fig. 1, a) which grows forwards over the base of the glans penis (Fig. 1, b). It grows more rapidly on the upper surface than the lower, and so leaves the inferior aspect of the preputial ring deficient (Hunter, 1935). At 12 weeks the urethra still opens on the inferior aspect of the shaft of the penis and the terminal part of the urethra has yet to be constructed. Arrest at this stage produces the glandular type of hypospadias, with the "hooded" prepuce only partially covering the glans.

From the inferior aspect of the glans a pair of outgrowths are pushed out and meet (the sulcus on the under aspect of the glans marks their fusion), so enclosing a tube which, becoming continuous with the existing urethra, advances the meatus to its final site. These outgrowths from the glans carry with them the prepuce on each side (Fig. 1, c), thus completing the prepuce inferiorly and forming the frenulum.

By 16 weeks the prepuce has grown forwards to the tip of the glans. At this stage (Fig. 1, d) the epidermis of the deep surface of the prepuce is continuous with the epidermis covering the glans, both consisting of squamous epithelium. By a process of desquamation the preputial space is now formed in the following manner (Deibert, 1933). In places the squamous cells arrange themselves in whorls, forming epithelial cell nests. The centres of these degenerate, so forming a series of spaces (Fig. 1, e); these, as they increase in size, link up until finally a continuous preputial space is formed.

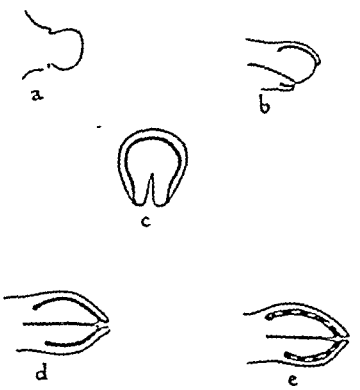

FIG. 1.—Development of prepuce. (*a*) Eight weeks; (*b*) sagittal section and (*c*) coronal section, 12 weeks; (*d*) 16 weeks; (*e*) at about term, compare Fig. 3.

The stage of development which has been reached by the time the child is born varies greatly. Figs. 2, 3, and 4 show sections of the penis in three full-term newborn infants; in Fig. 2 separation of the prepuce has not yet begun; in Fig. 3 separation is partial; in Fig. 4 separation is complete, though this, as will be shown, is uncommon at birth.

Anatomy of the Prepuce

The Younger Child.—The prepuce is still in the course of developing at the time of birth, and the fact that its separation is usually still incomplete renders the normal prepuce of the newborn non-retractable. (It will be seen that preputial "adhesions" is an inapposite term to apply to the incompletely separated prepuce, suggesting as it does that the prepuce and glans were formerly separate structures.) The age at which complete separation of the prepuce with full retractability spontaneously occurs is shown in Fig. 5, which has been constructed from observations of the prepuce in a series of 100 newborns and about 200 boys of varying ages up to 5 years. Of the newborns, 4% had a fully retractable prepuce, in 54% the glans could be uncovered enough to reveal the external meatus, and in the remaining 42% even the tip of the glans could not be uncovered. Of the older group 10% had been circumcised and a few had at some time had their prepuce "stretched"; the figures from which the diagram is constructed are therefore not precise, but they indicate with sufficient accuracy that the prepuce is *non-retractable* in four out of five normal males of 6 months and in half of normal males of 1 year. By 2 years about 20% and by 3 years about 10% of boys still have a non-retractable prepuce.

The fact that at these ages non-retractability depends upon incomplete separation of the prepuce can be easily demonstrated by running a probe round the preputial space, gently completing its continuity. It will then be found

that, although the prepuce is often somewhat tighter than in the adult, it is not tight enough to prevent retraction. This test was applied to a series of 54 boys aged from 2 months to 3 years who had been referred to hospital for circumcision, generally with a diagnosis of phimosis. In

FIG. 2.—Separation of prepuce has not begun and there is as yet no preputial space.

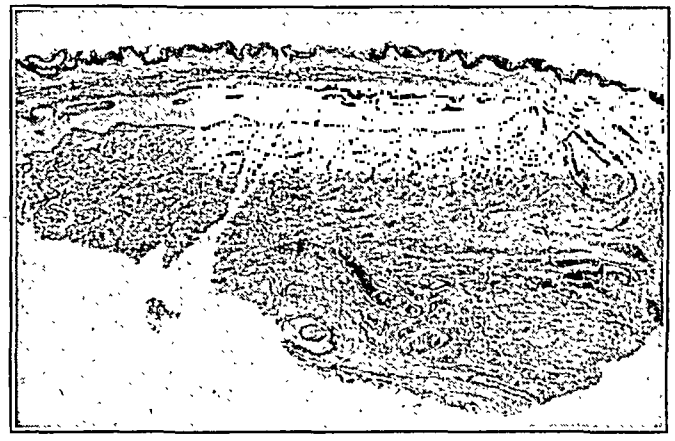

FIG. 3.—Foci of desquamation leading to partial separation of prepuce.

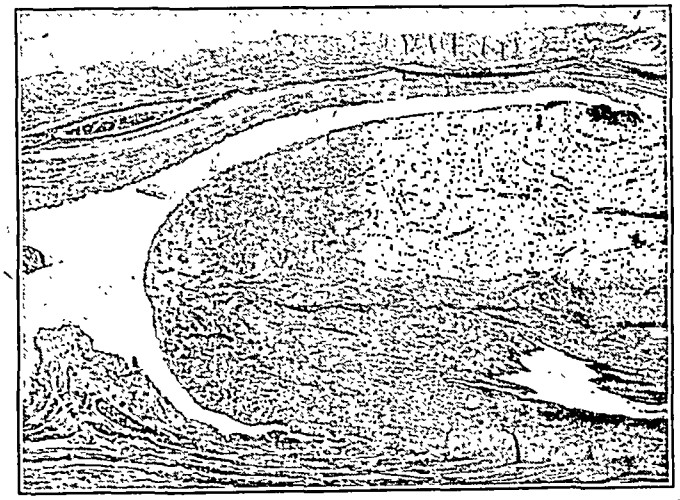

FIG. 4.—Separation of prepuce completed to form fully developed preputial space.

53 of the 54 the prepuce became easily retractable by this simple manipulation; in one 5-months-old infant this manœuvre failed because preputial separation had not advanced far enough to enable manipulation to complete the process. Although in this way the prepuce of nearly every infant can be rendered retractable, the procedure, necessarily involving the tearing apart of two as yet incompletely separated surfaces, causes some bleeding and opens the way to possible infection. For these reasons it is inadvisable as a routine procedure.

Prepuce of the Older Child.—Of 200 uncircumcised boys aged 5–13 years from three different schools, 6% had a non-retractable prepuce; in a further 14% the prepuce could be only partially retracted. In the majority of boys in this age group non-retractability depends upon the persistence of a few strands of tissue between prepuce and glans, so that minimal force is required to achieve retractability. In this age group, however, retraction of a hitherto unretracted prepuce discovers inspissated smegma, which, in contrast to that found in the younger child, is in some cases malodorous. This, together with the facts discussed under penile cancer, indicates that a different view ought to be taken of the non-retractable prepuce in the child over about 5 years, and that, whereas a non-retractable prepuce in the young child should be accepted with equanimity as normal, after about 3 years of age steps should be taken to render the prepuce of all boys retractable and capable of being kept clean.

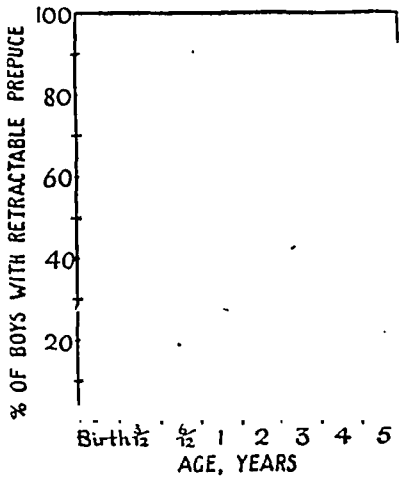

FIG. 5.—Proportion of boys of varying ages from birth to 5 years, in whom the prepuce has spontaneously become retractable. Note that it is uncommon for this to occur in the first six months

Function of the Prepuce

It is often stated that the prepuce is a vestigial structure devoid of function. However, it seems to be no accident that during the years when the child is incontinent the glans is completely clothed by the prepuce, for, deprived of this protection, the glans becomes susceptible to injury from contact with sodden clothes or napkin. Meatal ulcer is almost confined to circumcised male infants, and is only occasionally seen in the uncircumcised child when the prepuce happens to be unusually lax and the glans consequently exposed (Freud, 1947).

Incidence of Circumcision

Amongst the Western nations the circumcision of infants is a common practice only with the English-speaking peoples. It is, for the most part, not the custom in continental Europe or Scandinavia, or in South America. In England the collected data of various colleagues* who have kindly made observations on infants, school-children, and university students reveal wide variations as between different districts and between different social classes. For

*Dr. H. P. Broda, assistant school M.O., Cambridge; Dr. Eileen Brereton, assistant school M.O., Cambridgeshire; Drs. F. J. W. Miller and S. D. Court, Child Health Department, King's College, Newcastle-upon-Tyne; Dr. Margaret Patterson, assistant M.O.H., Cambridge; Sir Alan Rook, senior health officer, Cambridge University; Dr. R. E. Smith, medical officer to Rugby School. It is a pleasure to record my thanks to all these colleagues for their ready co-operation and many painstaking observations, and for generously allowing me to quote their findings.

instance, in Newcastle-upon-Tyne 12% of 500 male infants aged 12 months were circumcised; in Cambridge the comparable figure was 31% of 89 male infants aged 6 to 12 months. Boys coming from the upper classes are more often circumcised, 67% of 81 13-year-old boys entering a public school had been circumcised, whereas only 50% of 154 boys aged 5 to 14 in primary and secondary schools in the rural districts of Cambridgeshire, and 30% of 141 boys aged 5 to 11 in primary schools in the town of Cambridge, had been circumcised. The influence of social class is shown also by some figures analysed by Sir Alan Rook from a group of university students. Whereas 84% of 73 students coming from the best-known public schools had been circumcised, this was so of only 50% of 174 coming from grammar or secondary schools. Either the boys of well-to-do parents are suffering circumcision much too often, or those of poorer parents not often enough.

In view of the wide difference in the incidence of circumcised males in different parts of the country, it is difficult to give an average figure for the whole country. A conservative estimate of 20%, which is above the rate for Newcastle-upon-Tyne but well below that for all the other groups quoted, would mean that the number of circumcisions performed on children in England and Wales is of the order of 90,000 annually.

Mortality and Sequelae of Circumcision

Circumcision, like any other operation, is subject to the risks of haemorrhage and sepsis, and, where a general anaesthetic is employed, to the risk of anaesthetic death. The number of deaths presumed to be due to these causes is shown in the accompanying Table. The Registrar-General groups circumcision and phimosis together, but in view of the fact that "phimosis," as the term is commonly applied to infants, is physiological (see below) it is probable that the great majority of these deaths were attributable to operation rather than to any pathological condition necessitating operation.

Table Showing Deaths in Children Attributed to Circumcision or Phimosis in England and Wales

	Under 1 Year	1–4 Years	Total, Under 5 Years
1942	12	4	16
1943	10	7	17
1944	10	6	16
1945	15	2	17
1946	16	3	19
1947	9	1	10

About 16 deaths in children under 5 years occur each year from circumcision. In most of the fatalities which have come to my notice death has occurred for no apparent reason under anaesthesia, but haemorrhage and infection have sometimes proved fatal.

Haemorrhage is not uncommon after circumcision. F. J. W. Miller and S. D. Court (1949, personal communication), who followed 1,000 infants in Newcastle-upon-Tyne for their first year, found that 58 were circumcised, and two of these bled sufficiently to require blood transfusion. In my own experience about two out of every 100 children circumcised as hospital out-patients will be admitted on account of haemorrhage or other untoward event. Blood losses in the first year are particularly apt to lead to anaemia, and several infants have been seen with severe iron-deficiency anaemia following haemorrhages after circumcision.

Reference has already been made to meatal ulcer, which, in so far as it is so much more frequent in circumcised male infants, should be counted a sequel of the operation.

Pathological Conditions of Prepuce for which Circumcision is Performed

The surprising variety of reasons why different doctors advise circumcision and other operations and manipulations on the prepuce can be found described in the long correspondence on the subject which ran in the *British Medical Journal* from August to November, 1935. Circumcision is sometimes undertaken in order to cure existing pathological conditions, sometimes in order to prevent various diseases from occurring at a much later date.

Phimosis

Since in the newborn infant the prepuce is nearly always non-retractable, remaining so generally for much of the first year at least, and since this normal non-retractability is not due to tightness of the prepuce relative to the glans but to incomplete separation of these two structures, it follows that phimosis (which implies a pathological constriction of the prepuce) cannot properly be applied to the infant. Further, the commonly performed manipulation known as "stretching the foreskin" by forcibly opening sinus forceps inserted in the preputial orifice cannot be justified on anatomical grounds, besides being painful and traumatizing. In spite of the fact that the preputial orifice often appears minute—the so-called pin-hole meatus—its effective lumen, when tested by noting whether or not a good stream of urine is passed, is almost invariably found to be adequate.

Infants with umbilical or inguinal hernia are particularly liable to suffer circumcision on account of "phimosis," but if this simple test is applied, rarely will any obstruction to the urinary flow be found present. Occasionally the preputial orifice is imperfectly related to the external meatus, so that the urinary stream balloons out the subpreputial space; this can be easily remedied by gently separating the prepuce from the glans in the region of the meatus by means of a probe. True phimosis causing urinary obstruction has been described (Campbell, 1948), but must be exceedingly rare: in the cases I have seen in which this diagnosis has been made, simple separation of the prepuce has shown that there was no constriction of the preputial orifice.

Through ignorance of the anatomy of the prepuce in infancy, mothers and nurses are often instructed to draw the child's foreskin back regularly, on the supposition that stretching of the foreskin is what is required. I have on three occasions seen young boys with a paraphimosis caused by mothers or nurses who have obediently carried out such instructions; for, although the size of the prepuce does allow the glans to be delivered, the fit is often a close one and slight swelling of the glans, such as may result from forceful efforts at retraction, may make its reduction difficult.

Balanitis and Posthitis

Inflammation of the glans is uncommon in childhood when the prepuce is performing its protective function. Posthitis—inflammation of the prepuce—is commoner, and it occurs in two forms. One form is a cellulitis of the prepuce; this responds well to chemotherapy and does not seem to have any tendency to recur; hence it is questionable whether circumcision is indicated. More often inflammation of the prepuce is part of an ammonia dermatitis affecting the napkin area. The nature of this condition was firmly established by Cooke in 1921, but is still not universally known. The urea-splitting *Bact. ammoniagenes* (derived from faecal flora) acts upon the urea in the urine and liberates ammonia. This irritates the skin, which becomes peculiarly thickened, while superficial desquamation produces a silvery sheen on the skin as if it were covered with a film of tissue paper. Such appearances are diagnostic of ammonia dermatitis, and inquiry will confirm that the napkins, particularly those left on through the longer night interval, smell powerfully of ammonia. Treatment consists in impregnating the napkins with a mild antiseptic inhibiting the growth of the urea-splitting organisms. For this purpose boric acid powder sprinkled over the napkins, or a rinse of 1 in 4,000 mercuric chloride or of the recently

introduced non-toxic substance "diaparene" (Benson *et al.*, 1949), are gratifyingly effective.

When involved in an ammonia dermatitis the prepuce shows the characteristic thickening of the skin, and this is often labelled a "redundant prepuce"—another misnomer which may serve as a reason for circumcision. The importance of recognizing ammonia dermatitis lies in the danger that if circumcision is performed the delicate glans, deprived of its proper protection, is particularly apt to share in the inflammation and to develop a meatal ulcer. Once formed, a meatal ulcer is often most difficult to cure.

Enuresis

A number of symptoms of obscure cause, such as enuresis, masturbation, habit spasm, night terrors, or even convulsions, have from time to time been attributed to phimosis, and circumcision has been advised. No evidence exists that a prepuce whose only fault is that it has not yet developed retractability can cause such symptoms.

It may be apposite at this stage to quote the reasons given by the mother for desiring her child's circumcision in a series of 54 infants referred to hospital by a doctor. In 39 infants the reason was a symptomless "phimosis," found on routine inspection by doctor, nurse, mother, or neighbour. In nine cases it was said that "he cries when he wets": five of these proved to be due to ammonia dermatitis; closer questioning of the others revealed either no connexion between when the baby cried and when he urinated, or merely that crying often started micturition. In three cases the foreskin was judged to be too long or redundant, and in a further three the reason was even more frankly cosmetic ("it looks funny") or was intangible ("we believe in it"). As has been stated earlier, in all except one of this group of 54 infants, phimosis was disproved, in so far as gentle manipulation enabled the prepuce to be retracted.

Conditions Prevented by Circumcision

Universal circumcision of male infants has been urged as a means of preventing the later development of a variety of conditions—paraphimosis, venereal diseases, penile cancer, and cervical cancer of women

Paraphimosis

Some idea of the importance of paraphimosis can be gained from figures from the Royal Victoria Infirmary, Newcastle-upon-Tyne, a hospital serving a large population in which, as has been mentioned, infants are circumcised less often than in the country generally. In the children's wards paraphimosis accounts for about seven out of a total of 800 male child admissions each year (0.9%): an appreciable number of these are found to be the result of the mother's obeying misguided instructions to retract her infant's prepuce forcibly. In the adult wards it accounts for about 10 out of a total of 5,000 male surgical admissions (0.1%), so that paraphimosis scarcely constitutes an important hazard to the uncircumcised male.

Venereal Disease

Although there is a common belief that the circumcised man runs a lessened risk of venereal infection, particularly syphilitic, there are few figures to support this. Lloyd and Lloyd (1934), who reviewed the published evidence and analysed their own figures, concluded that circumcision did not diminish the chance of a syphilitic chancre. Schrek and Lenowitz (1947) found that hospital patients gave a history of venereal disease equally often whether circumcised or not. Wilson (1947) has published figures showing that, of the men attending a Canadian Army venereal disease centre, the proportion of uncircumcised soldiers (77%) was higher than in the Canadian Army generally (52%), and concluded that the uncircumcised soldier is more prone to venereal infection. It may be, however, that since circumcision of infants is *de rigueur* in Canada, the uncircumcised man will tend to come from a lower social grade and thus to be more likely to expose himself to infection. The evidence seems scarcely to warrant universal circumcision as a prophylactic against venereal infection.

Penile Cancer

This subject merits careful appraisal, for it alone of the medical reasons commonly advanced for the universal circumcision of infants is capable of withstanding critical scrutiny. In England and Wales deaths from penile cancer number about 150 a year. The relation between this disease and antecedent circumcision has recently been reviewed by Kennaway (1947). All observers agree that circumcision in the first five years of life protects absolutely from penile cancer, and this applies not only to one group such as the Jewish but equally to the mixed races of the U.S.A. The reason for this preventive effect of early circumcision is not known: it is not due to removal of the cancer-bearing area since the usual site of penile cancer, the sulcus behind the glans, is retained. If it is due to retained smegma or its decomposition products being carcinogenic, this effect must be of startling potency, since circumcision after the fifth year fails to prevent cancer occurring several decades later.

A clue to the problem may lie in the exceptionally low hygienic standards of patients with penile cancer, which has struck several observers. Dean (1935), reviewing 120 cases, writes: "Men with penis cancers gave the impression of being less intelligent, as a class, than other cancer patients. Not only had the majority ignored for long periods the precancerous state of physical annoyance, filth, and odoriferous discharges but also it was not unusual for many to delay seeking advice until a large part of the penis had become affected with an ulcerating growth." The unusual frequency with which patients with penile cancer have had venereal disease has been demonstrated by Dean (1935) and by Schrek and Lenowitz (1947), these authors having come to the conclusion that this fact indicates again the significantly low standard of social hygiene of these patients. A further factor frequently present in patients with penile cancer is phimosis; although this is often the result of the growth, in many patients the prepuce has never been retractable (Lewis, 1931).

With these facts it may reasonably be contended that, if the uncircumcised male has a prepuce which he can retract and which he keeps clean, he is likely to enjoy the same immunity from penile cancer as his circumcised brother.

Cervical Cancer in Women

The low incidence of cervical cancer among Jewesses has led Handley (1947) to the conclusion that this disease is mainly caused by the introduction of irritant material by the uncircumcised husband during coitus. It should be a simple matter to put this theory to the test by noting whether the husbands of women with cervical cancer are more frequently uncircumcised than others. Meanwhile the evidence seems insufficient to warrant universal circumcision or preputiotomy, such as Handley advocates.

Minor Advantages of Circumcision

There remain a number of more or less trivial factors which are sometimes mentioned as reasons why infant circumcision is desirable: difficulties in keeping the uncircumcised parts clean, or the supposed aesthetic or erotic superiority of the shorn member. In order to fulfil the intention of this paper an inquiry on these points should have been made amongst a group of uncircumcised men. This was not attempted, although with regard to the last two of the factors mentioned it should be stated that whenever the subject has been broached in male company those still in possession of their foreskin have been forward in their insistence that any differences which may exist in such matters operate emphatically to their own advantage.

Moreover, if there were sensible disadvantages in being uncircumcised, one would expect that the fathers of candidates for circumcision would sometimes register their feelings in the matter. Yet in interviewing the parents of several hundred infants referred for circumcision I have met but one father who wished his son circumcised because of his own disagreeable experience of the uncircumcised state. The rest of the fathers were equally indifferent about the matter whether they themselves had been circumcised or not. Indeed, so little did the father's personal experience seem important that one-quarter of the mothers did not even know whether their husbands were or were not circumcised. These facts provide

some evidence that few uncircumcised men have cause to regret their state.

Conclusions

It has been shown that, since during the first few years of life the prepuce is still in process of developing, it is impossible at this period to determine in which infants the prepuce will attain normal retractability. In fact, only about 10% will fail to attain this by the age of 3 years. Of this 10% of 3-year-old boys, in most it will be found a simple matter to render the prepuce retractable by completing its separation from the glans by gentle manipulation. In a very few this may prove impossible and circumcision might then be considered a justifiable precaution. Higgins (1949), with long experience of paediatric urology, also concludes that circumcision should not be considered until "after the age of, say, 2 to 3 years."

The prepuce of the young infant should therefore be left in its natural state. As soon as it becomes retractable, which will generally occur some time between 9 months and 3 years, its toilet should be included in the routine of bath time, and soap and water applied to it in the same fashion as to other structures, such as the ears, which are customarily treated with special assiduousness on account of their propensity to retain dirt. As the boy grows up he should be taught to keep his prepuce clean himself, just as he is taught to wash his ears. If such a procedure became customary the circumcision of children would become an uncommon operation. This would result in the saving of about 16 children's lives lost from circumcision each year in this country, besides saving much parental anxiety and an appreciable amount of the time of doctors and nurses.

Summary

The development of the prepuce is incomplete in the newborn male child, and separation from the glans, rendering it retractable, does not usually occur until some time between 9 months and 3 years. True phimosis is extremely rare in infancy.

During the first year or two of life, when the infant is incontinent, the prepuce fulfils an essential function in protecting the glans. Its removal predisposes to meatal ulceration.

The many and varied reasons commonly advanced for circumcising infants are critically examined. None are convincing.

Though early circumcision will prevent penile cancer, there is reason to suppose that keeping the prepuce clean would have a like effect in preventing this disease.

In the light of these facts a conservative attitude towards the prepuce is proposed, and a routine for its hygiene is suggested. If adopted this would eliminate the vast majority of the tens of thousands of circumcision operations performed annually in this country, along with their yearly toll of some 16 child deaths.

My thanks are due to Dr. A. M. Barrett for pathological facilities.

THE USE OF RADIOGRAPHS IN ASSESSING DISPROPORTION*

BY

J. CHASSAR MOIR, M.A., M.D., F.R.C.S.Ed. F.R.C.O.G.

Nuffield Professor of Obstetrics and Gynaecology, University of Oxford

What has radiology done to help the obstetrician with his problem-cases of disproportion? I do not doubt that some at this moment are muttering, "Nothing"; and perhaps a cynic is adding in ruder tones, "Less than nothing—it is a menace!" But I am equally sure that there are many others of a more sanguine disposition who take an opposite view; and one and all of us are, I hope, ready and willing to enter into a fair discussion concerning the merits of this new tool that has been put into our hands.

Why should there be any sharp difference of opinion; and why should there be, in some quarters, a distrust of radiography? Chiefly, I believe, it is because radiologists as a class have little first-hand knowledge of obstetrics and often fail to appreciate the intricacies of childbirth. Similarly, the obstetrician seldom has an understanding of the technical difficulties encountered in the *x*-ray room and often demands the impossible from the radiologist. Too often, therefore, an early enthusiasm gives place to a distrust or even frank disbelief regarding the value of radiology in assessing obstetrical disproportion. I must therefore first plead for the most intimate and genuine co-operation between obstetrician and radiologist if progress in this field is to be made.

No discussion on the topic of disproportion can escape the criticism that it deals with one aspect only of dystocia and ignores other factors of capital importance. No notice is taken, for example, of the force and frequency of the uterine contractions, of the adaptation and realignment of the soft tissues—particularly those of the lower uterine segment—of the mouldability of the baby's head, or of the "give" of the pelvic joints. Least of all does radiology measure the patient's psychology or fortitude, nor, as I jocularly add to my students, does it judge the character, size, and proximity of the mother-in-law! Yet of all the causes of dystocia, disproportion is the most important; and it is therefore right that it should be singled out for special consideration.

Development of Radiographic Pelvimetry and Cephalometry

Looking back over the development of obstetric science, we see an early recognition of the importance of pelvic measurement. William Smellie knew full well the meaning of the flattened pelvic brim and the ominous significance of a projecting sacral promontory. Baudelocque, Michaelis, and others developed this science; and by the end of the nineteenth century pelvimetry was recognized as an essential part of every obstetrical examination.

Now comes the paradox. In modern times a new method of obtaining this supposedly vital information—and of obtaining it with undreamed-of accuracy—has been placed in our hands. Yet contemporaneously with this wonderful development there has arisen a generation of obstetricians who maintain that exact pelvic measurement is, generally speaking, unnecessary and even misleading and declare that the many components collectively making for eutocia

*Paper read at the combined meeting of the Sections of Obstetrics and Gynaecology and Radiology at the Annual Meeting of the British Medical Association, Harrogate, 1949.

on the one hand or dystocia on the other are so complex and varied as to render useless any system of prognosis that is based on one factor or even one set of factors. While I acknowledge the complexity of the subject I do not share these extreme opinions, which seem a counsel of despair, and which, I suspect, are sometimes voiced with insufficient knowledge of the position now reached in obstetric science. And among the iconoclasts one can sometimes perceive an inconsistency, for in those very centres where radiology is viewed with distrust or even antagonism there are in use antenatal charts in which space is provided for pelvic measurements obtained by clinical means. To quote my own words used on a previous occasion, "Disproportion in its widest sense is chief among the causes of difficult childbirth, and here it is that radiology gives most help. If we trouble to take pelvic measurements at all we show our belief in their value, and, if we so believe, then surely it is right to strive for fuller knowledge and greater accuracy."

Possibly some of the opposition to radiography has come from the fact that methods of pelvimetry have been, in some cases, only doubtfully accurate. Here it may be useful to point out that an error in positioning the patient during radiological examination inevitably results in the pelvic size appearing *smaller* than it really is, while in like circumstances the foetal head appears *larger* than it really is. In consequence an entirely erroneous appearance of disproportion may easily be presented, and a forecast made that is belied by subsequent events. But still more important in this connexion is the surprisingly tardy appreciation of the fact that adequate pelvic measurement requires far more than a mere recording of the conjugata vera—important as that time-honoured measurement is. A small brim conjugate may mean little if the pelvis is generous in other dimensions; and, conversely, a generous brim conjugate is no talisman against dystocia if serious diminution of capacity is present in other respects. It follows that, to be efficient, radiological examination must include examination of the pelvis in more than one projection.

Pelvic Shape

And now a word about pelvic shape as distinct from details of pelvic size. There is nothing new in saying that the "mechanics" of labour are largely governed by pelvic shape. But this truism took on a new meaning when Caldwell and Moloy by their admirable work with the radiographic stereoscope distinguished in more precise fashion certain trends that occur in pelvic architecture, and linked those trends with peculiarities in the manner of descent of the head. For example, they (and Herbert Thoms before them) associated the occipito-posterior descent of the head and face to pubes delivery with a pelvis in which the antero-posterior diameter was equal to, or exceeded, the transverse. But space does not allow me to elaborate this topic. This only I would say in passing: any system of pelvimetry must make allowance for the influence of pelvic shape as well as pelvic size if it is to form a basis for obstetrical prognosis.

Radiographic Technique

I shall not here discuss radiological technique. A bewildering variety of methods of pelvimetry and cephalometry have been devised; and, so long as the method is reliable, its choice must be left to the discretion of the radiologist. In passing I may remark that there seems to be an irresistible fascination for the mechanically minded enthusiast to introduce new methods, or new modifications of standard methods. And here I accuse myself, for if this is a sin I have a burden to bear. But such modifications as I have favoured have been directed to simplifying matters at the time of the examination, and I therefore deem my burden light.

Assessing Disproportion

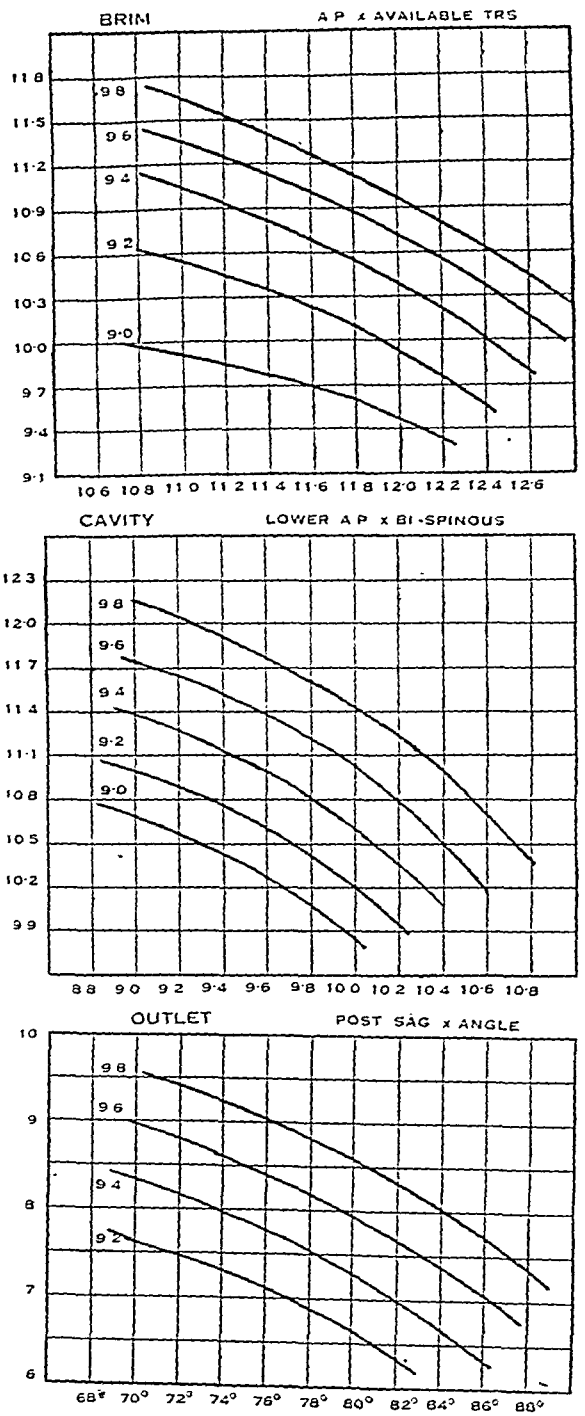
I now come to the main topic—the methods of assessing disproportion. Let us start with the simplest of all: the radiologist views the radiograph and allows the general impression thus received to prompt him to an opinion regarding prognosis. This method—for lack of a better title let it be called the impressionistic method—has been developed to its fullest extent by Caldwell and Moloy and their followers (Caldwell, Moloy, and Swenson, 1939): and here I include Miss Meave Kenny, who has done excellent work on this line at the British Postgraduate Medical School (Kenny, 1944). By use of the Moloy stereoscope the relation of the foetal head to the maternal pelvis can be surveyed in three dimensions. Now, there is obviously much to be said in favour of this method, which, incidentally, enabled Caldwell and Moloy to break new ground and to study the influence of pelvic shape on the course of labour, to which reference has been made. I myself gladly acknowledge personal help from these workers and have made considerable use of their method. Nevertheless, it has disadvantages. It is exacting and time-consuming; moreover, not every observer has adequate stereoscopic vision. At the best the method is essentially impressionistic. Judgment is given on features rather than accurately measured or recordable findings; and obviously there is no certainty that different observers will agree on individual cases.

In 1935 Ball and Marchbanks, of New York, reported a method of estimating head volume and comparing it with pelvic capacity. Theoretically, it is probably the best of all methods, but the technical difficulties are formidable and few workers appear to have followed this line.

In this country, Nicholson, of Moreton-in-Marsh (Nicholson, 1938, 1943), developed a method of pelvimetry based on an original and ingenious method of utilizing parallax-shift measurements. He then evolved a method of measuring the available area at different pelvic levels, and from observations compiled in his own practice was able to assess the significance of various types and degrees of pelvic contraction. For example, a brim reduced to 90 sq. cm. was an indication, he believed, that a "level of uncertainty" had been reached. I much admire Nicholson's work, which, I would remind my listeners, was done as a side interest in a busy general practice. It has done good by focusing attention on the need for accurate measurement and providing, for the benefit of other workers, possible formulae by which the obstetrical value of the pelvis may be judged. Curiously, however, Nicholson has paid little heed to the size of the foetal head—a matter which, in my opinion, is almost as important as the computing of pelvic measurements; nor is it clear that he has sufficiently considered the variation of prognosis that derives from variation in pelvic shape.

In 1933 Thoms, of New Haven, described the construction of pelvic or, as I shall call them to avoid confusion, anatomical charts in which the outline of the pelvis was reduced to its true size and shape. This he did for both the brim outline (supero-inferior projection) and for the pelvic canal outline as seen in lateral profile. Some 12 years ago I was fortunate in being able to see Thoms's work at first hand, and was much impressed by its value. Soon afterwards I tried to add to the usefulness of Thoms's charts by superimposing on them an ellipse which

represented, as nearly as possible, the area that would be occupied by the particular foetal head that was to descend through that pelvis (Moir, 1941). This was done with regard to the pelvic brim and also the pelvis at the level of the ischial spines. A visual impression was thus conveyed of the difficulties (if any) that would be encountered during the descent of the head. This, I felt, was a welcome improvement on purely impressionistic methods of assessing disproportion.



Rohan Williams (1943 ; Williams and Phillips, 1946) has contributed notably in this field by developing the anatomical chart method in new ways, particularly with regard to the lateral profile charts. In place of a static ellipse drawn on the charts he employs a circular disk (or set of variously sized disks) which he passes back and forwards over the chart to help him to form an opinion regarding the space available for the head at the various levels. This method has given excellent results in his hands, and in a series of cases of clinically suspect abnormality he has been able to show a correct forecast of labour in 83%, and a "substantially correct" forecast in 90%, of assessable cases. (The second group includes those in which the forceps operation was used, but without signs of cephalo-pelvic disproportion during labour.)

I cannot here do more than mention the names of Peter Allen, of New Zealand, and Morris, of Edinburgh, both of whom have made valuable contributions to this subject and clarified certain obscure features regarding pelvic measurement.

To return now to my own work, this branched off on lines somewhat different from those just described. I early realized that the construction of the anatomical charts was a time-consuming occupation and that, when all was said and done, they resulted only in providing a visual impression of certain features which could also be expressed in simple figures. I therefore evolved a method which, it seemed, would still give a desirable visual impression but which would be quicker and easier to operate. Details have been published elsewhere (Moir, 1946, 1947, 1949). Briefly, three standard charts on graph paper were constructed—one for the pelvic brim, one for the pelvis at the level of the ischial spines, and one for the outlet. Each chart had the antero-posterior measurements indicated along its vertical edge and the transverse measurements along its horizontal edge. It was thus an easy matter to pin-point at will the main size and shape characteristics of any pelvis. Now, by reviewing and correlating a large number of previously observed obstetrical cases in which full radiological examination had been made, it was possible to indicate on each chart the level at which difficulty was encountered with reference to the degree of head size. The end result was the incorporation in the charts of a series of lines or graphs by which one could tell in any particular case whether head size would encroach to a significant degree on pelvic size, or, to use more familiar words, whether dystocia from cephalo-pelvic disproportion was likely (Fig. 1).

These charts have now been in use for nearly five years and I have found them of very real help in summing up the mechanical features of an obstetrical case. They can be prepared without any great expenditure of time or effort, and can be included in antenatal records and accompany the patient to the labour room.

Critics sometimes ask whether this use of radiography has increased the incidence of caesarean section. To this I can reply that radiographic study of the pelvis has oftener influenced me against that operation. For example, on many occasions when pelvic contraction—even contraction of considerable degree—has been diagnosed by clinical

Charts Used in Cases of Suspected Cephalo-pelvic Disproportion (Measurements in Centimetres).—The chief pelvic measurements can be indicated by a "cross" made on each chart. If the cross lies above and to the right of the line representing the estimate of biparietal head size, mechanical difficulty is highly improbable; if it lies below and to the left, mechanical difficulty becomes probable and increases with the distance from the critical level. Forecast of difficulty is very accurate with regard to the brim chart. It is less accurate if based exclusively on findings in the cavity or outlet charts, for the reason that the lower pelvis may in some cases expand during labour.

means, the radiographic examination has shown that the foetal head was also small, and that while there was undoubted pelvic contraction there was no true disproportion. Indeed, it is quite surprising how often this is so: the small woman very often has the small baby. Occasionally, however, the charts reveal grave difficulty of which no adequate warning is given by clinical examination. In these cases I have hitherto usually adopted the policy of allowing a "trial of labour," for I have realized that the radiographic method has still to prove its worth. But this I can say with full assurance: the charts quickly "separate the sheep from the goats" (I trust this expression will not cause offence!), and show at once which patients are suitable for domiciliary delivery and which should be referred to hospital for careful supervision.

It is difficult to give statistics regarding the accuracy of the obstetric forecast, for there is, in practice, no uniformly applicable yardstick by which this can be judged. How is one to define, for example, what is meant by a difficult labour and what is meant by an easy labour? How is one to class the case in which there has been a long and obviously difficult labour but no evidence of cephalo-pelvic disproportion—for example, the primigravida with primary inertia followed, maybe, by a contraction ring? Again, what is one to say about the case in which an over-enthusiastic house-surgeon has applied forceps for indications that would generally be deemed inadequate? These and other difficulties in assessing results become obvious when statistics are being compiled; and no system of prognosis, however good in itself, can therefore give a forecast that approaches 100% accuracy. Nevertheless, having regard to these limitations, a strict analysis of 193 assessable cases of clinically suspect pelvic abnormality was attempted and gave the following results.

When easy delivery was indicated by the graphs the labour in 72% of cases was found to be short, spontaneous, and uneventful. This figure would be higher if borderline cases were included or allowance made for the "substantially correct" diagnosis as defined by Rohan Williams.

When difficult delivery was indicated by the graphs the labour in 86% of cases was found to be prolonged or to require operative assistance. When dystocia was indicated by contraction in the brim graph, as distinct from the cavity and outlet graphs, the accuracy was even higher.

These results were on an early series; with further experience a higher rate of correct forecast seems possible, and this, I hope, will be the subject of a future report.

Intra-partum Radiography

And now a brief note on intra-partum radiography. It is quite remarkable how little attention has hitherto been paid to this obvious use of the radiograph. By it the progress of labour can be observed, and much help given, for example, in the conduct of the "trial-labour" case. It will show whether the greatest diameter of the head has passed or has nearly passed through the narrowest part of the pelvis, and hence whether or not it is reasonable to subject the mother and the baby to further hours of "trial labour." One can only suppose that lack of radiographic facilities has been the reason for this failure to utilize a modern diagnostic method, and it seems to me that an obstetric hospital without radiographic facilities for the parturient woman is as much an anachronism as, say, a cardiological hospital without an electrocardiograph.

Conclusion

Finally, a word of warning. Let no one suppose that radiography provides a short cut to good obstetrics. The clinical problems involved are sufficiently numerous and varied to make any such supposition quite untenable. But, on the other hand, he is a bold man who would brush aside the help that radiography can give. To ignore its aid and to trust exclusively to clinical judgment in sizing up the problems presented in a border-line case of disproportion is, to my mind, a policy reminiscent of the alleged behaviour of the ostrich on the approach of danger.

GROWTH OF THE FOETAL BIPARIETAL DIAMETER DURING THE LAST FOUR WEEKS OF PREGNANCY*

BY

SYDNEY JOSEPHS, M.D., D.M.R.

Assistant Radiologist, Newcastle General Hospital, Newcastle-upon-Tyne

With Statistics by H. Campbell, B.A., F.S.S.

Nuffield Department of Industrial Health, University of Durham King's College, Newcastle-upon-Tyne

It has long been accepted that the foetal skull grows at a uniform rate during the last weeks of pregnancy, and this view is supported by the work of Scammon and Calkins (1929). They state that the foetal biparietal diameter increases by approximately 0.1 in. (2.5 mm.) a week during the last four weeks of pregnancy, and Reece (1935) based his method of estimating the age of the foetus on their growth curve of the biparietal diameter.

Three years ago the departments of radiology and obstetrics at the Newcastle General Hospital decided to try out a new method of cephalometry. In an attempt to check its accuracy by direct measurement of the foetal head after delivery the following course was adopted.

After each cephalo-pelvic estimate a copy of the radiologist's report, with the date of examination, was filed in a card index. A list of all patients examined, containing no other information than the expected dates of delivery, was kept by Dr. Ruth Fawcett, paediatric registrar to the maternity department, who then measured the biparietal diameter of each baby's head on the third day after delivery. This day was chosen because by that time it was considered that the effects of moulding would have disappeared (Chassar Moir, 1946). The measuring was done with a pair of engineer's callipers, and it was Dr. Fawcett's practice to measure each biparietal diameter three times, the mean of these three measurements being

*Read at a combined meeting of the Sections of Obstetrics and Gynaecology and Radiology at the Annual Meeting of the British Medical Association, Harrogate, 1949. The paper was based on a thesis presented for a degree of M.D. at the University of Durham, June, 1949, with the addition of fresh cases and material.

FIG. 1.—Radiograph taken on February 11.

FIG. 3.—The foetal skull shadows in Figs. 1 and 2 are shown superimposed.

FIG. 2.—Radiograph taken on March 4.

FIG. 4.—The maternal pelves are shown superimposed. The descent made by foetal head in 21 days is seen.

taken as the observed biparietal diameter of the baby's head. These were true independent observations, unbiased by any knowledge of the radiological estimations.

The biparietal diameter was chosen for the following reasons: (1) It, or its equivalent diameter of the greatest circular section of the foetal head, is recognizable in any projection of the foetal skull (Reece, 1935). (2) It is the most certainly defined diameter when measuring the baby's head after birth. (3) In the majority of cephalic

presentations the biparietal diameter of the foetal head engages with the antero-posterior diameter of the pelvic brim, which is usually the shortest diameter of the inlet.

Results

In 189 cases the biparietal diameters were estimated radiologically *in utero* and subsequently measured with callipers after birth; of these, 34 were examined twice, giving 223 radiological examinations.

Eighty-four cases were examined radiologically seven days or less before delivery, 13 of them actually on the day of delivery, so that the growth that could have occurred between the radiological and calliper measurements was negligible. These 84 cases were used, therefore, to check the accuracy of the method. The two sets of measurements are shown in Table I.

TABLE I.—*Biparietal Diameter of Foetal Skulls*

	Radiological Measurement	Calliper Measurement
No. of cases	84	84
Mean biparietal diameter	3·700 in. (9·4 cm.)	3·680 in. (9·35 cm.)
Standard deviation	0·138 in. (3·505 mm.)	0·124 in. (3·15 mm.)
Standard error of mean	0·015 in. (0·38 mm.)	0·014 in. (0·355 mm.)

It is therefore apparent that the radiological method gives an accurate estimate of the post-natal measurement, with a slight tendency to exaggerate it by 0.02 in. (0.5 mm.). In individual cases, however, there are certain discrepancies which require further consideration. The difference between the intrauterine measurement and the post-natal measurement for these 84 cases is shown in Table II. A negative discrepancy indicates that the intrauterine measurement was larger than the post-natal one.

TABLE II.—*Discrepancies in the Radiological Estimation of the Biparietal Diameter of the Foetal Skull*

Discrepancy in Inches	No. of Cases	Discrepancy in Inches	No. of Cases
−0·20 (−5·08 mm.)	1	+0·05 (+1·27 mm.)	12
−0·15 (−3·81 mm.)	7	+0·10 (+2·54 mm.)	10
−0·10 (−2·54 mm.)	20	+0·15 (+3·81 mm.)	3
−0·05 (−1·27 mm.)	13	+0·20 (+5·08 mm.)	1
0·00	17		

Mean discrepancy = −0·020 in. (−0·508 mm.)
Standard deviation = 0·087 in. (2·210 mm.)
Standard error = 0·010 in. (0·254 mm.)

From this table it is apparent that no error occurred greater than 0.2 in., and on the basis of these figures the following limits of accuracy for individual cases may be claimed: (1) 75% of all cases will be predicted within 0.1 in.; and (2) 95% of all cases will be predicted within 0.15 in. (3.8 mm.) of the calliper measurements. For groups of over 16 cases, however, accuracy to within 0.02 in. may be claimed for the mean reading.

It was observed during this investigation that, although the majority of biparietal estimations carried out during the last seven days of pregnancy were accurate to within 0.1 in., the calculated biparietals were always too large when cephalometry was performed earlier than two weeks before delivery. They were too large in every case, provided an allowance was made for growth of the biparietal diameter at a rate of 0.1 in. a week.

For example, if a biparietal diameter was estimated at 3.6 in. (9.14 cm.) at the 37th week of pregnancy, 0.3 in. (7.6 mm.) was added for growth (Scammon and Calkins, 1929) and the calliper measurement should have been 3.9 in. (9.9 cm.). In fact, however, the calliper measurement was found to be 3.6 in., and this disparity was true of every case examined during the 36th to 39th weeks of pregnancy.

There were therefore two possibilities to be considered either (*a*) our method of cephalometry was accurate during the last week of pregnancy, but inaccurate if performed earlier than two weeks before delivery, or (*b*) the foetal biparietal diameter did not grow during the last four weeks of intrauterine life. The latter concept was supported by the fact that the biparietal diameters estimated during the last four weeks were the same as the observed measurements carried out after delivery. We tried, therefore, to obtain further evidence to support this premise.

A group of cases were sent for cephalometry at the clinically estimated 36th week of pregnancy, and cephalometry was repeated four weeks later. The case sheets of this group were marked so that if the patient came into labour before the expected date emergency cephalometry could be performed.

The following is an example of one of these cases.

A primigravida aged 27 was sent for pelvi-cephalometry on February 11, 1949, and the foetal biparietal diameter was calculated to be 3.55 in. (9.02 cm.) on that date (Fig. 1). Twenty-one days later, on March 4, cephalometry was repeated, and the foetal biparietal diameter was calculated to be 3.6 in. (Fig. 2) —an increase of 0.05 in. (1.27 mm.), which is within the limits of experimental error. Eight days after this, on March 12, a female infant weighing 7 lb. 9 oz. (3.43 kg.) was delivered normally, and its biparietal diameter measured 3.55 in. There was thus no increase in the foetal biparietal diameter during the last 29 days of this pregnancy.

Fig. 3 shows the two previous films arranged so that the foetal skull shadows are superimposed, and it can be seen that they do accurately coincide. Fig. 4 shows the two maternal pelves superimposed, showing that the foetal head has made some descent during the 21 days between exposures.

In each of the 223 radiological estimations the amount of growth from the date of the examination until the date

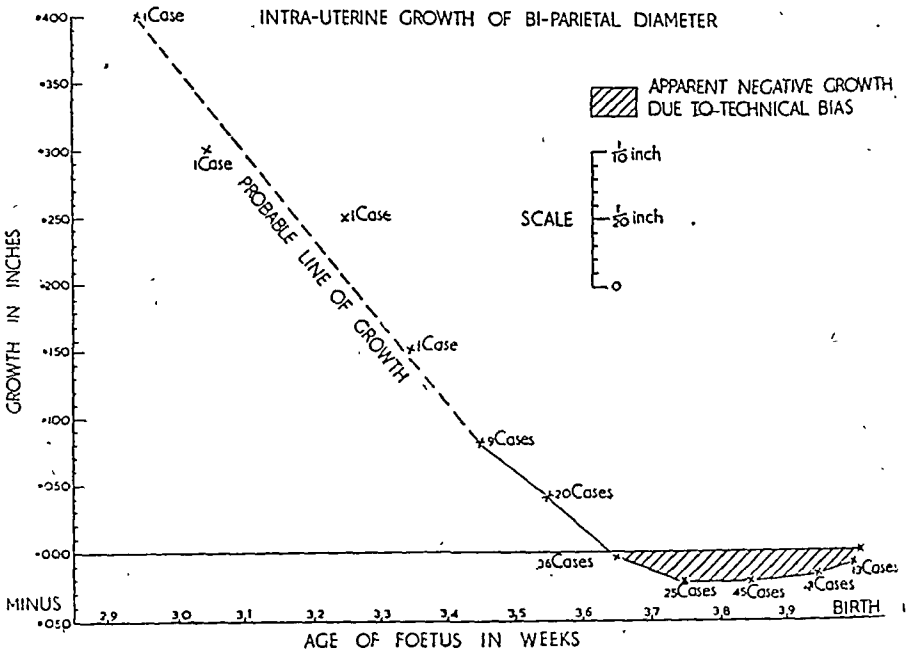

FIG. 5.—The total growth of the biparietal diameter of the foetal skull from the date of estimation until birth. The growth of the skull is estimated from the intrauterine radiological measurement and the actual calliper measurement three days after birth; the difference between these readings gives the growth in the intervening period.

of delivery was calculated from the two readings available. The cases were then grouped according to the number of weeks that elapsed between examination and delivery, and an average of each group was calculated. These growth figures are given in Table III. The standard error of the means of these groups is ±0.02 in.

TABLE III.—*Average Growth of Biparietal Diameter from Date of Examination to Date of Delivery*

Week of Pregnancy	Days Before Delivery	No. of Cases	Average Growth
40	Same day	13	−0·008 in. (−0·203 mm.)
39	1–7	71	−0·022 in. (−0·559 mm.)
38	8–14	45	−0·024 in. (−0·609 mm.)
37	15–21	25	−0·024 in. (−0·609 mm.)
36	22–28	36	−0·005 in. (−0·127 mm.)
35	29–35	20	+0·042 in. (+0·067 mm.)
34	36–42	9	+0·078 in. (+1·981 mm.)
33	43–49	1	+0·150 in. (+3·810 mm.)
32	50–56	1	+0·250 in. (+6·350 mm.)
31	—	—	—
30	64–70	1	+0·300 in. (+7·620 mm.)
29	71–77	1	+0·400 in. (+10·160 mm.)

The notable features of this table are: (1) The radiological method overestimates the size of the head by approximately 0.02 in. Consequently there is an apparent slight negative growth in the later stages (see Fig. 5). (2) There is no sign of a growth curve between the 36th and 40th weeks of pregnancy. (3) The growth curve between the 30th and 36th weeks cannot yet be accurately assessed, owing to scanty data, but even at this stage the biparietal diameter appears to grow at a rate of less than 0.1 in. a week.

We have now collected 34 cases in which radiological cephalometry was performed twice, with an interval of 21 days or more between the examinations. In 13 cases both radiological examinations were performed during the last 28 days of pregnancy, and the apparent growth between the two radiological examinations was 0.02 in. This figure is within the limits of our experimental error and could not therefore be definitely attributed to growth. Further details of these 34 cases are given in Table IV.

TABLE IV.—*Results of Two Radiological Examinations in Same Patient*

Time from First Radiological Examination to Date of Delivery	No. of Cases	Average Time between Two Radiological Examinations	Average Growth between Two Radiological Examinations
28 days or less	13	24 days	0·02 in. (0·508 mm.)
29–35 days	13	26 ,,	0·04 in. (1·016 mm.)
36 days or more	8	30 ,,	0·12 in. (3·048 mm.)

For reasons stated above we have estimated radiologically only the biparietal diameters, and have no observations to offer on the growth, or lack of growth, of the other diameters of the foetal skull during this period. In the absence of craniostenosis, however, it seems illogical to suppose that one diameter of the foetal skull should remain stationary while the others increase.

The investigation continues, and we are trying to estimate the foetal biparietal diameters at 32 weeks, again at 36 weeks, and then at term. Thereby we hope to observe the rate of growth between the 32nd and 36th weeks of pregnancy and to obtain further confirmation of the absence of growth between the 36th and 40th weeks.

Summary

Two hundred and twenty-three estimations of intrauterine foetal biparietal diameters, performed on 189 patients, are compared with calliper measurements obtained on the third day after birth.

Eighty-four cases were estimated radiologically within seven days of delivery.

In 34 cases radiological cephalometry was performed twice, with a minimum of 21 days between the examinations.

For individual cases the predicted measurement will be within 0.1 in. of the calliper measurement in 75% of cases, and within 0.15 in. in 95% of cases.

For groups of over 16 cases, accuracy of 0.02 in. may be claimed for the mean reading.

Radiological cephalometry overestimates the biparietal diameters by approximately 0.02 in.

There is no sign of a growth curve between the 36th and 40th weeks of pregnancy.

Grateful thanks are due to the staffs of the obstetrical and radiological departments of the Newcastle General Hospital; to Mr. F. Pearse, senior radiographer, who produced many of the radiographs of these cases; to Dr. Mary Buchanan and Dr. W. Ingham, who assisted Dr. Fawcett in her measurements; to Dr. Whately Davidson, radiologist in charge, Newcastle General Hospital, Mr. Linton Snaith, obstetrician in charge, Newcastle General Hospital, and Dr. Blair Hartley, honorary radiologist to the Christie Hospital and Holt Radium Institute, Manchester, for their criticism and encouragement in this work.

THE SHORT OESOPHAGUS

A REVIEW OF 31 CASES

BY

J. BASIL RENNIE, M.D., M.R.C.P., F.R.F.P.S.G.

S. D. SCOTT PARK, M.B., Ch.B., D.M.R.E.

(From the Gardiner Institute of Medicine, University of Glasgow, and the Ear, Nose, and Throat and Radiology Departments, Western Infirmary, Glasgow)

Although the association of gastric hernia with shortening of the oesophagus is no new conception, it is far from widely appreciated that it can produce a variety of symptoms simulating carcinoma of the oesophagus, peptic ulceration of stomach or duodenum, cholelithiasis, and even disease of the coronary arteries. In this communication, therefore, we propose to review the literature briefly, to discuss the incidence of the condition relative to other lesions of the lower third of the oesophagus, and to point out associations with pregnancy and post-operative oesophageal stricture which we believe have not been previously recognized.

Isolated references to patients described as having a short oesophagus were recorded years ago by physicians from findings at necropsy (Bright, 1836; Bund. 1918; Bailey, 1919). The radiologist Akerlund (1926) seems to have been the first to differentiate hernia of the stomach through the oesophageal hiatus into three types according to the *x*-ray appearances (Fig. 1). In the oesophago-gastric variety (*a*) the oesophagus is redundant and tortuous, in the para-oesophageal (*b*) the oesophagus enters the stomach below the diaphragm and the gastric hernia passes up beside it, while in hiatal hernia with short oesophagus (*c*) the gastro-oesophageal junction is above the diaphragm but the oesophagus is not redundant.

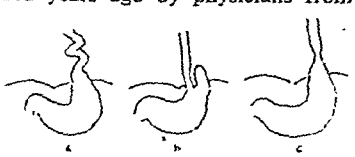

FIG. 1.—Varieties of gastric hernia through the oesophageal hiatus. *a*, Oesophago-gastric; *b*, para-oesophageal; *c*, with short oesophagus.

The first clinical records of a series of cases were published by Findlay and Brown Kelly (1931). Their nine patients were young children in whom regurgitation developed shortly after birth or when solid food was first taken. With barium swallowed in the horizontal position, oesophageal stenosis was found well above the diaphragm, and below it a pouch in which rugae were seen passing through the oesophageal hiatus and continuous with those of the stomach. Confirmation that this pouch was in fact part of the stomach was obtained from oesophagoscopy and biopsy. In the opinion of Findlay and Brown Kelly, this shortening of the oesophagus was congenital, although later Brown Kelly (1936) appears to have thought that in some instances the shortening was cicatricial and secondary to oesophagitis.

Shortly after the paper by Findlay and Brown Kelly, Monkhouse and Montgomery (1933) reported seven instances in adults. In the same year peptic ulceration in the lower end of the short oesophagus was conclusively demonstrated by Clerf and Manges (1934). They described 14 patients, children as well as adults, who had a short oesophagus and thoracic stomach, an ulcer being found in four. Biopsy in eight cases showed gastric mucosa above the level of the diaphragm. The presenting symptom in those with ulcer was burning pain at the lower end of the sternum, coming on immediately after taking solid food, and tending to radiate through to the back between the shoulder-blades or up to the root of the neck and sometimes down the left arm. It was relieved by alkalis, by regurgitation, or by drinking bland fluids, and was made worse by lying down. Dysphagia often did not appear until pain had been present for months or years. In those in whom no ulcer was demonstrated dysphagia was the presenting symptom, and in one patient in whom complete oesophageal obstruction was precipitated by impaction of a piece of apple it had been present from birth.

Clerf and Manges emphasized the importance of the observation made originally by Soresi (1919) in regard to diaphragmatic hernia in general, that to demonstrate part of the stomach above the diaphragm it was essential to lower the head of the table to allow the barium to flow back through the cardia. They found that the best view was obtained with the patient semi-supine in the right oblique position. Failure to use this technique meant failure to reach a correct diagnosis, as only the oesophageal stenosis was revealed by barium swallowed in the upright position, while the thoracic stomach, essential for the diagnosis, was missed. They also held that the lesion was a congenital shortness of the oesophagus accompanied by thoracic stomach—i.e., the cardiac part of the stomach had never descended below the diaphragm in course of development. A predisposition to peptic ulceration of the oesophagus existed because of reflux of gastric juice through the cardia, which was incompetent in its thoracic position. Increase or onset of pain on lying down was held to support this hypothesis.

The occurrence of short oesophagus with thoracic stomach and its association with oesophageal ulcer has been noted by many other observers (Dunhill, 1935, 1937; Chamberlin, 1938; Feldman, 1939; Cleaver, 1943). Among the later workers, Johnstone (1941) recorded seven examples in all of which a chronic peptic ulcer of the oesophagus was present. He held that shortening of the oesophagus occurred as a sequel to the ulceration and that the cardia was as a result drawn above the diaphragm. In support of this view he pointed out that all his cases were at or above middle age. On the other hand Dick and Hurst (1942) believed that a chronic ulcer of the oesophagus seldom occurred save as a sequel to congenital shortening of the oesophagus and thoracic stomach. In the few cases in which this abnormality was not demonstrated the ulcer was ascribed to the secretion of gastric juice by heterotopic gastric mucosa in the oesophageal wall. They considered that the symptoms of which a patient with a short oesophagus complained were as a rule those due to the ulcer, and if there were no ulcer the condition was latent and was found fortuitously on barium examination. It was also noted that pain was made worse not only on lying down but on bending, whereby intra-abdominal pressure was increased and gastric juice regurgitated into the oesophagus.

Polley (1941) had noted that in some cases pain had radiated into the neck and down the left arm. As a rule dysphagia occurred only after days or even weeks of pain. Intermission of symptoms was often observed, suggesting that spasm from the ulcer was the initial cause of dysphagia, while organic stricture gave rise to permanent dysphagia and required dilatation for its relief. In a recent review of the subject Allison (1948) discussed 78 examples of oesophageal ulcer or stricture all but two of which were associated with hiatal hernia and short oesophagus.

From the point of view of the radiologist the literature has been well reviewed by Smithers (1945).

In the present paper are described the clinical features of 31 patients with hiatal hernia and short oesophagus who were admitted to the Western Infirmary, Glasgow, over a period of 10 years.

Incidence

The frequency of short oesophagus relative to other common lesions in the lower third of the oesophagus is shown in Table I. Thus of 139 patients seen during a period of 10 years complaining of dysphagia due to obstruction in that site, 80 had carcinoma; achalasia was the cause in 31, and short oesophagus with benign stricture or active oesophageal ulcer in 26. Excluding the two cases due to swallowing of caustic, benign stricture was not seen in the lower third except in association with short oesophagus.

TABLE I.—*Frequency of Lesions of the Lower Third of the Oesophagus with Dysphagia (1937–46)*

Carcinoma	80 (all sites 203)
Achalasia	31
Hiatal hernia with short oesophagus	26 (+5 without dysphagia)
Fibrous stricture (caustics)	2

Short oesophagus was discovered during the barium examination of five patients whose symptoms of haematemesis or severe flatulence were unrelated to the oesophagus. Since this survey was made largely in retrospect, it is probable that some cases were missed. An attempt was made to re-examine all those in whom there was doubt about the cause of dysphagia in the lower third of the oesophagus, but three patients could not be traced.

It is certain that small sliding gastric hernia with shortening of the oesophagus occurs without symptoms, as it can be demonstrated when the appropriate radiological technique is employed. Kemp Harper (1946) put the incidence at 2% of all patients undergoing routine barium-meal examination. One of us (S. D. S. P.) confirmed this observation in 100 consecutive barium investigations.

Symptomatology

The age-and-sex incidence is shown in Table II, and is contrasted with that of achalasia and carcinoma of the lower third of the oesophagus. The age is that at the onset of symptoms in each group.

TABLE II.—*Age and Sex of Patients with a Lesion in the Lower Third of the Oesophagus*

Age at Onset	Short Oesophagus		Achalasia		Carcinoma	
	M	F	M	F	M	F
0–19 years ..	2	2	1	1	0	0
20–39 ,, ..	2	6	2	11	1	0
40–59 ,, ..	5	8	9	5	23	11
60–80 ,, ..	1	5	1	1	38	7
	10	21	13	18	62	18

Earlier workers found that symptoms associated with short oesophagus might appear at any age. In our series three patients had dysphagia from childhood, but in the majority no complaint was made before middle or late adult life, the oldest being 74. Only one case of cancer of the lower third of the oesophagus was observed in a person under 40 years of age, in a man of 26.

The sex incidence of short oesophagus (Table II), found to be about equal by Dick and Hurst (1942) and by Allison (1948), showed a preponderance of females in the ratio of 2 to 1 in our series. In achalasia this difference was less marked, while in carcinoma the ratio of males to females was 3.4 to 1.

The presenting symptom was pain in three cases, dysphagia in eight, and pain and dysphagia together in 13. This does not accord with the observations of Dick and Hurst (1942), who found that often pain alone was present, sometimes for years, before the onset of dysphagia. Two patients, without previous complaint related to the alimentary system, were admitted to hospital because of massive haematemesis. Analysis of the symptoms in our cases agrees for the most part with the clear descriptions by Clerf and Manges (1934) and later by Dick and Hurst (1942). Pain was complained of by 18 patients. In 13 instances it was felt at the lower end of the sternum, three times high in the epigastrium, and once each in right and left hypochondriac regions. It tended to radiate upwards behind the sternum and through to the back. Two patients complained of radiation to the neck and down the outer aspect of the arm—the left in one, the right in the other. In character it was burning, often coming on immediately after swallowing solid food, particularly meat or fibrous vegetables. It lasted for several minutes and was relieved either when the food was felt " to pass on into the stomach " or was regurgitated. In others the onset of pain was delayed for about 30 minutes and was relieved by regurgitation or by taking bland fluid. Alkali was often helpful. In addition to pain associated with food eight patients experienced pain on lying down or on bending forward. Five said that posture had no influence.

Dysphagia and Regurgitation.—Difficulty in swallowing solid food was felt by 26 patients, and 21 regurgitated food in varying degree. Complete obstruction to the passage of food was precipitated in two patients with partial stricture —in one by impaction of a piece of wood in a sausage, in the other by a piece of orange and again, two years later, by a raisin.

Haematemesis.—This occurred in nine cases. In five instances it was slight and recurrent, and in some consisted of altered blood. The other four patients were admitted to hospital as cases of emergency because of gross vomiting of blood; in two of them bleeding occurred without warning or any symptom of alimentary disorder.

There was one example of chronic haemorrhage with anaemia in the series.

Case 1.—A woman aged 36 had for over a year felt dull pain in the epigastrium relieved by food. No regurgitation. Stools were occasionally dark. Breathlessness, fatigue, and pallor had been present for some months, due to anaemia. Hb, 47%; R.B.C., 3.7 millions; occult blood was present in the faeces. A radiograph showed a short oesophagus and thoracic stomach but no stricture. No ulcer was seen in the oesophagus, stomach, or duodenum.

In this group a definite ulcer was located twice—once in the thoracic pouch of stomach, and once in the lower oesophagus. In the others an associated acute peptic ulcer of stomach or duodenum may have been responsible, as these lesions may be undetectable by radiology within a few weeks of the bleeding. The other possibility is haemorrhage from erosions in the thoracic pouch which are prone to occur because of congestion of the mucosa in that site. In two of this group dysphagia did occur later.

Flatulence.—This was a prominent complaint in four patients. Dysphagia was absent in two and minimal in two.

Case 2.—A woman of 56 had for at least 15 years complained of pain under the left costal margin and very severe flatulence after meals. In 1934 cholecystectomy had been performed without relief, no stones having been found. Peptic ulcer and spastic colon were diagnosed on subsequent occasions, but no proof of either of these lesions was found. In 1942 the pain was gnawing in character and was relieved by vomiting and by alkaline powder. No complaint of dysphagia was made. On her last admission in 1942 a radiograph showed a short oesophagus and a thoracic stomach. No oesophageal stricture or ulcer was seen. This was an *x*-ray diagnosis and was reached quite by chance so far as the clinician was concerned.

Intermission of the Symptoms.—This was characteristic, 21 patients agreeing that the severity of pain and difficulty in swallowing varied. Some lost their pain after months or years but were left with dysphagia, because of which they had to eat only food which could be very thoroughly masticated.

X-ray and Oesophagoscopic Appearances

In the earlier part of the period covered by this survey the actual barium swallow was as a rule given to patients in the standing position only. A typical picture of the result thus obtained is given in Fig. 2, which shows a partial stricture with irregular wall some distance above the diaphragm, the appearance resembling that of carcinoma. If, however, the patient is tilted in order to allow the barium to flow back into the oesophagus the existence of a portion of the stomach above the diaphragm becomes apparent (Fig. 3). It is also sometimes necessary to increase the intra-abdominal pressure by compressing the abdomen or by instructing the patient to strain. It is interesting to note, however, that in two cases in our series it was found impossible to reproduce these appearances on every occasion a barium examination was made, no evidence of hiatal hernia or short oesophagus being obtained.

In this series of 31 cases of short oesophagus and thoracic stomach a partial stricture of the oesophagus was present in 26, and 15 patients showed also an oesophageal ulcer. Thus five patients had a short oesophagus and a thoracic stomach without stricture, though subsequently a stricture did develop in two. Carcinoma was found in the thoracic part of the stomach once, and simple ulcer once.

Oesophagitis was found in varying degree over a distance of about an inch (2.5 cm.) proximal to the constriction in the lower oesophagus. The mucosa was generally engorged with superficial erosions, and radiating streaks of greyish exudate were conspicuous. In some cases there were granulations simulating malignant fungations. Active peptic

ulcers had a flat yellowish-white base with a narrow bright-red margin, and greyish-white scars marked the sites of healed ulcers. Where pronounced spasm or secondary fibrosis was absent the constriction was readily distended, revealing the typical rugose mucosa in the supradiaphragmatic gastric pouch; in others spasm or fibrosis produced varying degrees of resistance to dilatation.

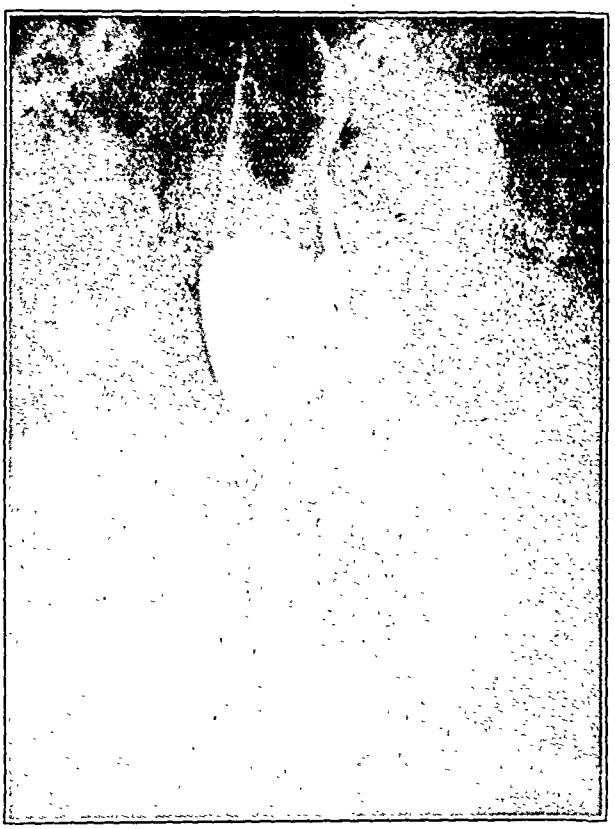

FIG. 2.—Radiograph taken in standing position showing partial stricture with irregular wall some distance above diaphragm, resembling carcinoma.

FIG. 3.—Radiograph taken while patient was tilted in order to allow the barium to flow into the oesophagus. A portion of stomach above the diaphragm is apparent.

The Short Oesophagus in Association with Other Conditions

Carcinoma in Thoracic Part of Stomach.—According to Dick and Hurst (1942) there is no unequivocal evidence that oesophageal ulcer undergoes malignant change. In 1934 Clerf and Manges reported an instance of cancer occurring not in the short oesophagus but in the thoracic stomach. Smithers (1945), reviewing the literature, quoted such a case recorded by Christiansen (1941) and another by Raven (1941), and added two of his own.

Case 3.—For three months before admission a woman aged 67 had progressive dysphagia until only fluids could be swallowed. Food was felt to stick at the lower end of the sternum and was accompanied by a burning sensation. Regurgitation was frequent, with blood present on several occasions. Appetite was very poor from early in the illness. A radiograph showed a short oesophagus and a stricture. A thoracic stomach was present in which there was a persistent ragged outline at one point. Oesophagoscopy revealed a stricture 27 cm. from the teeth, and a specimen taken for biopsy showed gastric mucosa infiltrated with adenocarcinoma. This patient died in another hospital, and no necropsy was made.

Peptic Ulcer in Stomach or Duodenum.—Seven out of 31 patients had a history of peptic ulceration of the stomach or duodenum.

Case 4.—A man aged 54 was admitted in February, 1941, because of haematemesis from a duodenal ulcer which had given rise to symptoms for three years. Between February, 1941, and July, 1943, he was readmitted on three occasions because of haematemesis. At the time of admission in 1943 there was much vomiting due to pylorospasm. Within a few days he began to complain of burning pain behind the sternum and to regurgitate solid food. A radiograph showed a thoracic stomach and a short oesophagus to be present along with an oesophageal ulcer and a tight stricture. For about four weeks all solids and much fluid were regurgitated. Thereafter he improved rapidly, and, while occasional dysphagia occurred, he remained well without dilatation until readmitted in December 1945, with a haematemesis which proved fatal. Post-mortem examination showed that the fatal bleeding had taken place from a duodenal ulcer, while the scar of a healed ulcer was observed in the oesophagus 5 cm. above the cardia. There was no stricture, and shortening of the oesophagus was not noted. As the pathologist had unfortunately not been informed of the radiological findings the oesophageal hiatus was not measured.

This case is of interest in that it demonstrated that extreme dysphagia lasting for several weeks was caused by spasm without organic stricture.

Dysphagia after Abdominal Operation.—In three of the cases in this series persistent dysphagia which had lasted for years developed within a few days of an abdominal operation.

Case 5.—A man aged 51 was operated on in July, 1943, for perforation of a duodenal ulcer. After operation continuous vomiting took place, for which gastro-enterostomy was performed six days later. Within a few days he felt food sticking at the lower end of the sternum. Pain was slight, of a burning character, and always at the same spot. These symptoms were at first intermittent, but dysphagia became very marked in October, 1943, and a barium swallow showed a short oesophagus, a thoracic stomach, an oesophageal ulcer, and stricture. Oesophagoscopy revealed a partial stricture 28 cm. from the teeth. No break of mucosa was seen and no biopsy was made. Apparently because it was felt that carcinoma could not be excluded, it was decided to give a course of deep therapy, which was soon discontinued at the radiologist's request

When seen in 1946 he had no pain, but still had to chew solid food very carefully. A radiograph again showed a short oesophagus, a thoracic stomach, an oesophageal ulcer, and stricture.

Case 6.—A woman aged 58 developed dysphagia three days after an operation for gall-stones in 1936. Food stuck at the lower end of the sternum, associated with pain in the epigastrium and left hypochondrium. It was worst about half an hour after food and was relieved by regurgitation, which occurred frequently. These symptoms were notably intermittent, even from meal to meal. *X*-ray examination in the upright position only revealed a stricture in the lower third of the oesophagus, while oesophagoscopy showed a "fungating growth" starting 30 cm. from the teeth and becoming obstructive near the cardia. No biopsy was made, and *x*-ray treatment for carcinoma was given. She was seen by us in 1946, when she was fairly well but required the passage of bougies at frequent intervals. Her pain, which was still present, was relieved by sodium bicarbonate. She had had slight haematemesis in 1945. A radiograph in 1946 disclosed a short oesophagus with ulcer, stricture, and thoracic stomach. Oesophagoscopy showed an ulcer proximal to the stricture 25 cm. from the teeth, and gastric mucosa was obtained on biopsy from the supradiaphragmatic pouch.

Case 7.—A man aged 37 was operated on for a perforated duodenal ulcer in 1940. Within a week of this he felt discomfort at the lower end of the sternum on swallowing solid food, which stuck momentarily at that site, but there was no regurgitation. A barium swallow in the upright position was stated to indicate nervous spasm. The symptoms continued intermittently till September, 1945, when he had a bout of severe substernal pain and marked dysphagia with regurgitation of solid food. A radiograph at this time showed a short oesophagus, a thoracic stomach, an oesophageal ulcer, and stricture. Oesophagoscopy revealed a stricture 32 cm. from the teeth and a short oesophagus. Biopsy was not made. Bougies were passed with good effect, and in April, 1946, he stated that he was able to swallow most things if well masticated.

Only three instances of persistent dysphagia appearing first after operation were found in the hospital records over 10 years. Oesophageal ulcer and benign stricture were present, associated in every case with a short oesophagus and a thoracic stomach.

Pregnancy

The occurrence of dysphagia in the last three months of pregnancy has been described by Vinson (1923, 1924). The initial symptoms were "vomiting" and pain behind the lower end of the sternum, followed within a day or two by dysphagia, for which the passage of bougies was required. Haematemesis was common and even proved fatal in some cases. Vinson believed that these patients developed an oesophageal stricture because of frequent vomiting. From his records dysphagia was still present months after the onset.

In five of the present series the onset of oesophageal symptoms occurred in the later months of pregnancy.

Case 8.—A woman of 36 developed dysphagia in the sixth month of pregnancy. It was accompanied by a burning pain at the lower end of the sternum which passed through to the back. Symptoms intermitted with almost complete relief for several weeks at a time. In 1933 radium treatment was given for carcinoma of the oesophagus, the diagnosis being based on an oesophagoscopic examination which showed an "ulcerated growth" 30 cm. from the teeth and an obstruction to barium at that level. No biopsy was made. After treatment symptoms continued as before, but the patient's general condition remained quite good. In 1946 *x*-ray examination revealed a short oesophagus with ulcer, and oesophagoscopy showed the oesophagus to be dilated, with a conical approach to a fibrous stricture 26 cm. from the teeth. A whitish scar was visible on the posterior wall at the entrance to the stricture.

Case 9.—Just before the birth of her baby in 1940 a woman aged 36 felt that food stuck at the lower end of the sternum; there was no pain. Regurgitation was frequent at first. In 1940 *x*-ray examination in the upright position revealed stricture of the lower third of the oesophagus, and oesophagoscopy showed an annular obstruction 31 cm. from the teeth without breach of mucosa. No biopsy was made. Cancer was diagnosed and *x*-ray therapy was given. Some months later the stricture was dilated by bougies with complete relief. When seen in 1946 she was very well and could eat anything without dysphagia provided she chewed it thoroughly and had no emotional disturbance. A radiograph revealed a short oesophagus, a thoracic stomach, an oesophageal stricture, and an ulcer.

Case 10.—A woman aged 38, in the seventh month of pregnancy in 1942, quite suddenly felt solid food stick at the lower end of the sternum. At the same time she was conscious of a burning pain at this site immediately after taking food. Symptoms were rather worse after delivery and she lost weight. Regurgitation was frequent and gave relief. *X*-ray examination showed that barium was held up 7 cm. above the diaphragm, where there was a smooth stricture. Below this there was a globular enlargement in which mucosal markings were present, continuous with those of the main body of the stomach below the diaphragm, but no ulcer was seen. Oesophagoscopy was not done. In 1946 she was fairly well, but had to be careful what she ate. *X*-ray findings were similar to those in 1942.

Case 11.—This patient, aged 39, developed difficulty in swallowing solid food during the last weeks of pregnancy in 1944. Regurgitation was frequent but there was no pain. *X*-ray examination revealed a short oesophagus, a thoracic stomach, a small ulcer of the oesophagus, and a stricture. In April, 1946, she still had difficulty in swallowing.

Case 12.—This woman, at the age of 41 and during the last two months of pregnancy, felt a burning pain in the mid-sternal region which radiated to the back. It started 10 minutes after taking solid food, but was also present at night, when it was so severe that she could not lie flat. There was no regurgitation, but food tended to stick at the site of the pain. Nineteen years after the onset of symptoms, which were intermittent, she suddenly began to regurgitate all food and drink. A barium swallow showed complete obstruction in the lower third of the oesophagus. The diagnosis of foreign body was made and a piece of orange was removed from the lower end of the gullet with immediate relief. When seen in April, 1946, she said that some pain and dysphagia were still present. *X*-ray examination revealed a short oesophagus and a thoracic stomach, with partial stricture of the oesophagus, but no ulcer could be demonstrated.

The findings in these five patients are summarized in Table III. All the patients were over 35 and symptoms started between the fifth and last months of pregnancy.

TABLE III.—*Dysphagia in Pregnancy*

Case No.	Dysphagia	Pain	Month of Pregnancy	Age at Onset	Duration of Symptoms (Years)	*X*-ray Findings in 1946
8	+	+	6	36	13	S.O., T.S., Str., U.
9	+	0	9	36	6	S.O., T.S., Str., U.
10	+	+	7	38	4	S.O., T.S., Str.
11	+	0	9	39	2	S.O., T.S., Str., U.
12	+	+	7	41	19	S.O., T.S., Str.

S.O. = Short oesophagus. T.S. = Thoracic stomach. Str. = Stricture. U. = Ulcer.

The duration of symptoms ranged from 2 to 19 years. Dysphagia was present in all, and pain behind the lower end of sternum in three. *X*-ray examination revealed short oesophagus, thoracic stomach, and oesophageal stricture in all, with ulcer also present in three.

Vinson attributed the stricture to the presence of gastric juice in the oesophagus resulting from excessive vomiting, but the development of dysphagia and regurgitation in our

series was in no instance preceded by vomiting. On the facts it seems reasonable to argue that the development of the stricture during pregnancy is due to increased intra-abdominal pressure at that time causing reflux of gastric juice into the oesophagus through a cardia incompetent because of its position in the thorax. The age of the patients in relation to pregnancy, the youngest being 36, is possibly another factor predisposing to laxity of the oesophageal hiatus. Allison, Johnstone, and Royce (1943) describe a similar case in which dysphagia began during pregnancy and a short oesophagus was found to be present, but they make no comment on the association.

Pathology

Since the earlier reports, summarized by Findlay and Brown Kelly (1931), there has been singularly little addition to the pathological knowledge. Morison (1930) described a further clear-cut case.

In this series, two patients died (one of haemorrhage from a duodenal ulcer and the other of cancer of the colon) and post-mortem examinations were made. The description of the findings in Case 4 has already been given.

Case 13.—A woman aged 62 was admitted to hospital because of bleeding from the rectum due to carcinoma of the pelvic colon. She gave a 40-year history of regurgitation of solid food which stuck at the lower end of the sternum. "No other information was available from records. *X*-ray examination showed a short oesophagus, a large thoracic stomach, and a partial oesophageal stricture, but no ulcer was seen. This patient subsequently died, and at necropsy the oesophagus was not short, since the measurement from the top of the thyroid cartilage to the cardia was 30 cm. The hiatus, however, measured 2 in. (5 cm.) in diameter, the oesophagus being placed centrally and attached loosely to it by a fibrous diaphragm.

Unfortunately in Case 4 no special search was made and the oesophageal hiatus was not measured, but there was at least no pronounced shortening of the oesophagus and no part of the stomach was found in the thorax. The findings in Case 13 were also unexpected in that here again none of the stomach was in the thorax and there was no shortening of the oesophagus—this in spite of the unequivocal radiological evidence to the contrary (Harrington, 1940). One is therefore forced to the conclusion that even after years of dysphagia and regurgitation the hiatal hernia may remain unfixed or sliding, while the shortening of the oesophagus must be attributed to spasm. It should be noted, however, that in neither of these cases was there a fibrous stricture.

In an exhaustive discussion Smithers (1945) reached the conclusion that the initial lesion is a congenital or acquired weakness of the oesophageal hiatal ring with herniation of the cardiac end of the stomach followed by passage of gastric juice into the oesophagus. Contraction of the longitudinal muscle fibres is thereby provoked with production of "shortening" of the oesophagus. Support for this view is drawn from the work of Gilbert, Dey, and Rall (1946), who stimulated the vagi of cats electrically and observed contraction of the oesophagus, with drawing upwards of the cardia through the oesophageal orifice. We have ourselves noted in two very recent patients (not included in this series) at one time radiological appearances typical of large para-oesophageal hernia and a few weeks later those of hiatal hernia with short oesophagus. This would make it very difficult to accept the hypothesis of congenital shortening of the oesophagus.

On the other hand the post-mortem observations of the earlier workers and recent work of Allison (1948), who excised the fibrous oesophageal strictures, show that in some patients, presumably after ulceration, the oesophagus becomes permanently shortened by cicatricial contraction.

Prognosis and Treatment

The majority of patients in this series were able to lead a reasonably comfortable and normal life in spite of persistence of oesophageal symptoms, provided they exercised care in the choice of diet and masticated their food thoroughly. From time to time a number required the passage of bougies. The upright position in bed to minimize the reflux of acid, and the use of alkaline powders, were often helpful. One patient seemed to have made a complete recovery, but refused to have a re-examination with barium. One patient was found to have adenocarcinoma of the thoracic stomach and died in another hospital. The other two deaths in this series were due to a coexistent duodenal ulcer (haemorrhage) and to carcinoma of the colon respectively.

It is of interest that we were able, after an interval of 17 years, to re-examine two of the patients originally reported on by Findlay and Brown Kelly in the Royal Hospital for Sick Children, Glasgow, when one of us was house-physician to Professor Findlay. One was a woman now aged 25, small and slightly built, who was in good health and had served in the A.T.S. She confessed that at times she had dysphagia and regurgitation, but apparently had had no difficulty in concealing this from the Army authorities. Barium examination revealed a short oesophagus, a thoracic stomach, and a partial stricture. The other patient was a sturdy youth of 18 who occasionally felt food stick at the lower end of the sternum. *X*-ray examination gave a similar picture.

Summary

Over a period of 10 years dysphagia in 26 patients was found to be due to simple ulcer or stricture of the lower end of the gullet, accompanied by *x*-ray appearances of gastric hiatal hernia and shortening of the oesophagus. Over the same period cancer in the lower third and achalasia caused dysphagia in 80 and 31 instances respectively.

The diagnosis was not often considered, and proof was obtained only by radiology, using a special technique with, on occasion, oesophagoscopy and biopsy.

Dysphagia and ulcer pain developed during the later months of pregnancy in five patients and immediately following abdominal operation in three.

In five patients there were no oesophageal symptoms—three were admitted because of massive haematemesis, one because of anaemia, and the fifth gave a long history of pain and flatulence for which her gall-bladder had been removed without relief.

Congenital or "acquired" weakness of the oesophageal ring is common, allowing of a small sliding hiatal hernia without symptoms. It is considered that only in a minority of people does oesophageal ulcer develop. A rise of intra-abdominal pressure in pregnancy would seem to be one factor concerned. Oesophageal ulcer was not encountered in the absence of hiatal hernia and short oesophagus.

We would like to thank many colleagues in the Western Infirmary who have allowed us access to their patients and to their case records.

TRILENE ANALGESIA IN PAEDIATRIC PRACTICE

BY

J. THOMSON, M.B., F.R.C.P.Ed.

Paediatric Physician, Royal Infirmary, Dundee; Lecturer-in-Charge, Medical Diseases of Children, University of St. Andrews

D. A. I. GREWAR, M.B., Ch.B.

Clinical Assistant, Royal Infirmary, Dundee

AND

J. G. GROUNDS, M.B., Ch.B.

House-physician, Royal Infirmary, Dundee

Various minor diagnostic procedures in paediatrics, such as venepuncture, lumbar puncture, marrow puncture, testing electrical reactions of muscles, abdominal palpation, and chest exploration, cause apprehension and discomfort, often sufficient to render a child uncooperative or even actively resistant. Many other painful and uncomfortable undertakings occur in the course of treatment, such as intravenous injections and burn and wound dressings.

It is possible to diminish apprehension with such sedatives as chloral hydrate or "seconal" and still leave the patient co-operative; but often at the first appreciation of pain the child becomes resistant. The use of anaesthesia or local analgesia would seem to be justified where there is likely to be more than trivial discomfort or where it is essential that the patient should remain still and not resist. General anaesthesia eventually eliminates the patient's resistance but deprives us of his co-operation, and is not without a certain minimal risk. Local analgesia, with its attendant first stab of pain, often renders the child apprehensive, so that he becomes restless and uncooperative.

It occurred to one of us (J. T.) that analgesia produced by a simple inhaler might overcome the disadvantages of sedatives and of anaesthesia. In this communication the apparatus, indications for its use, the technique of administration, and the results obtained in a series of 60 consecutive administrations are described.

Apparatus

The apparatus used was the Blease inhaler. This is a simple draw-over type of inhaler, which can give three concentrations of "trilene" (trichlorethylene) suitable for analgesia and an additional one for anaesthesia by adjusting a simple screw setting. On occasions when induction was slow it was necessary to increase the concentration to "anaesthesia." The only modification required in the standard equipment was the provision of a small face-mask. We used the smallest obtainable (B.O.C. type, small size). At times an even smaller size would have been an advantage.

Indications.—We define analgesia as the loss of sensation of pain without loss of consciousness. The apparatus was used when a diagnostic or therapeutic measure was likely to cause pain, discomfort, or undue apprehension, and where formerly we would have employed sedatives or local or general anaesthesia. When analgesia is desirable, trilene would seem to have no special contraindication.

Our series of 60 cases represents a cross-section of patients admitted to a children's medical ward for investigation and treatment. Analgesia was given for lumbar puncture (34 cases), cisternal puncture (3 cases), venepuncture (7 cases), chest aspiration (8 cases), marrow puncture (3 cases), burn and wound dressings (3 cases); and in one case each for abdominal palpation and electrical reactions.

Age.—The ages ranged from 8 months to 11 years. In infants under 9 months old inhalational analgesia has little to recommend it. We found its greatest use in children over 1 year old. In those in the group aged 1 to 5 years it prevents resistance; and in those over 5 years it will also often secure actual co-operation.

State of Health.—The state of health varied from the acutely ill newly admitted child to the chronically ill case from the waiting-list for investigation or the comparatively healthy convalescent.

Procedure to be Undertaken.—The predominant symptom, or the suspected lesion, along with the diagnostic procedure undertaken in the various cases, is shown in the Table. In the course of treatment, intravenous injections, toilet of burns, suture of lacerations, and burn and wound re-dressings were all carried out under analgesia.

Administration

No premedication was given, and analgesia was induced without special regard to the interval since the last meal. One patient received trilene as early as five minutes after a meal without untoward effect. Several have been given trilene soon after meals, because of urgency in getting samples for laboratory examination. It is not suggested that a recent meal should be ignored, but when circumstances warrant haste trilene analgesia can justifiably be employed soon after a meal. The child, if old enough to understand, is told the purpose of the inhaler and asked to take extra deep breaths if he should feel anything hurt. The mask is applied and a conversation is kept up with the child to allay fear and encourage regular breathing. The older children, aged 5 to 11, were more or less co-operative during the administration and responded to the instruction to take regular deep breaths, usually becoming analgesic in two or three minutes. The younger children struggled and cried in some instances, but after a few deep breaths, associated with the effort of crying, they quieted down, became analgesic, and were usually drowsy. Coughing and spluttering were unusual. When we had become more conversant with the signs of analgesia (see below), if induction seemed a little slow the control screw was turned to "anaesthesia" and returned to "maximum analgesia" when analgesia was obtained. No increase in concentration of trilene was required for older children. Indeed, the younger ones were usually more resistant; but

this may have been due to the difficulty in getting a snugly fitting mask which would allow an effective concentration of trilene to be inhaled.

Once satisfactory analgesia was obtained, the finger was removed from the air port over the facepiece, thus permitting the patient to breathe air. The port was again occluded if analgesia diminished.

The signs indicating effective analgesia were not defined clearly enough to allow any hard-and-fast rules to be laid down, but the following observations were made when analgesia was effective: the breathing was regular, the eyelids were closed, and there was diminishing response to the eyelid reflexes. The patient was drowsy, but, if old enough, readily, almost automatically, responded to requests such as, "Turn on your side" or "Put your arm out."

When ether was used in skin preparation the absence of resentment to its coldness was a good indication that analgesia was satisfactory.

If the administration was continued with the control screw at "maximum analgesia" some cases showed a little increased motor activity, suggesting that the second stage of anaesthesia had been reached. Administration was stopped at this point and the stage of analgesia and drowsiness returned. Where the operation was to be of short duration, administration was continued until the painful stimulus—for example, the prick of the needle—was effected; then the facepiece was removed and the residual analgesia usually afforded enough time for the completion of the procedure. In one case not in this age group an intelligent 12-year-old boy successfully administered trilene to himself to the stage of analgesia, during which lumbar puncture and cerebrospinal fluid manometry were carried out.

In five cases tachypnoea developed, and the administration was stopped. However, subsequent events showed that the onset of tachypnoea corresponded with a satisfactory degree of analgesia.

Observations

We all gained the impression that trilene facilitated the performance of these minor procedures for both patient and operator. This conclusion, so far as it concerns the patient, was based upon objective findings in the younger children, and in the older children upon both objective and subjective findings.

Before questioning the older children a day was usually allowed to elapse, because when still analgesic the child was obviously very amenable to suggestion. Although no set series of questions was asked, it was clear that memory for the procedure was hazy and the child would state that no pain was felt.

Lack of Pain.—No attempt was made to estimate the degree of analgesia quantitatively. However, the following observations led us to conclude that in every case pain was either abolished or greatly diminished. (1) There was never any cry caused by pain or any noticeable vocal or motor response due to the painful stimulus. (2) When subsequent similar procedures were indicated the children showed less apprehension. (3) The painful stimulus evoked little or no resistance—e.g., there was much less extending of the spine when the needle entered the skin for lumbar puncture, and the child was much more easily held in position.

Co-operation or Lack of Resistance.—Active co-operation or at least lack of resistance was apparent when some unusual position had to be maintained. At lumbar puncture the patient lay still and relaxed, allowing full flexion of the spine. In one girl, aged 8, we twice easily performed lumbar puncture under trilene analgesia and later transferred her to another hospital, where a lumbar

Satisfactory analgesia 98%

Inhaler of value in 98%

puncture, attempted without analgesia, had to be abandoned because of resistance. In another case, a child who had shown violent opposition submitted readily to a difficult intravenous injection after a few breaths into the trilene inhaler. In a case in which electrical reactions were investigated in a child of 3, we first attempted it without analgesia, but at the first stimulus she became restless. Satisfactory assessment of her reactions could be made only after analgesia had been induced.

Relation to State of Health.—The acutely ill children were more easily made analgesic, but otherwise showed no different response and suffered no more after-effects from the trilene than the chronically ill or convalescent. Where development of empyema was suspected, chest aspiration was effected easily and comfortably under trilene, and the patient suffered no ill effects from it. Trilene in low concentration is practically non-irritant to the respiratory passages. This suggests that the presence of acute or subacute inflammatory lesions of the chest may be no contraindication to trilene analgesia. No cases of primary liver disease occurred in our series, but as trilene has only a transient slight hepatotoxic effect (Armstrong, 1947) it would seem quite justifiable to use it for the short period required unless very extensive liver damage was suspected.

After-effects.—In this series no untoward effects resulted from the administration of trilene analgesia, apart from vomiting. This occurred in only one patient, who had had a large meal half an hour before trilene was administered. The child was not seriously ill or toxic, and no explanation was forthcoming why she had vomited. Vomiting did not occur in any other case in the series. All the children were able to take their next meal at the usual time and did not require additional nursing. Post-analgesic drowsiness was not infrequent (72% of total cases). It lasted from a quarter of an hour to two hours. The child awoke as from natural sleep. It was regarded as one of the advantages that a child should have this short sleep after an unusual experience, as he awoke with apparent amnesia for it.

Failure of Analgesia.—This was observed in one case, that of an infant aged 14 months. The child cried and struggled throughout. This was thought to be due to a poorly fitting face-mask.

Advantages and Disadvantages

Advantages.—(1) The apparatus is simple, safe to use, and inexpensive to maintain. (2) Administration of the analgesia presents no difficulty and takes no longer than local analgesia. (3) Trilene analgesia causes the patient no discomfort. Apprehension is greatly diminished and pain is abolished or greatly reduced. (4) Trilene analgesia affords enough scope for the performance of most of the painful diagnostic and therapeutic procedures in paediatrics. It avoids having to make the choice between full anaesthesia with its risk and possible upset, and no anaesthesia with its safety but greater discomfort. (5) Trauma, physical and psychological, is minimized. (6) The diagnostic and therapeutic procedure can be carried out more quickly, adequately, and deftly, and asepsis is more readily maintained. (7) Satisfactory analgesia allows more comprehensive investigation to be undertaken. (8) The post-analgesic effects include a beneficial period of drowsiness associated with apparent amnesia for the procedure. Nausea is infrequent and meals can be resumed in nearly every case when the patient awakes.

Disadvantages.—(1) The point at which analgesia becomes effective is not easy to appreciate. (2) There is no uniformity in the response to a given concentration of trilene, and the same vigilance must be observed as when administering any anaesthetic. (3) Tachypnoea may occur.

Conclusions

Analgesia which is safe, easily induced and controlled, and devoid of untoward after-effects would appear to be desirable in many of the painful or frightening diagnostic and minor therapeutic procedures in medical paediatric practice.

Local analgesia produced by procaine or similar substances is safe, but causes initial pain and thereafter apprehension and resistance.

Drugs such as chloral hydrate and the barbiturates have not sufficient analgesic effects. Trilene is one of the safest analgesic agents (Ostlere, 1948). It is well taken and well tolerated by children. When administered from an inhaler of the Blease type it produces satisfactory analgesia (98% in this series). It allowed a variety of procedures to be carried out without pain or resistance, or the inconvenience and risk of general anaesthesia.

Psychological upsets are greatly diminished, thus allowing frequent investigations of a disturbing nature to be carried out.

Apart from occasional post-analgesic vomiting (2%) trilene produced no undesirable after-effects. Trilene given with an inhaler of the Blease type secures analgesia more effectively and with a greater margin of safety than any other method with which we are familiar.

Summary

The need for analgesia of short duration in medical paediatrics is discussed.

Trilene analgesia in 60 consecutive cases is analysed. Satisfactory analgesia was obtained in 98%. Beneficial drowsiness occurred in 72%. Tachypnoea occurred in 8%, but analgesia was already present. Psychological benefits are noted.

It is claimed that trilene from a Blease-type inhaler produces satisfactory analgesia for use in medical paediatric practice.

Ostlere, G. (1948). *British Medical Journal*, 1, 195.

The report of the River Pollution Prevention Subcommittee of the Central Advisory Water Committee was published recently by the Ministry of Health. The subcommittee was asked to investigate measures for strengthening the law regarding the prevention of pollution of rivers and streams. Its recommendations mark a further stage in the steps proposed for safeguarding and improving the conditions of rivers in England and Wales. The new River Boards, which are now being set up under the River Boards Act, 1948, will provide a new administrative organization based on natural catchment areas instead of local government areas. The next stage is to equip these boards with up-to-date and effective legal powers. The subcommittee considers that the Rivers Pollution Prevention Act, 1876, which is the principal Act now in force, needs considerable revision and strengthening. One of its main recommendations is that effluents discharging into a river or stream should be required to comply with standards prescribed by the River Boards. The standards would be prescribed by by-laws, subject to confirmation by the Minister of Health under a procedure which would give those affected an opportunity to raise objections and to be heard in support of them. Under the Act of 1876 legal proceedings in respect of pollution by trade and mining wastes may be taken only with the consent of the Minister of Health. The subcommittee recommends that once standards have been prescribed consent should not be necessary in the case of failure to comply with a standard, since the effect of the standard on industrial interests will have been considered when the standard was applied.

LEUCOTOMY AND HYPERTENSION

A CASE REPORT

BY

R. W. TIBBETTS, M.A., B.M., D.P.M.

(From the Psychiatric Department, St. George's Hospital, S.W.1)

The following case raises points of theoretical and practical interest, with special reference to the psychosomatic relationships of hypertension.

Case Report

A housewife, then aged 54, was first seen in the psychiatric out-patient department of St. George's Hospital by Dr. Desmond Curran in September, 1947. The presenting symptoms were suicidal depression, intense headaches, and deterioration of vision of three years' duration. A few weeks later she was admitted under Dr. Curran's care into the St. George's Psychiatric Unit at the Atkinson Morley Hospital, Wimbledon.

She is said to have been a woman of active but even temperament. Her personal history, free as it was from abnormal stress, instability, or disharmony, contributes little to an understanding of the case. Marital relations have been good and her three children enjoy good health. Pregnancies and puerperia were uncomplicated. The family history is significant only in so far as the father was asthmatic and one of eleven siblings committed suicide at the age of 21, in the face of considerable stress.

Onset

Her physical and mental health was good until 1944, when her spontaneity and outside interests began to decrease. Intense stabbing supraorbital headaches were increasingly frequent and her menses became irregular. Her visual acuity was decreasing and there were multiple inconsistent symptoms of a hysterical kind. Depression, accompanied by headache and worse in the morning, became so severe that suicidal preoccupation was almost constant. Her threats completely disorganized home life, and on four occasions she made material suicidal preparations or attempts. Even making allowance for histrionic features, the underlying risk was considerable.

In 1946 she was admitted to Dorking Cottage Hospital under Dr. Brice-Smith, who, with the aid of intravenous and retrograde pyelograms and blood-urea estimations, was able to exclude a renal basis for the hypertension. At this stage she was referred to Dr. Strauss at the department of psychological medicine, St. Bartholomew's Hospital. On the organic side arteriosclerosis, hypertension, and a small retinal haemorrhage were noted, while phobias and other neurotic symptoms were prominent. Some of these were alleviated by a narcoanalysis performed by Dr. Jonathan Gould, but the depression persisted. The intractability and severity of the depression were such that certain risks were justified, and it was agreed that electric convulsion therapy should be given a trial. Seventeen treatments were given in two courses over a long period, but the slight improvements were never sustained. Due consideration being given to the operative risk with an arteriosclerotic subject, Dr. Strauss and Dr. Gould concurred that the indications were in favour of prefrontal leucotomy.

At the Atkinson Morley Hospital her blood pressure was observed closely for three weeks. At its most favourable it was of the order 170/100. It was usually considerably higher and there were frequent hypertensive attacks associated with intense headache, with the blood pressure as high as 260/160. Dr. Gerald Parsons-Smith reported: "This patient has severe arteriosclerosis with hypertensive heart disease. The hypertension is at present in a labile stage and has not become fixed at the high figures of 260/160, which will eventually become the position. Examination of the fundi confirms the severe arterial changes. . . ." Clinically there was slight cardiac enlargement and an accentuated aortic second sound. There was no papilloedema, but the retinal haemorrhage was still visible. The blood urea was 28 mg. per 100 ml. All other relevant special investigations yielded insignificant results.

From the mental standpoint she was profoundly tense and depressed and moderately retarded. She made one suicidal gesture in the ward and was constantly on full precautions. Sleep and appetite were poor. There was little self-reproach, and she was not deluded. Her recent memory, as might have been expected, was patchy, but on the whole there was nothing to indicate organic cerebral deterioration.

Treatments which had proved unavailing at various hospitals included pethidine, nicotinic acid, oestrin preparations, venesection, strong sedation, psychotherapy, and E.C.T. Sympathectomy had been considered to be contraindicated. Dr. Curran agreed that leucotomy should be recommended, and the risks were explained to her husband. Mr. Wylie McKissock generously undertook to perform the operation, and bilateral prefrontal leucotomy was performed on October 29, 1947, the approach being that described elsewhere (McKissock, 1943). Very severe arterial haemorrhage occurred on the left side, but eventually the flow was controlled with a tantalum clip.

Post-operative History

The patient's general condition in the immediate post-operative phase, while never critical, gave rise to concern for about two days. Her pulse remained regular and the blood pressure, after the initial shock, fluctuated slightly around 140/80. She was incontinent for about a week, and from the mental standpoint she was free from tension and depression, but was confused and disorientated. After three weeks she was out of bed, but still apt to be confused and to confabulate. She was cheerful, greedy, fatuous, and anergic, and was inclined, even more than most post-leucotomy patients, to huddle round the fire and radiators. On one occasion a syncopal (not epileptiform) attack occurred, and in this her blood pressure fell to 80/40. A haemoglobin level of 70%, which responded to iron treatment, may have been contributory. Two months after the operation her behaviour was greatly improved and she was noted as being cheerful, sociable, and helpful in the ward. Her witticisms were not always fully apt and, with a set occupational task, she proved incapable of long-sustained attention. She was eating and sleeping well and gaining weight.

The next six weeks were spent at Roffey Park Rehabilitation Centre, where, in such a favourable environment, she continued to improve, especially from the occupational standpoint. Frequently recorded blood-pressure readings were always between 160/90 and 140/80. On one occasion an epileptiform attack occurred and subsequently she received a 1-gr. (65-mg.) tablet of phenobarbitone twice a day.

Since that time the patient and her husband have been seen about every two months, the last attendance being 16 months after the operation. The following are summaries of the findings.

1. There have been no headaches worthy of note.

2. The prevailing mood is cheerful and she has been virtually free from tension or depression. The personality changes, as betrayed by occasional outspoken remarks or carefree domestic attitudes and slight limitation of foresight, are scarcely evident as such to the family. She works harder than many and the home is well run. This contrasts with her almost total social and domestic incapacity during her illness.

3. She has had three attacks of (almost certainly) minor epilepsy related to inconsistent taking of phenobarbitone. The last attack was in April, 1948.

4. Precipitancy and occasional enuresis have occurred, but there has been no enuresis in the last two months.

5. She has continued to gain weight—from about 8 st. to 12 st. (50.8 to 76.2 kg.)—since the operation. Her friends and family claim to like her "comfortable figure," but she is definitely obese.

6. The menstrual periods have ceased entirely since the operation.

7. The most striking change is that the blood pressure has always been within the range 160/100 to 140/95. There has been no tendency for it to rise month by month.

8. She was re-examined by Dr. Parsons-Smith 15 months after the operation. He states: "There has been quite a remarkable change in this patient's general medical condition since I saw her in 1947. Recently she has had no symptoms referable to her cardiovascular state, which is all the more striking since she has gained 4 st. (25.4 kg.) in weight. She still has well-marked arteriosclerotic changes, but the fundus is free from exudates and haemorrhage and there is no papilloedema. . . ." The apex beat was in the fifth space in the same position as before, 4½ in. (11.4 cm.) from the mid-sternal line, but there were no other abnormal physical signs.

9. *Special Investigations (January, 1949, 15 months after operation).—Electrocardiography:*—Unfortunately no pre-operative record was available for comparison. Taking this into account, the record at this time was not significantly abnormal. *Electroencephalography:*—"The E.E.G. recorded on this date was very abnormal. The tips of both frontal lobes showed flat records, but elsewhere irregular slow waves were seen in all leads. These were occasionally organized into short rhythms characteristic of epileptic discharges." The *blood urea* was 25 mg. per 100 ml. A radiograph of the chest confirmed slight *cardiac enlargement*, but there was no change from the pre-operative picture.

10. Mrs. Petrie, reassessing the patient eight months after the operation, reported the I.Q. as 109 (Wechsler-Bellevue scale). The gain of 10 points over the pre-operative level was largely a measure of increased co-operation.

11. The tendency to improve since the leucotomy still seems to be operative.

Discussion

There can be little doubt that without the operation the patient was faced with a future of almost constant suffering until death occurred from suicide or cardiovascular complications. The price which has been paid in personality change is familiar in quality but small in degree; progressive hypertensive changes would probably have affected the personality more adversely.

The final cessation of the menstrual periods and the obesity (greater than one might have a right to expect in terms of energy output and food intake) point to endocrine or metabolic changes, about the exact nature of which we can only speculate. The craving for heat, which we have observed more than once after leucotomy, is interesting. It has seemed to us to have a more fundamental basis than mere anergia or hedonism, and, clinically, hypothyroidism has not been indicated. The fact that in monkeys increased heat loss has been shown to follow experimental ablation of area 13 is worth noting (Livingston, Fulton, *et al.*, 1948). It is thought that this may possibly be due to reduction in the amount of peripheral sympathetic activity; in this context it is interesting to note that, in spite of full precautions, our patient developed a bedsore on one buttock after the operation. This has occurred in no other leucotomy patient in our experience.

The main interest in this case, however, attaches to the fall and the greatly increased stability of the blood pressure. Abrupt changes in blood pressure are commonly observed during the operation, and Freeman and Watts (1942) write: "On a number of occasions we have observed a precipitate drop in the blood pressure following incision of the subcortical white matter on one side and then an almost equally abrupt elevation, sometimes amounting to as much as 60 or 80 points, as the other side was operated upon."

In the majority of patients there is little permanent difference between the blood-pressure readings after operation and those recorded during the illness. Where, however, a high degree of nervous tension, in association with a raised blood pressure, existed before the operation, and where this tension is relaxed afterwards, there is a general tendency for the post-operative readings to remain at significantly lower levels. The tendency for the blood pressure to fail to reach the previous high peaks after leucotomy is best seen in frankly hypertensive patients; Freeman and Watts (1942) have described two such cases. Both of these women were suffering from agitated depression, and the relevant facts were:

	B.P. Before Leucotomy	B.P. After Leucotomy
Case A (aged 59)	184/110–222/128	190/105–195/110 (3-year follow-up)
Case B (aged 66)	Around 220/110	130/70–155/80 in hospital, and round 195/75 with full activity

The findings in both these cases are comparable with but less pronounced than those in the case reported above.

Three theoretical possibilities suggest themselves as explanations for the sustained reduction and the increased stability of blood pressure:

(*a*) Decreased physical activity after operation. This is not borne out by our patient, whose pre-operative readings were taken in bed.

(*b*) That the changes are due to interference with localized anatomical areas particularly concerned with automatic function. Evidence, largely inspired by the work of Fulton in America, points particularly to area 13, and to a less extent to area 14 (Stanley and Jaynes, 1949) on the orbital surface of the frontal lobe; the rostral part of the cingulate gyrus (area 24) is also suspect. While these areas are usually avoided in the performance of prefrontal leucotomy they have at times been involved.

Smith (1945), in stimulating the rostral part of the cingulate gyrus in monkeys, produced, among other changes, a significant rise in blood pressure without alteration in the cardiac rate. Ward (1948) described personality changes in the monkey after ablation of this area, and these changes are in some ways comparable to those which may be seen in man after leucotomy. Attention, however, has centred mainly on the orbital surface of the frontal lobe.

Changes in blood pressure (usually a rise), together with inhibition of respiration and decrease in gastric tonus, have been produced in animals by stimulating an area near the olfactory tract (Bailey and Sweet, 1940; Delgado and Livingston, 1948). In the monkey the blood-pressure responses are still operative if the vagi are cut and adrenals removed (Livingston, Fulton, *et al.*, 1948). More recently experiments have been carried out (Livingston, Chapman, and Livingston, 1948) in which, under moderate thiopentone anaesthesia, the orbital surfaces of leucotomy patients were stimulated before the operation. A gradual but consistent and significant rise in blood pressure followed stimulation, and it was shown that this was not causally related to the inhibition of respiration, which also occurred.

It is worth noting that in our patient none of the hyperactivity described in monkeys in relation to lesions of area 13 was seen (Livingston, Fulton, *et al.*, 1948; Ruch and Shenkin, 1943); hyperphagia, however, was certainly evident at first. The whole issue is of course obscured by our inexact knowledge of the extent of the lesion; in view of the haemorrhage this may have been considerable.

(*c*) The third approach assumes a close relationship between the mental tension and the raised blood pressure, so that a decrease in the one is accompanied *pari passu* by a fall in the other. This seems probable on general grounds and in view of the fall in blood pressure sometimes seen after patients who are both hypertensive and depressed have received electric convulsion treatment. In our present state of knowledge we are at a loss to know whether to think in terms of pressor substances or thalamo-frontal radiations, or a combination of the two.

In the selection of the small group of similar cases which might be helped by leucotomy the following criteria are suggested tentatively: (1) The mental state should be such as to call for leucotomy irrespective of the hypertension, and the mental tension should be pathologically high. (2) Every reasonable form of alternative treatment should have been tried without sustained response. (3) The outlook without leucotomy should be bad enough to make all concerned prepared to face a considerable operative risk. (4) Intellectual deterioration should be negligible. (5) The hypertension should be labile, as determined, if necessary, by the intravenous injection of sodium amytal. The arteries should preferably be in a healthier state than in the above case and there should never have been any indication of heart failure. (6) The renal function should be completely satisfactory.

Summary

A case is reported of prefrontal leucotomy performed on a hypertensive patient suffering from severe and intractable depression, the onset of which was associated with the climacteric.

Blood-pressure readings previously ranging between 170/100 and 260/160 have over the 16 months since the operation remained stabilized between 140/95 and 160/100. A retinal haemorrhage seen before the operation is no longer evident.

Possible explanations for these findings and for others which may be related to autonomic functions are discussed.

The disappearance of symptoms and the very great improvement in the domestic situation are considered to outweigh the personality changes and other complications.

Suggestions are made concerning the indications for performing prefrontal leucotomy where hypertension is one of the factors.

I am indebted to all those mentioned in the text for their help, and more particularly to Dr. Desmond Curran for criticism and encouragement and to Dr. Hazel Liddell for the use of her original notes on the case.

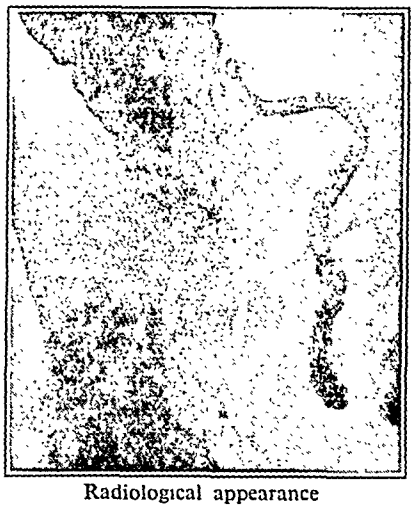
Speaking at a conference on home helps recently, Dr. Peters, Deputy Chief Medical Officer, Department of Health for Scotland, said that though the hospital and specialist services might be the most costly and the most spectacular part of the National Health Service a great deal of its work would be stultified if it could not be followed by continued care in the home. Socio-medical services were of the utmost value in helping to keep the family together and preventing it from being broken up, as it so often could be, by the sickness or disability of one of the parents or bread-winners. The home help should be looked on as a member of a team, along with the family doctor, the health visitor and the district nurse, which could do a great deal towards alleviating suffering and anxiety. She was not a nurse, although occasionally her duties might have to extend to some personal attention, but she was a trained member of a team of social workers whose job it was to help and strengthen the home. Some authorities were already reporting remarkable success in their efforts to supply home helps. The home-help arrangements could be one of the most important and most rewarding parts of the whole National Health Service.



Medical Memorandum

A Shot-filled Appendix

Many cases of appendicitis have been found to contain lead shot inside the lumen of the appendix; usually two, three, or four pieces are discovered. The following case is unusual because of the large number of shot found.

CASE REPORT

The patient, an unmarried woman aged 52, had a three-months history of vague abdominal symptoms which were becoming progressively worse. These symptoms consisted of pain in the epigastrium and in the right lower quadrant of the abdomen, flatulence, attacks of nausea, and, very occasionally, vomiting. The pain was in no way related to meals. There was no loss of weight and there had been no previous similar history. Associated with the abdominal symptoms was a history of occipital headaches and pains in the neck and shoulders for about the same length of time.

Radiological appearance

Appendix after removal

Clinical examination revealed a well-built patient with a marked absence of signs except for tenderness in the epigastrium and right iliac fossa, in neither of which was it very severe. In view of her age and the vagueness of the symptoms and signs a cholecystographic and barium meal examination was made.

The radiological report (Dr. S. Cochrane Shanks) stated: "The cholecystogram was normal, the stomach and duodenum showed a coarse mucosal pattern consistent with a gastro-duodenitis, but there was no sign of actual ulceration. The appendix was very long, and was filled in its distal half with what appeared to be lead shot. There was tenderness over the appendicular shadow. Doubtless the length of the appendix had something to do with the stasis in the distal half."

The case was referred to a consulting surgeon, Mr. Michael J. Smyth, F.R.C.S., who performed a laparotomy, with a paramedian incision extending from the umbilicus downwards. No abnormality was found except that the appendix was distended and bulbous, and was removed. The patient made a rapid and uneventful recovery, all her symptoms, including the head and neck pains, having disappeared.

A pathological examination of the appendix was made by Dr. E. Cuthbert Dukes, who reported as follows: "The appendix was enlarged and its wall was thickened. Its interior was packed with more than 60 small lead shots. No other abnormality was seen. Microscopical examination showed only a slight increase in fibrous tissue in the submucosa. In all other respects the histology was normal." (See photograph.)

It was later discovered that the patient often ate game, her brother being a first-class shot.

SIGHT AND SNAKES

Visual Development. By J. H. Prince, F.R.M.S., F.B.O.A. Volume I. Foreword by Professor H. Hartridge, F.R.S. (Pp. 418; 182 illustrations. £2 10s.) Edinburgh: E. and S. Livingstone. 1949.

Sight, Light and Efficiency. By H. C. Weston, F.I.E.S. (Pp. 318; 132 illustrations. £2 2s.) London: H. K. Lewis and Co. 1949.

Mr. J. H. Prince has travelled fifty thousand miles around and about the Antipodes collecting and examining animals of all types and descriptions, observing them in their natural habitats, watching what they do and do not do, looking into their eyes during life and sectioning them after death, seeking out naturalists, scientists, and just ordinary plain folk—anyone, in fact, who had information to impart. He has examined, watched, and listened to some purpose, and, what is still more important, his observations and deductions make fascinating reading.

With a verve which I hope will take him another fifty thousand miles he tells us in a few pages all there is to know about the development of vision and colour vision, visual imagery, and visual perceptions—the whole story of the evolution of the visual sense from its inception in light-sensitive cells to its fullest development in birds and the higher mammals. He tells how 3,000,000,000 years ago organic solutions reacted to light, 1,000,000,000 years ago unicellular organisms did likewise, 1,200,000,000 years ago amoebae developed primitive eye-spots, 550,000,000 years ago light recognition appeared, and 150,000,000 years ago cephalopods ultimately developed useful eyes; how dark-adaptation followed a flight for safety from predatory enemies to the abyss of the ocean, how the perception of the third dimension arose from the need to pierce the camouflage adopted by animals of shading into their environment, and the colour sense from the development of camouflage by colour. All kinds of knowledge is gained by the way, from how best to use a microscope and take photographs, through a mine of information (most of which I did not know before) on the shape of the pupil in hundreds of species and the appearance of the fundus—illustrated by beautiful paintings—of almost as many, to a discussion of the best way to restrain a snake or a lion when you examine its eyes.

There is plenty of excitement, too—for instance, an illustration of the danger of getting anaesthetized first if you give an anaesthetic to a buffalo to examine its fundus. The greatest thrill is the tiger-snake. Prince guillotined it so that he could look at its fundus without anxiety, but when he approached the severed head the jaws opened—apparently it still could see. The headless body disappeared out of the room, moving along with its severed neck raised until it was swallowed by another snake, and even then the headless snake struggled until the last inch of its tail had disappeared into the other's mouth.

Some of the theories advanced with such care-free assurance are to be viewed with caution (as that rods are developed from cones or that red and blue-green were the first colours to be appreciated), but Mr. Prince is a born observer, and observations—many of them original—are here in plenty. It is to be hoped he will soon set out on his travels again and let us have the pleasure of reading the second volume which he promises.

Sight, Light and Efficiency reminds us that the many problems of lighting, visual efficiency, and the care of the eyes at work are of interest to a wide circle. They concern not only the oculist, the industrial medical officer, the illuminating engineer, and the personnel representatives on industrial staffs, but also the industrialist or works manager, the foreman, and the worker, whose interests lie in the efficiency, safety, and comfort of industrial plants or offices. These problems have been somewhat neglected by British industry as a whole, and there is no doubt that if there were a wider realization of the benefits which almost invariably accrue from scientific illumination and adequate visual hygiene the dividends paid in increased production and improved morale at work-places would surprise most people who have not made a special study of these matters

It is no easy task to present the results of the great amount of technical research which has been directed to these problems, largely in this country and America, so that they are comprehensible to a varied and wide audience, the most important part of which is non-technical. In this Mr. Weston, whose original contributions to the subject are well known, has succeeded to a surprising degree. Nowhere else in this country will the case for visual efficiency and safety be found so well and authoritatively advanced The sense is admirably conveyed throughout by profuse illustrations and diagrams, many of which reveal more than usual originality. It is to be hoped that the book will enjoy a wide distribution, for it cannot fail to exercise an influence for good in a field which is too frequently neglected, and at a time when industrial efficiency and the maintenance of a high morale is of paramount importance in the national interest

STEWART DUKE-ELDER

A REVIEW OF HAEMOLYSIS

Hemolysis and Related Phenomena. By Eric Ponder. (Pp. 398; 69 illustrations. $6.00 or £2 10s.) New York: Grune and Stratton. London: J. and A. Churchill. 1948.

Here is a monograph of outstanding interest, particularly to the haematologist and the bio-physicist. No one is more competent than its author to present a critical review of the subject. He has made an authoritative and thought-provoking contribution to the complex and baffling series of problems of haemolytic phenomena in relation to the mammalian red cell. Dr. Ponder says that he has not set out to provide a compendium or source-book on the subject, but rather to act as a guide to those interested in the fundamentals of haemolytic phenomena.

In the first two chapters he considers shape changes in the red cell, with or without alterations in its volume. There is a full discussion of mammalian red cells, the disk-sphere transformation, various obscure phenomena, and atypical forms of mammalian red cells. Then follows a discussion on the measurement of red-cell volume, the principles and practical details of the different methods used, the effects of hypotonic media with their osmotic discrepancies, metastable states of the mammalian red cell, fragility measurements, and the factors influencing the rate of volume change.

Chapter four describes the cytochemistry and architecture of the red cell, including a consideration of the reversible sickling phenomenon and its bearing on the problem of red-cell structure, changes in the physical and chemical properties in disease, and cell inclusions.

In connexion with the kinetics of haemolysis, the author discusses the formal kinetics, with percentage haemolysis curves, and the technical procedure and analyses of these curves. This is followed by a consideration of the events leading up to, accompanying, and following haemolysis,

prolytic ion exchanges, prolytic volume changes, and the spot-wise action of lysins. An interpretation is given of evidence derived from various measurements—for example, fading time, impedance of haemolysed cells, and electrophoresis. The measurement of inhibition and acceleration of haemolysis (chapter six) under different influences and conditions indicates some of the properties of complex haemolytic systems. The final chapter is concerned with haemolysis *in vivo*, in which many problems are posed for elucidation.

This monograph will not appeal to many readers, but it is an essential addition to the library of the serious worker in this subject. The book is full of information and most valuable critical discussions of techniques, old and new theories, and mathematical, biochemical, and biophysical considerations of the haemolytic phenomenon.

JOHN F. WILKINSON.

VARICOSE VEINS

Varicose Veins. By R. Rowden Foote. (Pp. 226; 205 illustrations and 3 coloured plates. £1 12s. 6d.) London: Butterworth and Co. 1949.

The author has discussed adequately a very difficult subject, and a study of this book will well repay the time spent. The advice given on this ever-controversial topic is sound and orthodox, and the steps of treatment are lucidly described. The author, in my own opinion, belongs to the correct school, in that he endeavours to achieve a good thrombosis of the entire system of varicosities by a combination of ligation and thorough injection.

It is hard to confine the discussion to varicose veins alone, and the author has dealt with deep thrombosis of the leg veins in addition. In this section enough weight has possibly not been given to the value of femoral vein ligation, both during the active phase and later when complications are appearing in the lower leg. Certainly the dismissal of Leriche's method of lumbar ganglionic injection would not be shared by those who have witnessed the dramatic response to this simple measure.

The book is adequately illustrated, but some of the photographs are poor and could be improved and wrongly placed incisions marked plainly on the legs. Mistakes are few—equin(c)us (p. 186); and Leahy's swabs (p. 94), though small things, are Lahey's own. In the excellent photograph of an arterio-venous aneurysm (p. 49) the increased length of the leg is not commented upon. The historical chapter is excellent, but one looks in vain for the eccentric Baynton who did so much for varicose ulceration.

A. DICKSON WRIGHT.

British doctors have a characteristic fondness for old hospitals, old prescriptions, old signs, and old jokes, and the fifth edition of *Round the Fountain* (pp. 243; 4s.; London: St. Bartholomew's Hospital Journal, 1949) should satisfy all four weaknesses. It is a collection of excerpts from the *St. Bartholomew's Hospital Journal* from 1893 to this year. Some of the material has been published in previous editions, and the best of the last 22 years has been added. Bart's seems to produce poets rather than prose-writers, which is unfortunate, as the general standard of the articles is superior to that of the verse. A few passages have the laboured construction of old pieces from *Punch*, but most of the book reads freshly and entertainingly. It is also something of a social-history book, occasionally throwing light on the spacious and more leisured days earlier in the century—for instance, in a serious discussion by a houseman on dressers there is reference to those who "could not . . . be deterred from taking off their hats to me in the Square . . . and who would invite me to dine at their clubs." All students should read "The Keen Man," and every newly qualified resident would profit from the paper on "Housemaniasis." The book is not sufficiently parochial to exclude graduates of other hospitals from its enjoyment; Bart's men, of course, will skip through all the pages with delight.

BOOKS RECEIVED

Review is not precluded by notice here of books recently received

LONDON

SATURDAY DECEMBER 24 1949

SENSE AND INSTABILITY

In the opening pages of this week's *Journal*, published the day before Christmas, Dr. Russell Brain takes us away from the chief preoccupation of the medical man and a medical journal. No mean poet himself, he follows in the line of many learned physicians of the past in his interest in literature. In the brief "case histories" he records so well he illustrates his chosen theme of mental instability and literary genius. The world would seem to be reasonably well supplied with neurotics and psychopaths. Some of them have a brief burst of publicity in the columns of the sensational press; most of them suffer in obscurity and perplex only their relations and their doctors. But when a genius such as William Blake says he has spoken with Elijah in the field, the question is quickly asked whether this unusual manifestation is causally linked to his creative ability. The question has been asked about Darwin, and about Newton, whose eccentricities lapsed into near-madness when he accused John Locke of seeking to embroil him with women. Whether in science, in painting, in music, or in literature, one has not to look far for examples of what we commonly call abnormal behaviour.

Dr. Brain's list of psychopathic authors is at first sight formidable, and all the more so because it supports the popular impression that genius in writers is a near neighbour to madness, or even an inseparable companion. We are wary of having our preconceptions confirmed only by a list of cases that support them, but Dr. Brain cautiously concludes that "more than one process which the psychiatrist calls pathological may be an essential element in the virtues of genius—and perhaps of the rest of us." On the other hand, many great writers could be cited who never seem to have crossed the forbidden frontier. Yet we are left uneasily asking, How many? Since the limits of both genius and mental instability can be defined only arbitrarily, the question is likely to be left unanswered, and Dr. Brain poses it in another form: "Is normality more than a statistical myth?"

The common man, whose century this is supposed to be, would probably answer yes, for the idea of normality is certainly a popular myth and one of fairly recent evolution. It has been nurtured by the work of administrators and scientists, men who must abstract from a mass of data some general principle that can guide their actions when they set to work on the people or materials concerned. Since science and administration have come to penetrate every cranny of the citizen's life, their abstractions have crept into his mind and reappeared as beliefs. The arithmetical mean shines forth as normality. Common sense allows the normal to vary within limits on either side of the average, but for human conducts sets limits that alter in accordance with social circumstances. The limits of normality, like the average, are a myth founded on an arithmetical abstraction—the standard deviation.

Yet it must be admitted that, even if mental normality is a "statistical myth," writers themselves, in the words of Harold Nicolson,[1] "are largely to blame if the general public regard them as unbalanced." Citing Plato, Burton, Shakespeare, Dryden, Macaulay, and Lamartine as authorities for this "distressing theory," he pleaded that it is more a legend than a true account of the facts. Burton put his own opinion beyond doubt in the words, "All poets are mad"; and Baudelaire confirmed it when he recorded in his notebook, "J'ai cultivé mon hystérie avec jouissance et terreur." Since both these writers were at times mentally deranged, it is doubtful how general among men of genius their experiences were. We might cite in defence the work of Terman and his colleagues[2] in California. Since 1922 they have followed the development of a group of people with great intellectual gifts, and found that the mortality and insanity rates of the group are lower than those for the corresponding age groups in the general population. The divorce rate is also lower, and the delinquency rate is very low. But though men of genius are usually highly intelligent the converse is obviously not true, and the Californian group do not display genius as the word is used here. We cannot infer that, because the men discussed by Russell Brain reveal some gifts greater in degree than the selected Californians, they are a comparable group and should therefore have lower rates of insanity and so on. For their work enshrines an extraordinary creativeness that must be accompanied by gifts not found in men who are merely highly intelligent.

Dr. Brain concludes that there is a quantitative factor worth considering, and we may admit that, without designating them insane, most writers of genius have a greater range of variation in their personality than the common reader. More daring than most in their exploration of the richness of humanity, they have felt more keenly its glory and its guilt. The anxieties that afflict us all rock tempestuously these most sensitive, perceptive, and intelligent of men. Wilfred Trotter's observation that there can be no approach to truth without a threat to one's personality goes far to explain why

[1] *British Medical Journal*, 1947, 2, 782.
[2] *Psychological Approaches to the Biography of Genius*, Eugenics Society, 1947.

many writers have found a close alliance between genius and madness. Threat to personality was felt acutely by that abnormal man and many-sided genius Leonardo da Vinci, who wrote that to create he must be solitary: "While you are alone you are entirely your own, and if you have one companion you are half your own." It is hard, even for the man of genius, to remain out of the herd and at the same time show signs and symptoms of behaviour that the herd dubs normal. This anarchic tendency of his mind may progress so far that, like van Gogh, he may eventually find himself in an asylum in the company of other solitaries who, apart from their similarity to him in madness, differ completely in the commonplace nature of their achievements. It would seem that literary and artistic genius flourish in a society that is stable and prosperous, and wilt in a society that is unstable—another theme, perhaps, for Dr. Russell Brain to explore for our entertainment and delight.

A RITUAL OPERATION

Little is known of the origin of circumcision, despite the very considerable literature on the subject.[1] At its inception the practice seems to have had an essentially religious connotation and to have arisen independently in the continents of Africa, America, and Australia. Among the Semitic races it is probable that circumcision started as an act of consecration to the goddess of fertility with the object of winning her favour and thus ensuring the birth of children. Circumcision in ancient Egypt was certainly not undertaken for hygienic reasons, and probably it served as a sanctification of the reproductive faculties and a ceremonial initiation. It is likely that the ancient Pharaohs were circumcised, the circumcised state being a necessary qualification for the priesthood. It is reported that Pythagoras had himself circumcised while in Egypt so that he might be fully initiated into the esoteric religious rites of the Egyptians. Among others, notably the American Indians, circumcision was mainly adopted as an alternative to human sacrifice. Although circumcision is widespread in Moslem communities the Koran contains no specific ordinance on this subject. Mohammed is said to have been born without a prepuce, and the possession of a foreskin was regarded as a disgrace amongst the Arabs. It is reported that after one of the Prophet's battles a slain Thaqafite tribesman was found uncircumcised, and great pains were taken to prove that he was a Christian and not truly a member of the tribe. In Arab communities the operation is performed with scissors, a razor, or a split reed, and there is a tradition that Abraham used an axe and was rebuked for his haste.

Some of the methods of disposal of the foreskin are more a matter for interest than emulation. The Levites during the Exodus piled their foreskins in the wilderness and covered them with earth; in parts of West Africa, where the operation is performed at about 8 years of age, the prepuce is dipped in brandy and eaten by the patient; in other districts the operator is enjoined to consume the fruits of his handiwork, and yet a further practice, in Madagascar, is to wrap the operation specimen in a banana leaf and feed it to a calf. In happy contrast to some of these macabre practices is the habit of the Bani Chams in Australia, who merely perform a mock ceremony with a wooden knife and leave their victims unscathed.

In Britain, while the practice of circumcision is widespread, there are rather different reasons for its performance, and, though exact figures are difficult to obtain, it would seem that more than half the male members of the population are circumcised. Many doctors have for long rebelled against the wholesale and somewhat primitive lopping of the infant foreskin which goes on in some out-patient departments and surgeries. On these occasions the technique of the operation is frequently deplorable; sacrifice of skin is often too generous, and attendant damage to the glans penis or fraenum is not unknown. If these criticisms are valid then it may well be asked why large numbers of doctors permit and encourage a practice which so savours of the barbaric. Religious considerations apart, it is not easy to find a rational argument for circumcision in most cases, and the operation is more often performed because it is *de rigueur* in certain districts or a habit in some families.

Dr. Douglas Gairdner's valuable study, "The Fate of the Foreskin," which appears at page 1433 in this issue, will, we believe, make many readers pause for reflection. Though medical opinion about circumcision may be more conservative than it used to be, yet even to-day the attitude of the profession in general to the subject is too often based upon false ideas of the anatomy and physiology of what is a useful cutaneous appendage. Of the value of the prepuce in the first two or three years of life there is no doubt, for it has an important function in covering and protecting the glans penis. Contrary to widespread belief, non-retractability, a frequent finding, is not synonymous with phimosis. There can be little medical justification for routine circumcision of the infant, and the operation is only occasionally necessary under the age of 3. After this age operation is indicated for cases of non-retractability with true phimosis and for those with recurrent preputial inflammation or paraphimosis. Circumcision should be limited in extent: the fraenal region must not be damaged, and sufficient skin must be left to cover the very sensitive corona glandis. Although the operation of dorsal slit is unpopular with

some, it is both satisfactory and simple to perform, and the ultimate cosmetic result is good.

Apart from the local reasons for circumcision it is argued by some that it will reduce the incidence of venereal disease, cancer of the penis, and cancer of the cervix uteri. The evidence supporting the first of these contentions is inconclusive; the second is established beyond doubt; while the available data on cancer of the cervix do not warrant the conclusions which have been drawn by some authorities. As Dr. Gairdner points out, it is likely that lack of cleanliness is more important than lack of circumcision in the case of venereal diseases and cancer of the penis. If the latter was not a very uncommon disease in this country it alone might provide justification for widespread emulation of the Jewish custom. The Mosaic law enjoins the practice of circumcision on the eighth day, and it appears certain that this ritual circumcision affords complete protection against carcinoma of the penis. Furthermore it has been shown that circumcision between the third and fourteenth years of life does not give complete protection against penile carcinoma.[2] In the absence of more convincing evidence about carcinoma of the cervix it is difficult to ascribe its low incidence in Jewesses to the circumcision of their spouses. As Kennaway[3] has pointed out, the data are inadequate, and the low incidence in certain other races cannot be explained by the practice of circumcision. It seems safe to say that if Dr. Gairdner's recommendations are accepted much circumcisional morbidity and mortality will be avoided and, further, that there is no good reason to fear increased incidence of venereal disease or genital cancer as a result of this policy.

RADIOLOGY IN OBSTETRICS

The technical difficulties of obstetric radiography have prevented it from being so generally accepted as radiography in such other fields as the diagnosis of fractures or of diseases of the chest. At this year's Annual Meeting of the British Medical Association in Harrogate there was an interesting discussion in the Section of Obstetrics and Gynaecology on radiology in obstetrics, and two of the papers contributed to that discussion appear in the present issue of the *Journal*.

Professor J. Chassar Moir, describing the use of radiographs for assessing disproportion, begins with a plea for closer co-operation between the radiologist and the obstetrician. He himself has set the excellent example of being his own radiologist, but this happy combination is a rare one, since few obstetricians have the aptitude, training, or indeed the time to master the difficult and exacting technique of pelvic radiography. Professor Moir is the first to recognize the limitations of the method. It can give no more than a mechanistic picture of cephalo-pelvic disproportion, and it cannot measure such other factors as the efficiency of the uterine muscle or the mouldability of the foetal head. Nevertheless, mechanical difficulty remains the commonest cause of dystocia, and in skilled hands the radiographic method of measuring both the maternal pelvis and the foetal skull can achieve an accuracy far superior to anything that can be achieved by clinical means. There are probably two reasons why this method has not received universal acceptance as an essential part of obstetrical diagnosis—first because inaccurate measurement is all too easy in the absence of adequate skill and experience, and secondly because equipment for this type of radiography has not yet been used sufficiently widely for the method to have became a routine diagnostic procedure. Professor Moir makes the point that pelvic shape is at least as important as pelvic size, and the traditional measurement of the true conjugate may be of little value unless the other diameters of the pelvis are taken into account. Here radiography is of the greatest value, since it is the only means by which an accurate measurement can be obtained of the transverse diameter of the pelvic brim or by which a true picture of the shape of the pelvis can be obtained in the living subject. Pelvic size and shape, however, must be considered in relation to the measurement of the foetal skull in assessing disproportion. Most of the recent work on pelvic radiography has been concerned with these two factors, and many ingenious methods of relating them have been described. Professor Moir has devised three charts—for the brim, cavity, and outlet—from which an impression can be gained about the level at which difficulty may be expected with different sizes of foetal head. By this means he has succeeded not only in predicting difficulty in labour but also in indicating the cases in which an easy and rapid labour can be confidently expected. Obstetric radiography has tended to diminish rather than to increase the use of caesarean section, since in many cases where clinical examination appeared to reveal disproportion radiography has shown that, even when the pelvis was contracted, vaginal delivery was possible because the baby was small.

Measurement of the maternal pelvis can, on the whole, be made with more accuracy than measurement of the foetal skull. Dr. S. Josephs, in the second paper on this subject, discusses the intrauterine measurement of the foetal biparietal diameter. The accuracy of these measurements was checked after delivery of the child by independent observers who had no knowledge of the previous readings. Dr. Josephs does not give details of the actual method employed, but the results are impressive. The radiological method tended to overestimate the size of the head by 0.02 in. (0.5 mm.), but in the whole series it was found possible to predict the size of the biparietal

diameter to within 0.1 in. (2.5 mm.) in 75% of cases and to within 0.15 in. (3.75 mm.) in 95% of cases. One remarkable result of this investigation was that no growth of the biparietal diameter of the foetal skull could be detected between 36 weeks and 40 weeks. If this is confirmed it overthrows an opinion which has been generally accepted since the work of Scammon and Calkins[1] in 1929 indicated that the biparietal diameter of the foetal skull increases in size at the rate of 0.1 in. per week during the last four weeks of pregnancy. If it is true that the diameter of the foetal skull does not increase during the last four weeks of pregnancy—and confirmation of this observation is a matter of great importance—then it should be possible by radiological examination to predict the probable course of labour at any time from the thirty-sixth week to term. Study of the growth curve between 30 and 36 weeks also becomes of greater importance; simple clinical observation shows that the child's head must grow at some time between the thirtieth and fortieth weeks.

Though pelvic radiography must be regarded as still in an early stage of development, equipment for radiographic cephalo-pelvimetry should be provided in every maternity unit. The closest possible co-operation between the radiologist and the obstetrician is essential —ideally each case should be discussed as a diagnostic problem, and the results should be available to both. Great accuracy in measurement is also necessary, and it should be possible for radiographs to be taken during the course of labour. Radiographic pelvimetry is chiefly of value in doubtful cases of cephalo-pelvic disproportion, but the clinical features of the case require careful consideration, since radiology can do no more than exclude one important cause of dystocia. It would be wise, however, to carry out pelvimetry in every case where caesarean section is contemplated for disproportion, except perhaps in the case of obvious gross pelvic contraction, now rarely seen in this country. By this means some patients may be selected for trial labour and accomplish vaginal delivery who would otherwise have been subjected to elective caesarean section. One of the results of radiographic measurement of the pelvis has been the overthrow of many of the traditional ideas of the normal measurements of the pelvis. Since the time of William Smellie it has been assumed that the true conjugate should normally measure 4¼ in. (10.6 cm.), but recent radiographic studies have shown that the normal measurement is 4½ to 4¾ in. (11.3 to 12 cm.). Further, it is now doubtful whether the conventional external measurements of the pelvis, the interspinous, intercristal, and external conjugate diameters, have any practical clinical value. In fact they may often prove misleading, since a normal pelvis often exists with small external measurements, while the pelvis may be contracted though the external measurements are normal. Another important fact disclosed by radiographic pelvimetry is that dystocia may arise from contraction in any plane of the pelvis and not only, as was formerly assumed, at the brim or the outlet. It has also greatly increased understanding of the problems raised by outlet contraction. It appears certain that further technical advances will be made and that radiography for the detection of cephalo-pelvic disproportion will become as commonplace to the obstetrician as, for example, radiography of the lungs is to the chest physician.

INHIBITION OF AN ENZYME

Man's internal environment, his essential saline heritage, is preserved mainly by his kidneys. It is a strange evolutionary paradox that this internal environment, to be preserved within its needful narrow limits, must be constantly externalized as a copious protein-free glomerular filtrate, most of which is reabsorbed as it flows over the great and discriminating surface of the renal tubular epithelium. The excretion and selective reabsorption of this internal environment is one of the major circulations of the body. Homer Smith,[1] illustrating its magnitude, states that each day the energy of the heart and blood pressure pumps out as glomerular filtrate 170 litres of fluid, containing nearly half a pound (227 g.) of glucose and over three pounds (1.36 kg.) of sodium chloride, on to the surface of the renal tubular epithelium. As Smith writes, "Thus heart and kidney are literally pitched in constant battle against each other—our lives depend on neither one of them ever winning out." The wards of a general hospital are a reminder that the battle is ceaseless and that man is indeed delicately poised between dropsy and desiccation.

Among the achievements of the renal tubular epithelium in this circulation is its ability to excrete the excess acid of man's usual diet without a corresponding depletion of his stores of body base. R. F. Pitts,[2] reviewing concepts of this mechanism, strongly supports Homer Smith's view that this is accomplished by an exchange between distal tubular cells and distal filtrate of positive hydrogen ions for positive sodium ions. The tubular cells, rich in the enzyme carbonic anhydrase, excrete the positive hydrogen ions from carbonic acid, which is obtained from the dissolved carbon dioxide of the capillary blood and as a product of renal cellular metabolism. The positive hydrogen ions are exchanged for the positive sodium ions from the fixed base of the distal filtrate, the sodium ions being returned to the blood stream as sodium bicarbonate. The carbonic anhydrase in the distal tubular cells is an essential part of this mechanism, which serves the dual purpose of excreting acid and conserving sodium bicarbonate. Inhibition of carbonic anhydrase in this cycle might therefore be expected to diminish the reabsorption of sodium, forcing it out of the body, to promote acidosis by diminishing the

excretion of hydrogen ions, and thus to lessen the acidity of the urine.

This enzyme inhibition has been produced experimentally by giving sulphanilamide,[4] which by virtue of its free sulphonamide group is a specific inhibitor of carbonic anhydrase.[5] Schwartz[6] attempted to force a therapeutic loss of sodium from the body in congestive heart failure by the administration of sulphanilamide and obtained a limited success in three patients. His results supported the ionic exchange concept and were in accord with the predicted biochemical changes. He emphasizes, however, that the drug is too toxic for further trials and he hopes to find a less toxic compound containing a similarly effective free sulphonamide group. It is possible that a similar enzyme inhibition may be the fundamental biochemical lesion in some clinical cases of acidosis. Stapleton[7] recently reported a case of idiopathic renal acidosis in a child with severe dehydration, chronic malaise, and vomiting. The urine, however, remained alkaline and contained sodium bicarbonate despite an abnormally low plasma bicarbonate. The biochemical pattern and the child's health were restored when she was sustained by protracted administration of alkali. Stapleton suggests that in this form of acidosis the biochemical lesion may be an inhibition of carbonic anhydrase. These experimental, therapeutic, and morbid variations all illustrate a vital part of the external circuit of man's internal environment, a circuit in which 400 g. of sodium bicarbonate are tentatively excreted each day, roughly five times the total body store of available base.[4]

MEDICAL DICTIONARIES

So detailed has the study of medicine become that the student taking his final examinations must already have mastered the equivalent of a foreign language if he is to make his terminology understandable to the examiners. Though most medical terms are of Latin or Greek origin, many students now have little Latin and less Greek. When he goes on to do some research or extend his interests the student finds that a knowledge of French and German is desirable, and many of the examinations for higher qualifications require him to translate a piece from one of those languages. Though there are a number of helpful dictionaries for the more commonly used languages it is questionable whether they are adequate for the research student's requirements, and, now that more countries where Slavonic languages are spoken are producing books and journals that should be read, the need is increasing for dictionaries giving an up-to-date translation into English of medical terms from the Russian, Bulgarian, Serbo-Croat, and the others. Discussing the journals in foreign languages read in libraries, Dr. Raymond Whitehead[1] said recently: "The insignificant representation of other foreign languages [than French and German] probably means that few if any users of the library read them; it does not mean that the medical literature in these languages is unimportant—evidence to the contrary is provided by a steady demand for translations from them by those using the library."

A report on technical dictionaries prepared for Unesco by J. E. Holmstrom[2] shows that, though there are three medical dictionaries into Russian, there are apparently none from that language into English, nor are there any from Portuguese into English or from English into Portuguese Two good modern medical dictionaries connecting English with French both ways are said to be in the press. As Mr. Holmstrom points out: "Adequate provision of medical dictionaries is to be regarded as a matter of indirect but urgent humanitarian importance, equally for languages in which original research is published and for those of medically backward countries such as China." The need of these medically backward countries is now great, for many are developing the technical resources that will enable them to make use of research carried out in countries at present more advanced technically. In a rather different category are India and Pakistan. As their link with Britain becomes less intimate than formerly, presumably fewer of their medical men will be able to read and write English with facility, and adequate medical dictionaries will be needed for them if they are to keep in touch with the scientific advances of the English-speaking world. There is no necessity yet for a British-English–American-English medical dictionary, but Mr. Holmstrom shows that in some branches of technical terminology, notably in engineering, we and the Americans often give quite different names to the same thing. We can only hope that such divergence does not become common in medicine.

Mr. Holmstrom suggests that Unesco should gather further information and criticisms of the report, and then consider establishing an international terminological bureau under the joint auspices of Unesco and the International Organization for Standardization. The bureau might be located at Geneva, so that it could be in close touch with the latter organization, or it might be attached to the Science Museum Library in London, or to some other established bibliographical centre. The bureau would conduct research into technical terminology and dictionaries compile and publish standard terminological definitions and equivalents, and, when any definitions, equivalents, or sketches had been approved by the appropriate bodies, authorize them to be printed by commercial publishers accompanied by a suitable symbol indicating that they were approved by the bureau. He wisely considers that publishers should be at liberty to mix approved terms with any others, which would be unaccompanied by the symbol, for language depends on usage, which varies among writers.

The report includes an interesting speculation on whether an electronic machine might be constructed to produce translations. The possibilities are fascinating, though perhaps their realization is still rather remote. The machine translation might be full of "howlers," but an editor acquainted with the subject matter would be able to make it readable and accurate even though he did not know the language from which the work had been translated. Meanwhile the work of translating and abstracting from the world's medical literature is being carried out by more old-fashioned methods by *Abstracts of World Medicine* and *Abstracts of World Surgery*, which draw the attention of medical practitioners and students to the more important medical papers published all over the world and summarize the contents for them.

FIBROCYSTIC DISEASE OF THE PANCREAS

The publication in 1938 of Dorothy Anderson's[1] series of 49 cases of fibrocystic disease of the pancreas led to recognition of the disease as a clinical entity. She divided the cases into three groups: neonatal, infantile, and childhood. Fourteen cases recently reported by Pitt[2] in Australia all belonged to the third group. In a paper which appeared in this *Journal* some weeks ago Matheson[3] described seven cases seen in one hospital between June, 1947, and September, 1948—this amounted to 2% of the medical admissions to the children's ward during that period. The evidence suggests that the disease is inherited,[4] and Matheson considers that the inheritance may be explained by incomplete dominance.

The signs of the disease are malnutrition, the frequent passage of large, offensive, pale stools, and cough, which may resemble whooping-cough. Clubbing of the fingers is usual. The appetite is good—a feature which distinguishes this condition from coeliac disease. Inadequate pancreatic secretion appears to cause a fatty liver and eventually cirrhosis, a process analogous to that which occurs in dogs after removal of the pancreas. The diagnosis is not always easy, but the presence of fatty stools with a high nitrogen content and signs of vitamin-A deficiency in a child without evidence of a tuberculous infection in the chest or abdomen are indicative. The fat content of the stools may be misleading, for although the amount is very high a large proportion may be found as split fat, owing to the effect of intestinal lipase and bacterial action. The older the stool when it is examined the higher the percentage of split fat will be.

Fibrocystic disease of the pancreas can be distinguished from coeliac disease by examination of duodenal contents, but the collection of duodenal juice from a child may not be a harmless procedure. The vitamin-A absorption curve is always subnormal, but this does not help to distinguish the condition from coeliac disease and other intestinal disorders. Recently attempts have been made to investigate protein metabolism by amino-acid curves; whereas there is a definite rise and fall over three hours in normal children and those with coeliac disease, the curve hardly departs from the fasting level in cases of fibrocystic disease of the pancreas. Radiographs of the lungs are said to show a stage of collapse associated with obstruction of the bronchi, and, later, great accentuation of the hilar shadows. Shadows in the lung fields characteristic of peribronchial infiltration have also been described.[5] It must be remembered, however, that respiratory infection often occurs in coeliac disease, and it would be hard to support a claim that the *x*-ray appearances of the lungs in fibrocystic disease are pathognomonic. Indeed, there is no single feature, with the exception of the alteration in the protein metabolism, which can be taken as a definite distinguishing sign between cystic disease of the pancreas and coeliac disease, though the respiratory disturbances are more severe in the former than in the latter. Therefore, when a case of steatorrhoea occurs in a child, the possibility of cystic disease of the pancreas should always be considered. The usual treatment is to give a high-calorie protein diet, with added vitamin A, and pancreatin by mouth. Fats should be restricted. For respiratory infections penicillin will be required. Matheson suggests that the results of treatment might be more successful than those generally obtained at present if the mucus which collects in the bronchial tree could be liquefied.

HUMAN PLASMA PHOSPHOLIPID FORMATION

A phospholipaemia is a common finding in association with liver disease and many other conditions. In any of these the raised plasma phospholipid may result either from over-production or from diminished utilization in the tissues. Radioactive tracers can be used to determine which of these two mechanisms is responsible. Radioactive phosphorus is incorporated within a few hours into the plasma phospholipids.[1] Accumulation of the latter in the plasma due to inadequate utilization would be indicated by a relatively low level of radioactive phosphorus, since the newly formed phospholipids would be diluted by those already accumulated. On the other hand a lipaemia due to increased synthesis would be reflected in a higher level of the radioactive element. Balfour[2] applied these principles to the study of lipaemia in twenty patients with various types of disease, including obstructive jaundice, nephrotic nephritis, and portal cirrhosis. Nine normal subjects were used as controls. In all cases whatever the cause of the blood lipid change, a direct correlation was found between the level of phospholipid in the plasma and the quantity of newly formed phospholipid as judged by its specific radioactivity. Since the liver is the main and probably the only source of plasma phospholipids,[3] it may be concluded that in all Balfour's cases the hyperlipaemia resulted from over-production in the liver. Since, however, the same results were obtained in cases of advanced liver disease, the liver appears to possess great powers of synthesis. Experiments by Chaikoff and his colleagues,[4] however, indicate that there may be an alternative explanation of Balfour's results. Using radioactive phosphorus as a tracer they found in dogs that choline increased the turnover of the phospholipid in the liver, but not in the plasma. They therefore suggest that the reduction in liver fat which is a consequence of the administration of choline is not due to increased transport but to increased utilization within the liver itself. A rise in plasma phospholipids in hepatic disease might therefore be expected if their intrahepatic consumption was more impaired than their production. Since hepatic injury, particularly if severe, is more likely to be associated with depression than stimulation of liver function, it is more than probable that the apparent over-production of phospholipid results from impaired intrahepatic utilization.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE MANAGEMENT OF ACUTE DYSPEPSIA

WITH SPECIAL REFERENCE TO GASTRIC AND DUODENAL ULCER

BY

F. AVERY JONES, M.D., F.R.C.P.

Physician-in-charge, Gastro-enterological Unit, Central Middlesex Hospital; Consultant in Gastroenterology, Postgraduate Medical School of London

Dyspepsia is a common symptom for which there are many causes. Discomfort related to meals, epigastric fullness, flatulence, soreness, and heartburn may merely signify a disturbance of function of the stomach, often the result of some form of stress. This stress may be nervous or emotional, as from acute anxiety or sustained annoyance: or it may be physical, the result of over-fatigue, late nights, or insomnia; or it may be acting directly on the stomach from hurried meals, badly cooked food, or excessive drinking. Heavy smoking, habitual purgation, or continued use of aspirin may be having an irritant effect on gastro-intestinal function. A psychoneurosis is another possible reason for a functional dyspepsia.

These causes account for a high proportion of the dyspepsias. The next common cause is peptic ulcer, and again many of the above stress factors may have been present. Whether or not a given set of stimuli cause functional dyspepsia or produce an actual ulcer possibly depends on the time the adverse factors have been operating and on their intensity, both of which may also depend on the personality of the individual. The carefree fellow will meet his disappointments and frustrations with equanimity and quickly forget about them; the sensitive, worrying individual will magnify difficulties and bottle up his resentments, stimulating nervous impulses which pass down to his stomach and intestine. If he is also over-conscientious he will not stop working and rest like many of his fellow men. Sudden calamity in the life of a normal stable individual may be enough to fire the mechanism which produces the peptic ulcer, and acute symptoms may begin without any preceding indigestion.

Although this relation between stress and ulceration may often be found, there are many patients in whom the most careful inquiry will fail to reveal any untoward event preceding the onset of symptoms. Physical and mental stress are two aetiological factors, but there are probably others which are subtly associated with modern life and which have so far escaped recognition.

Differential Diagnosis

Other diagnoses have to be kept in mind, particularly for the milder degrees of indigestion. Carcinoma of the stomach is, numerically, an infrequent cause of indigestion, but must nevertheless be carefully excluded. Gall-bladder disease may produce a flatulent dyspepsia. Oesophageal hiatus hernia, or oesophageal ulcer may lead to acute discomfort, particularly when the patient lies down. Helminthic infestation is an occasional cause, and there are also diseases affecting other organs—e.g., cirrhosis hepatis, pulmonary tuberculosis, early heart failure, and incipient uraemia—which may produce dyspepsia.

Investigation

A careful history and examination are the first essentials, and may bring to light significant factors of probable aetiological importance. In the majority of cases a barium meal should be arranged, to increase the accuracy of the diagnosis. One is constantly being surprised to find gastric or duodenal ulcers in patients whose symptoms have been slight and atypical. However, it is not uncommon to receive a negative *x*-ray report on the patient with a convincing ulcer history. Examination of stools for occult blood is a valuable investigation, but a fractional test meal is of little diagnostic assistance. Gastroscopy is useful when there is a discrepancy between the clinical and radiological findings, and may clinch the diagnosis between a simple and a malignant gastric ulcer. In some difficult cases laparotomy is still the final arbiter.

Simple Stress Dyspepsia

This is mainly associated with anxiety states, and the symptoms lack the clear-cut periodicity of ulcer dyspepsia. Discomfort is common immediately after meals, and aerophagy is often present. The internal emotional tension may be well concealed at first, even though the individual may feel at the "end of his tether." A sympathetic hearing of the patient and a confident explanation of the mechanism of the symptoms, combined with adequate sedation and hypnotics, a holiday, and a review in four to six weeks, are the essentials of treatment. In particularly sensitive individuals initial rest in bed away from home may be desirable, and in other cases there may be some obvious physical stress which can be diminished.

Ulcer-like Dyspepsia with a Negative Barium Meal

There are patients who present with typical ulcer symptoms, yet the radiograph is reported as normal. These patients may have a history of recurring bouts of dyspepsia with gnawing epigastric pain related to meals, eased by food or alkaline powder, and possibly waking the patient at night. They should be regarded as having a peptic ulcer and treated just as energetically by rest in bed, antacids, sedatives, and a careful investigation of the personal aspects of their case. It is probable that many of these patients have subacute ulcers, as they tend to return later with undoubted evidence of peptic ulcer, or gastroscopy may reveal subacute (and occasionally chronic) lesions which have escaped radiological detection. At least three weeks' rest in bed should be advocated and the same treatment prescribed as for duodenal ulcer. In the past these cases have often received inadequate treatment, but if neglected at this stage irreversible changes may develop and a chronic ulcer supervene.

Duodenal Ulcer

The treatment of choice, especially for patients with a recent history, is initial rest in bed, preferably away from home; but that is often difficult to manage. Hospital accommodation in the country is totally inadequate to allow in-patient treatment of all but a minority of duodenal ulcer subjects.

Six weeks' rest in bed is desirable. Many patients will greatly prefer to continue at work, but this is to be resisted unless the rest in bed is clearly going to add to their anxieties. Rest in bed almost certainly favours the healing process, and it impresses the need for care much more

than if ambulatory treatment were undertaken. It provides opportunity for reflection and perhaps the adoption of a better perspective. The complete break will allow excessive commitments to be shed without loss of prestige. With rest in bed there must be adequate sedation during the day and adequate sleep at night, otherwise much of the benefit of the rest will be lost.

The radiological control of healing of duodenal ulcer is difficult and, indeed, impossible unless the ulcer crater is well seen initially.

Gastric Ulcer

The presence of a definite lesser-curve ulcer should always be regarded seriously. The characteristic niche, projecting cleanly from the middle of the lesser curve, is practically never a malignant ulcer; but an ulcer in the antrum, at the cardia, or well away from the lesser curve must be regarded with suspicion and investigated further.

Large gastric ulcers can heal even if the individual barely diets and stays at work, but it is extremely likely that without treatment the chance of the ulcer becoming chronic is greatly increased. Loss of pain is an entirely unreliable guide, for ulcers may remain present and symptomless for many months. The treatment of choice is rest in bed, preferably away from home, until healing takes place. This may be within three weeks, but it may need several months. Good convalescence should follow radiological healing of the ulcer, as gastroscopic studies have shown that the crater may still be present for several weeks after it has disappeared radiologically. Gastric ulcers are associated with a higher mortality than duodenal ulcers when they bleed or perforate, and there is the slight risk of malignancy. No compromise is possible, and if healing will not take place a partial gastrectomy must be advocated.

Dietetic Treatment

Treatment is based on the principle of giving two-hourly milk feeds and as pain subsides adding bland foods to maintain adequate protein, calorie, and vitamin requirements. The rate of increase must be decided in each case by the relief of pain. The diet should be attractive and colourful, as the irritation of a dull diet more than offsets the benefit from the loss of psychic stimulation of gastric secretion. The diets below are practical but not perfect, and more protein and fat in the form of eggs and cream would be of value.

The following dietary was given by Fletcher in 1948: reprints of his valuable pamphlet for patients can be obtained from *The Practitioner*. The patient should be told that the diet sheets should be regarded as a general guide, and that he must not get fussed or worried if occasionally he has difficulty in following them.

First Stage: Strict

Two-hourly milk feeds may be given, alternating with 5-oz. (140-ml.) feeds of egg and milk, or Benger's food, "ovaltine," "horlicks," malted milk, or junket. An example of stage 1 diet is given below.

8 a.m.—5 oz. of custard mixture
10 a.m.—5 oz. of milk
12 noon—5 oz. of custard mixture
2 p.m.—5 oz. of milk
4 p.m.—5 oz. of custard mixture
6 p.m.—5 oz. of milk
8 p.m.—5 oz. of custard mixture
10 p.m.—5 oz. of milk
(5 oz. = 140 ml.)

At night (if awake) 5 oz. of milk may be given.

All feeds should be taken warm (not hot), and plain water in small quantities may be allowed in addition. Between each feed (that is, at 9 and 11 a.m., and at 1, 3, 5, 7, and 9 p.m.) and at night, if awake, alkaline powder or medicine should be taken.

If there is vomiting the milk should be diluted half-and-half with water and only 3 oz. (85 ml.) taken at each feed.

If there is no vomiting and pain rapidly subsides the patient may be allowed two plain biscuits, or two small pieces of crisp toast buttered when cold. These are taken at 10 a.m., 2 p.m., and 10 p.m. with the 5 oz. of milk. If improvement continues the patient may be given a little strained porridge or patent cereal baby food at 8 a.m. and a small helping of pudding at 12 noon and 8 p.m. for two or three days before starting the stage 2 diet.

Extra nourishment can be obtained by adding a teaspoonful of sugar to each feed, and this should be done if the diet is taken for more than two days.

The milk feeds may be flavoured with a little cocoa or with "ovaltine," "bourn-vita," or "horlicks," or the milk may be taken in the form of junket.

Custard Mixture.—This should be prepared for the day by stirring two eggs (fresh or reconstituted dried) into 16 oz. (450 ml.) of milk. Before the mixture is served it should be thickened by warming and, if desired, flavoured with vanilla or chocolate. If one cannot get enough eggs to make the custard mixture, a proprietary brand of "strained custard pudding" may be used or better still a "fortified milk mixture" made by adding 2 oz. (55 g.) of dried milk powder or 1½ oz. (40 g.) of dried protein milk—i.e., "prosol" ("trufood")—to 1 pint (570 ml.) of milk.

Second Stage: Moderate

An example of a stage 2 diet, which is considerably fuller, is given here.

6 a.m.—5 oz. of warm milk.

8 a.m.—Small helping of patent groats, patent barley, or strained porridge made with milk to which "bemax" may be added; two slices of crisp toast, buttered when cold; one lightly boiled or poached egg, or scrambled dried egg; 5 oz. of milk flavoured with weak tea: jelly, honey, or syrup.

10 a.m.—5 oz. of warm milk.

12 noon.—Small helping of steamed fish or egg, as at 8 a.m.; two slices of crisp toast or plain biscuits with butter; small helping of pudding; 5 oz. of milk (including that used in pudding); add small helping of creamed potato after one week on stage 2 diet.

2 p.m.—5 oz. of warm milk or milk pudding (for example, junket, egg custard, or corn-flour).

4 p.m.—5 oz. of milk with weak tea; two slices of crisp toast or biscuits with butter; small slice of plain cake, jelly, syrup, or honey.

6 p.m.—5 oz. of warm milk or cream of vegetable soup.

8 p.m.—Same as at 12 noon.

10 p.m.—5 oz. of warm milk.

The times may be varied so long as the intervals between feeds are not longer than two and a half hours. Sugar or glucose may be taken as desired. If the patient is thirsty, water or fruit juice may be taken, but not more than 5 oz. at a time. The milk feeds may be flavoured with a little cocoa, "ovaltine," "bourn-vita," "horlicks," or very weak tea, or they may be taken in the form of junket.

For the prevention of sepsis in wounds and burns

PROPAMIDINE CREAM —M&B

PROPAMIDINE CREAM is recommended for both the prophylaxis and the treatment of infection in wounds and burns. Clinical experience has shown that, where penicillin is applied topically sensitization of the patient to penicillin may occur, and that its use sometimes leads to the development of resistant strains of organisms. Propamidine has the advantage over penicillin in that neither of these phenomena has been observed, and for this reason Propamidine is preferred by many doctors.

SUPPLIES
Propamidine Cream is supplied in 1 oz. tubes and 16 oz. jars

NEW STRENGTH 'ALBUCID' SOLUBLE

Eye Preparations

Now available

20% EYE DROPS 10% EYE OINTMENT

THE GENTLE GIANT

'Albucid' Soluble in Ocular Therapeutics

FOR TISSUE of the highest sensitivity it is essential that local chemotherapy be effected by agents free from irritation. 'Albucid' Soluble Eye Drops are adjusted to pH 7.4 and are thus free from irritating alkalinity. High therapeutic efficiency, combined with ready solubility and very low toxicity, makes 'Albucid' Soluble the agent of choice in most eye infections. 'Albucid' Soluble Eye Ointments, containing 'Albucid' Soluble in a neutral cream base, are available for the treatment of infections of the eye and lids, where a slower and more prolonged absorption may be considered advantageous.

LONDON, W.8

343/H

For the Relief of Pain in Migraine . . . .

"DIHYDROERGOTAMINE-SANDOZ"

"Dihydroergotamine-Sandoz" is effective in aborting the true migraine attack and in preventing the occurrence of excruciating pain. This is best obtained by early parenteral administration, which is efficacious in 90 per cent of cases. Oral administration is also beneficial in a lesser proportion of cases, particularly mild ones. "Dihydroergotamine-Sandoz" may be given where other ergot preparations are badly tolerated, and during the menses and pregnancy.

Full clinical information available upon request to:—

SANDOZ

SANDOZ PRODUCTS LIMITED

134 Wigmore Street, London W.1

SANDOZ

Ascorbic acid tablets (50 mg.), blackcurrant purée, or rose-hip syrup should be taken daily.

Third Stage: Convalescent

A sample diet for stage 3 is as follows.

Breakfast.—Cornflakes, patent groats or barley, or strained porridge with "bemax" and 5 oz. of milk; lightly boiled, poached, or scrambled egg (shell or dried); bread or toast and butter; weak, milky tea; honey, syrup, or jelly.

Dinner.—Boiled, steamed, baked, or grilled white fish, soft roes, tripe, brains, sweetbread, chicken, or rabbit. White sauce. Lamb, tender beef, or liver, minced if possible, may be allowed; mashed potato; soft parts of well-cooked root or green vegetables (sieved if possible) or cauliflower; pudding (see below); bread or toast and butter.

Tea.—Bread or toast and butter; plain cake, or biscuits; milky tea; honey, syrup, jelly, or pea-nut butter.

Supper.—Boiled or steamed fish, egg as at breakfast, or grated cheese; bread or toast and butter; sieved vegetables; milk (with weak coffee, tea, or cocoa) or milk vegetable soup.

(*Note.* The bread should not be new; the toast should be crisp and buttered when cold).

In addition to these four main meals, one of the following snacks should be taken in the intervals between them, before going to bed, and if awake at night, so that the patient never has more than two hours during the day without taking food.

Snacks.—Small cup of milk (flavoured with weak tea, very weak coffee, "ovaltine," "bourn-vita," cocoa, or "horlicks," if desired); or ½ oz. (15 g.) of plain or milk chocolate; or two or three tablets of "horlicks" malted milk or "ovaltine," or two plain biscuits or slices of crustless bread with butter and jam or paste, or a slice of plain cake.

Ascorbic acid and medicine should be taken as in stage 2 diet.

Suitable Puddings.—Suitable puddings may be made from junket, well-cooked rice, ground rice, corn-flour, semolina, tapioca, vermicelli, arrowroot; and flavoured with coffee, chocolate, caramel, almond, or vanilla. Milk jelly and all other kinds of jelly; custard, baked or boiled; blancmange; steamed sponge or castle puddings; fruit fool; sieved stewed apples, pears, prunes, plums; sweet omelet; queen of puddings; meringues, ice-cream, trifles, sieved apple charlotte.

Medication

The most important single drug in the management of peptic ulcer is phenobarbitone, given in sufficient doses to have the desired effect of sedation. The dose must be worked out individually for each case, starting with ½ gr. (32 mg.) three times a day. Sodium amytal is a valuable alternative, starting with ¼ gr. (48 mg.) t.d.s.

Antacids are of some value during the initial phase, and "aludrox" or "lactalumina" may be given, one dessertspoonful with water four to six times daily, half to one hour after meals. Other antacids recommended are magnesium trisilicate (30 gr.—2 g.) or equal parts of calcium and magnesium tribasic phosphate (30 gr. of each). Neither of these is as good as the soluble alkalis for the relief of pain, and during the initial phase the addition of sodium bicarbonate can be most useful—e.g., tab. alk. co. effervesc. may be given, or mist. magnesii trisilicatis composita (*N.F.*), which contains 10 gr. (0.65 g.) of magnesium trisilicate, light magnesium carbonate, and sodium bicarbonate.

Belladonna is probably of most value when taken at night, and may stop night pain. Tinct. belladonna. 15–30 min. (0.9–1.8 ml.) may be given, or the dry extract may be combined with phenobarbitone aa ½ gr.; the dose is one to two tablets. Olive oil (½–1 oz.=14–28 ml.) before meals is a useful adjunct, especially in cases of duodenal ulcer.

Special Measures

The underweight patient should be given extra protein "Bemax" (1 oz.=30 g.) is a useful supplement, as it contains 30% protein in addition to the vitamin B complex Fortified milk feeds at night are most useful—for example:

5 oz. (140 ml.) milk
½ oz. (14 ml.) half-cream dried milk
¼ oz. (20 mg.) "prosol"

Flavour as desired with cocoa, vanilla, or coffee. A milk drip is invaluable if there is severe pain at first, and a milk drip at night is a useful additional therapy for duodenal ulcer. Use a very thin Ryle's tube passed through the nose and give 2 pints (1.1 litres) of milk during the night or 6 pints (3.4 litres) in the 24 hours. Evaporated milk in the proportion of 15 oz. (425 ml.) to 25 oz. (700 ml.) of water may be used. This is more satisfactory than dried milk.

Surgery

There is no hard-and-fast line between medical and surgical treatment, and each case requires individual assessment. Under the age of 45 the chance of death is small, but surgery may be needed to save a man's job rather than his life. If crippling relapses incapacitate him he has earned a partial gastrectomy. Over 45 years there is increasing risk of death from complications if ulcers remain unhealed. If the general condition and the surgical facilities are good there should be no hesitation in operating on the patient who is unable to heal his ulcer or has recurrent complications. Partial gastrectomy is the operation of choice, and its mortality has declined considerably recently with increasing experience of surgeons and the introduction of new anaesthetic techniques and antibiotics. Nevertheless, there is a small mortality and morbidity which must still encourage the practitioner to administer medical treatment thoroughly before surgery is recommended.

Aftercare

The risk of subsequent relapses can be reduced by attention to certain aspects of the patient's life and habits. He must have a clear appreciation of the effect of emotional reactions in predisposing towards or causing further ulceration. Minor environmental difficulties may be more harmful than personal catastrophes. There must be a calm, philosophical outlook and a refusal to allow small troubles to accumulate into a pent-up load of resentment or frustration. If the patient finds himself becoming tense he must be encouraged to take phenobarbitone (½ gr. t.d.s.). The practitioner can assist greatly by encouraging regular consultations, at first every six weeks, then every three months, and finally three times a year. A sympathetic understanding of the difficulties and the advice of an independent observer may greatly help the individual.

The patient should avoid undue fatigue, chilling, and work which involves constant bending; but it is seldom advisable to change the patient's occupation, for this often causes more problems than are solved. Regular hours are highly desirable, and limitation of overtime duties is necessary.

Dietary restriction is probably of value indefinitely, but the most important aspect of feeding is maintaining regular meals without long intervals between them. The patient is well advised to avoid fried foods of all kinds, pastries and suet, pickles and spices, curry, pepper, onions, reheated dishes, coffee, strong tea, and anything which he finds indigestible. Priority milk should be continued, and has proved to be of great value for many patients with a ready tendency to relapse. Alcohol is best omitted for six months and then allowed in strict moderation. Smoking should be restricted, or preferably stopped, but it is legitimate to allow a few cigarettes after meals, unless the patient relapses.

Continued medication with antacids or atropine is not desirable, but the patient should have a supply of phenobarbitone. He should be strongly advised to rest completely at the onset of a relapse and return to the strict ulcer regime, for early treatment may abort an otherwise long and tiresome recurrence.

MEN AND MEDICINE*

BY

T. M. TAYLOR, C.B.E., K.C., M.A., LL.B.
Principal of Aberdeen University

You are entering on your profession at a time when great changes have taken place not only in the practice of medicine but also in the organizational forms under which it is conducted. It is far too soon to pass any verdict on the National Health Service, whether of praise or of blame, but one danger is already apparent—that its financial arrangements may easily tend to draw men away from general practice into so-called specialisms, with results that on the long view may be detrimental to the weal of the patient and the general progress of medicine.

It will be an ill day for the community when the general practitioner degenerates into a filler of forms or an automatic machine dispensing chemical panaceas. In earlier times the specialist usually graduated from the field of general medicine or surgery in which he was accustomed to deal with his patient as a human being set in a particular environment. Now the specialist at the very beginning of his career will be tempted to immure himself in his specialty, and the danger may be not only that the range of his own medical knowledge will be restricted but that he may come to lack understanding of the patient's environment and of the problems that face the general practitioner.

I am aware of the theoretical arguments in support of this trend. They start from the proposition that medicine is a science—i.e., an attempt to make knowledge quantitative—and in their extreme forms they suggest that the best results may be attained by subjecting the patient to the attentions of a series of specialists, each producing his quantitative report with a Grand Co-ordinator at the top who collates their reports and then prescribes the appropriate remedy. This picture, I will concede, is caricature, but it is not an unrecognizable distortion of some things that may be read or heard. The other theory rests on the contention that medicine is an art and that there is no difference in principle between the doctor making up his mind and the judge framing his judgment, the painter building up his picture, or the cook producing a good meal. In each case the practitioner of the art requires to take a total view of the situation, balancing the different elements with a delicate sense of relevancy. It is this intuitive sense of relevancy and balance that makes a judgment—legal, medical, aesthetic, or culinary—and in each case the art is learnt by doing the job and by following the practice of the acknowledged masters. It cannot be disputed that contemporary medicine owes much to the quantitative approach of exact science, but on the other hand it must not be forgotten that many of the great discoveries have come by chance to men who, like Saul, were looking for their father's asses and found a kingdom. Others again, as Sir James Mackenzie was never tired of saying, were due to general practitioners who were capable of using their own observation and clinical nous to some purpose.

Pastoral Medicine

If the practice of medicine is an art rather than a science it is equally true that the patient himself is not a mere natural object to which the techniques of physical science can be universally applied. I think it will be increasingly recognized that man has a spiritual structure which must be respected no less than the physical structure with which it has some kind of relation. It may be that the conditions of modern industrial society are themselves a violation of this essential structure, and that the increase of nervous tension and mental instability and the growing resentment of the industrial proletariat are symptoms of a violation too gross to be palliated by mere adjustments of social mechanism. However that may be, there now devolves upon the doctor in general practice a quasipastoral function which derives from the pathetic and indeed terrifying trust which simple folk repose in him. It is to be feared that the medical course, grossly overloaded as it is admitted to be, is a most inadequate propaedeutic for the discharge of a ministerial function of this kind. It becomes a question whether there should not be a course in pastoral medicine as well as in pastoral theology. Such a course would take the student into deeper waters than can be plumbed by operational techniques and the measuring instrument of the laboratory.

For the great scientific advances of our time have singularly little bearing on the decisions which have to be taken in men's daily lives and which, over a period of time, affect them profoundly for weal or woe. Scientific discovery can do much to change the environmental framework within which decisions have to be taken, but the decisions themselves depend on factors that derive from custom and tradition, from poetry and literature, from philosophy and religious belief. This fact, once you perceive and realize it, may well serve to keep you humble. But those are questions that you will have to face in the years that are to come.

*Part of a graduation address given at Aberdeen University, September, 1949.

The American Trudeau Society, medical section of the National Tuberculosis Association, has adopted a report of its Subcommittee on Immunology which recommends that "efforts be continued to perfect and to meet in practice suitable standards for the production of B.C.G. vaccine, and that, when practicable, commercial firms be licensed under the National Institute of Health to produce the vaccine."

WITH WHALES AND SEALS

BY

H. R. LILLIE, B.Sc., M.B., Ch.B.

Surgery and medicine on Arctic or Antarctic expeditions are very different from the routine of practices and hospitals in cities. In lands where icebergs drift quietly by in the summer twilight and the world next day may be one howling gale, you are your own radiologist, pathologist, and theatre sister, and for a second opinion you have the nearest penguin or polar bear. When an operation has to be done, the ship's fifth engineer will probably be first assistant and one of the wireless operators anaesthetist. Then the patient so often gets back to duty in much less time than he would at home, for the air is pure and he knows his mates are waiting for him.

Surgeons and biologists on whaling operations, and those who come in contact with the lesser-known sealing expeditions, soon realize that behind the popular sagas of hardships and bravery in these industries lie killing methods which over the past hundred years have, for excesses of cruelty, been surpassed only by the horrors of fur trapping.

Whaling in the Antarctic

My introduction to the real state of affairs in whaling was in the Antarctic in the 1946–7 season as surgeon with a Scottish whaling fleet of 14 ships, comprising the parent factory ship the size of the *Empress of Australia*, 10 foraging harpoon vessels like squat trawlers, two oil tankers, and a supply ship plying between the mother ship and the United Kingdom during the season. Six hundred men had to be catered for medically. It was a year when the accident toll was heavier than usual, one catching-vessel being lost with only one survivor, and the fleet hospital on board the mother ship was kept in action with such as broken limbs and ribs, eye damage from a tank explosion, and, by the way of variation, injuries to a flenser who fell inside a blue whale's mouth as the carcass was being turned over on deck. Trapped with only his boots sticking out as the jaws came together, he got off with a moderately crushed chest and emphysema from the neck to the waist, but was back on his job in six weeks. In a factory ship crammed from stem to stern with machinery for processing the whales, with little room for men to move around, accidents were to be expected, but mangled feet and hands were very few. In view of the antiquated explosive harpoon still used in the killing, which bursts the whale intestines, a large supply of anti-gas-gangrene serum was taken, but little was required in spite of whales having to be handled at times in a very putrid condition.

A whale-factory cutting-deck, which for space resembles the flight deck of a small aircraft carrier, when in full action is a blood-soaked welter of entrails, massive vertebrae, ribs, jaw bones, and five-ton lumps of red meat being dragged in all directions. The whale being dismembered may have been well over 100 tons in weight, the equivalent of 150 oxen. The surgeon acting as biologist in the pursuit of whale pituitaries, ovaries, pancreas, or thyroids has to find his specimens with the minimum of delay in this battlefield if he is to secure them before they disappear through the deck manholes into the factory cookers below. And if his feet go out from under him on a piece of slippery whale tongue, then the mirth of those seeing him sitting in six inches of blood and entrails is anything but half-hearted.

The ship's hospital equipment was good. There were eight normal beds, two extra isolation cabins for emergency, and an operating theatre equipped for every possibility: a portable *x*-ray plant was a great asset, and, in addition to its use for humans, was used to diagnose damage done to the foot of one of the many king penguins we brought back from South Georgia for the zoos in Britain.

The whaling surgeon is likely to be busy at any time in the day or night throughout the three to four months' active whaling season. During daylight most of his work will be with the factory hands, but at night catching-vessels will come alongside to take on bunkers and stores and get any sick men attended to, for only with very serious cases will they interrupt whaling operations. In addition to accidents there are always the few dental cases requiring fillings or extractions. The fevers also crop up. A week out from home we had a case of scarlet fever on board, and towards the end of the season one of the worst cases of chicken-pox I have seen. During the season the doctor may transfer to the catching-vessels for a few days at a time, keeping in touch with the mother ship and the other catchers by radio-telephone.

The method still used in killing the whales to-day is antiquated and horrible. Since the last war radar, asdic, and even aircraft have been added to the whalers' equipment, in addition to faster catching-vessels, but the sad fact remains that with all these inventions the actual killing with the explosive harpoon is more cruel and economically unsound than was the original iron harpoon at the dawn of the industry hundreds of years ago—more cruel than it would be to a man, for, in a whale, wound shock gives no relief; and economically bad, for the explosive harpoon is the most wasteful weapon possible. The delayed-action explosive head usually bursts the intestines and spreads putrefactive organisms throughout the circulation during the long time taken for the creature to die. Only in the comparatively few cases when the whale is speedily and humanely killed by a harpoon striking a vital spot altogether away from the intestines can satisfactory meat be produced. Only when this primitive explosive harpoon is given up altogether—superseded by a modern humane method such as electrocution—will whale meat ever really come into its own as a valuable food for man.

A whale swimming is a wonderful sight, just the poetry of majestic motion, and to see one of these beautiful creatures pouring blood and gasping along on the surface towing a three-hundred-ton catching-vessel on the end of a harpoon rope is pitiful. Anything up to an hour is the usual time taken for them to die, but time and again it takes two or three hours and three, four, or more harpoons to tear and blast the life out of one of them. In one extreme case I witnessed five hours and nine harpoons were required to kill a female blue whale in advanced pregnancy. These mother whales fight desperately for their lives and those of their babies. I am glad to say research to correct this is at long last going ahead to make the industry one of which we need no longer be ashamed.

Sealing Expedition

Last Christmas brought me to Newfoundland and a base at Twillingate Hospital in Notre Dame Bay, an institution of 130 beds serving an area of 3,000 square miles and presided over by Dr. John Olds, a graduate of Johns Hopkins. There we discussed the plight of the harp seals and what could be done. Like the whales they are helpless against uncontrolled commercial exploitation. The sealing fleet this past spring included 25 ships from Newfoundland, Norway, Canada, and the United States, and one was fitted as an emergency medical ship. Two spring months were spent in the drifting pack with the seals, our little wooden vessel

Codroy with her crew of 43 men at times lying immovably jammed and helpless in a silent world of drifting snow, or on other days with the pack grinding and battering at her sides in a heaving ocean swell Three ships were lost—one wooden Newfoundlander, from which the crew escaped, was crushed by heavy inshore rafting pack, and two steel Norwegian ships were lost by fire and heavy seas, the crews of both missing.

The conditions of medical work differed from those on the whaling expedition. Other ships of the fleet could not come for medical help, being often frozen fast in the pack and possibly 50 miles away from us. So we treated over our radio transmitter their cases of pneumonia, damaged ribs, and exposure. A mild form of snow blindness was common in men who neglected to wear dark glasses while working in bright weather out on the ice pans. Seal finger, sometimes known as fat finger, is found occasionally in men working with adult seal pelts. Dr. Olds has probably studied this more than anyone. In appearance the lesion is not unlike a tuberculous finger; it is confined to the joint and does not spread, and there is no accompanying lymphangitis. But there is ultimate necrosis and atrophy of the bone, when amputation is the only effective treatment. Investigation by Dr. Olds has shown that in cultures from such fingers, as well as from the seal parts involved, the dominant organism is frequently a staphylococcus, but the bacteriology so far is not conclusive. I found a break in the skin was not a necessary preliminary. Very often the fingers involved are those hooked into the eye-holes in dragging the adult pelts over the ice, and possibly mechanical pressure forces the organisms of the skin through to the deeper layers. I have never seen a similar condition during any whaling operations. In the three typical cases of seal finger brought to me penicillin was injected into the joint area and streptomycin systemically. The two with which I was able to keep in touch cleared up well, but the third patient lost his life by drowning.

Unnecessary Cruelty

As in whaling, unnecessary cruelty is inflicted on the seals. The baby harp seals (whitecoats) born out on the pack ice are helpless, and are taken mainly for their fat; often, instead of killing them properly by a blow on the skull, sealers just daze them with a kick before cutting the little bodies out of the pelts. The mothers climb back on to the ice and wonder why the bleeding carcasses cannot suck from them.

Days I spent with ciné and other cameras strapped around me jumping ice pans; with the ocean swell, footing was not always safe. Many times I subsided into the icy water, when first thought had always to be for saving the cameras, and fortunately only one of three came to grief. On one occasion a harp seal being chased close by was caught between two closing pans and burst like a ripe tomato. I was more careful than ever after that. In this work, often miles away from the ship, I found drinking raw seals' blood and eating the hearts raw to be the most sustaining food of all. It is the Eskimo way.

The shooting of the adult seals later in the season is the worst of all, when any man who thinks he can shoot is allowed to mutilate these creatures. Some seals may die at once, but others shot through the neck or lungs writhe about until they may flop over the edge of the ice to die out of sight. I have seen as many as five seals from one pan disappear leaving bloody trails, while others crippled lie in pools of blood. Three hundred thousand seals are involved annually off Newfoundland alone, and international control is urgent.

Why has nothing been done in the past towards humane whaling and sealing? I find so many of the whalers, sealers, and trappers in their hearts are sick of the practices of these industries, so often glamorized in print. As medical science seems to strive towards the survival of the unfittest, and wider famine areas result from the excessive increase in human numbers, consideration for the other animals that are helping us out now is more than overdue.

Everywhere I have been apart from Arctic and Antarctic expeditions the great cry both in the cities and the remote backwoods is for all-round doctors, with a grip of medicine and surgery as a whole—men to whom the people can come knowing they will be taken care of mentally and physically and not just pushed on to someone else. There are so many vast areas where a Highlands and Islands Medical Service as we knew it in Scotland is an urgent need. But the people living bravely in the outposts of this world will for ever resent any so-called free service. There they rarely complain of their lot. They may be lonely, but the general doctor can do much where the city specialists' ideas cannot meet the requirements. These people have faith in what they are doing, and courage Working with them you will get back again your faith in the human race.

AUREOMYCIN AND CHLOROMYCETIN

We published (November 19, p. 1171) a memorandum from the Ministry of Health on the subject of "aureomycin" and "chloromycetin." The Department of Health for Scotland has now made the following announcement:

Supplies of aureomycin and chloromycetin are now available for use in Scotland. Owing to the fact that they are scarce and costly their use can be justified only for conditions in which they are likely to be beneficial. Until supplies become more plentiful the Medical Research Council has advised that the use of the drugs should be confined to the following conditions:

Aureomycin.—Suspected cases of ornithosis; proved cases of undulant fever (brucellosis) and lymphogranuloma inguinale; severe cases of atypical pneumonia in which there is good reason to believe that the cause is a virus.

Chloromycetin.—Suspected cases of ornithosis; proved cases of undulant fever (brucellosis), lymphogranuloma inguinale, typhoid fever, paratyphoid fever (severe), salmonella septicaemia.

These categories are under constant review and may be added to from time to time in the light of current expert advice.

All available supplies are being purchased centrally and will be distributed through the following centres:

Region	*Distribution Centre*	*Telephone No*
Northern	The Medical Superintendent, Raigmore Hospital, Inverness ..	Inverness 681
North-Eastern ..	Dr J. Smith, City Hospital, Aberdeen ..	Aberdeen 2242
Eastern	Dr. Wm. Jamieson, King's Cross Hospital, Dundee	Dundee 85241

Western	The Chief Pharmacist, Central Pharmaceutical Store, 112, Ingram Street, Glasgow ..	Glasgow Central 9600

THE CONTROL OF SCABIES

with

'TETMOSOL'

TRADE MARK

TETRAETHYLTHIURAM MONOSULPHIDE

'TETMOSOL' is a powerful sarcopticide, and in the forms of 'Tetmosol' Soap and 'Tetmosol' Solution has proved highly effective in both the prophylaxis and treatment of scabies.

The Solution (25%), diluted with water before use, provides a most satisfactory and certain method of treatment. It produces a rapid cure of scabies and has the advantage that its application is painless and rarely gives rise to dermatitis.

'Tetmosol' Soap—a pleasantly perfumed soap tablet containing 5% tetraethylthiuram monosulphide—is primarily intended for prophylactic use against scabies. It has proved especially valuable for controlling outbreaks of the disease in families and in communities such as asylums, hospitals, schools, etc. The method of use is simple and convenient so that the co-operation of the scabies patient is readily secured.

'Tetmosol' Solution (25%). Bottles of 100 c.c., 250 c.c. and 2 litres.
'Tetmosol' Soap (5%). Single 3 oz. tablets and boxes of 36.

Literature and further information available, on request, from your nearest I.C.I. Sales Office—London, Bristol, Birmingham, Manchester, Glasgow, Edinburgh, Belfast and Dublin.

Write for full particulars and synopses of films on free loan from the I.C.I. Film Library, Bolton House, 61 Curzon Street, London, W.1

Viscopaste and Ichthopaste Bandages

Viscopaste and Ichthopaste bandages are recommended as an alternative to elastic adhesive bandaging, in the treatment of chronic varicose and eczematous conditions and where the patient's skin is hyper-sensitive. Both bandages have non-fray edges and are thoroughly impregnated with zinc oxide gelatin paste of the Unna type. Ichthopaste contains, in addition, 2% Ichthammol.

Available in 6 yd. lengths by 3½" wide.

Descriptive literature may be obtained on request to the Medical Department of the Manufacturers.

VISCOPASTE & ICHTHOPASTE Bandages *are made in England by T. J. Smith & Nephew Ltd., Hull*

Reports of Societies

MUSIC IN PSYCHOLOGICAL MEDICINE

The use of music in psychological medicine was discussed at a meeting of the Section of Psychiatry of the Royal Society of Medicine on December 13, with Dr. W. J. T. KIMBER presiding.

Dr. S. D. MITCHELL said that at his mental hospital, with a colleague, he had been studying the use of music in group therapy in a variety of syndromes. The groups averaged 10 persons, all in-patients, members of both sexes, mainly young and middle-aged adults, generally selected because they liked music and were well enough to carry on a conversation. They met weekly, listened to selections of music, and discussed their reactions. He wanted to see whether the more inhibited were enabled to express themselves better, and whether the less inhibited would have better emotional control. The music was chosen to cater for every taste. Elizabethan music—madrigals and so forth—appeared to be too remote to evoke any emotional reaction. Reactions to the music of the great composers varied:

Mozart.—Mild serenity throughout the group.

Bach.—Some patients were indifferent. Several schizophrenics expressed "cool admiration." One declared that the composer was "balanced." An anxiety neurotic and morphine addict found this music boring; Bach gave her, she said, a feeling of frustration and inferiority.

Beethoven.—Produced outstandingly stimulating effects compared with other classical masters. On listening to the Fifth Symphony a manic-depressive said it was clear that Beethoven had had a conflict and had won through. It made her feel much better to listen to him.

Chopin.—An obsessional neurotic said that the Fourth Prelude affected him personally; a manic-depressive woman had a feeling of personal loss. A young schizophrenic said that Chopin's music burdened her with other people's troubles, and she did not see why this should be.

Wagner.—The *Flying Dutchman* overture evoked very strong personal reactions and led to quarrelling about personal attitudes to the love relationship.

Nineteenth-century realistic music, said Dr. Mitchell, had certain advantages in therapy. It stirred up personal emotional reactions, but it did make for contact with reality. Negative transference was frequently aroused in the personal relationship of group members. A selection from *Cavalleria Rusticana* led to animated discussions on the faithlessness of men and of women.

Schizophrenics showed kinship with Eastern music. The reactions to comic and light music were stereotyped and much like those of normal people. Of Stravinsky's ballet music a morphine addict said that if she had been present at the ballet she would not have been responsible for her behaviour; a paranoiac said that the composer should be shot. The music of Delius affected patients favourably, but some felt it was "like a cold wind." Traditional and folk songs drew the group closely together.

On the whole Dr. Mitchell thought that these preliminary investigations were sufficiently encouraging to justify the further use of music as an accessory in psychological medicine. Even deteriorated patients responded well to music and afterwards talked more freely and sociably.

Reactions of Mental Patients

Dr. E. CUNNINGHAM DAX exhibited a number of paintings made by patients immediately after hearing certain musical compositions. He considered that the therapeutic uses of music were spoken about too loosely. No one had proved statistically that music or any other art had a curative effect on the mentally ill, yet people tended to speak of stimulating or sedative music as one might speak of drugs. He went on to play a gramophone record of a composition by a patient; this consisted of 16 variations on "God rest you merry, gentlemen." He also showed the original notation, which was in part illegible. When these variations were played back to the patient two years later she disowned some of them. He also showed a musical score by a young and distinguished composer who was a schizophrenic. He had decorated it with various emblems, and the notation itself appeared to be schizophrenic in character. Scores by other patients showed decided overactivity.

As to the reactions expressed pictorially after listening to well-known music, Vaughan Williams's "Lark Ascending" appeared notably to increase the colour reactions of the patients, and Schumann's "Pianoforte Quintette" increased the sense of movement. After hearing one piece of music, 13 out of 17 patients immediately depicted scenes of murder, suicide, robbery, train disasters, storms, or dragonflies burning their wings in the fire. Dr. Dax added that at concerts patients seemed to enjoy the voice, especially the soprano, more than instruments. A more disturbed group was greatly upset by the piccolo, but as yet no patient had had a fit during a concert.

In the ensuing discussion some interesting experiences were exchanged. One psychiatrist who had trained an orchestra of mental patients said that it had opened to them a new dimension. Some of the patients even simulated the mannerisms of professional musicians.

Dr. WILLIAM SARGANT spoke of experiences in the Southern States of America where among the negro populations music was essential to church worship, and church worship was intimately bound up with psychiatric healing. He had seen what amounted to shock therapy produced by musical noise and excitement. He referred also to the history of St. Vitus's dance, which, like the tarantella in Italy, was a dance used in the Middle Ages for working a hysterical malady out of the system

Dr. HENRY YELLOWLEES put in "a humble plea for clear thinking." The only point the openers had made was that music provided a means of emotional expression for the patient. Various diagnostic labels had been placed on patients, but surely inhibited schizophrenics and the like would all react in some way or other to any stimulus, and there was no evidence that there was any validity whatever to be attached to the reactions which occurred after the playing of certain pieces of music.

Jung would have given these patients a string of simple words, and surely they would have shown just as varied and sometimes startling reactions as they had done to musical compositions. Moreover, all the three schools of psychological medicine had laid stress on the point that what mattered was the individual psychology of the patient, his individual complexes and outlook, yet now for various reasons patients were treated in groups, and we had "social psychiatry, social psychology, and social everything else." Here inferences were being drawn from the reactions of a group of psychotic or neurotic or psychopathic patients, all mixed up together, who, after a certain piece of music had been played to them, were said to be more group conscious.

Dr. MITCHELL, in reply, said that he thought those who had experience of what had been done would agree that there were advantages, both for observation and treatment, in the musical group method.

MANAGEMENT OF THE ANAEMIAS

At a meeting of the Liverpool Medical Institution on December 1, with the president, Professor Charles Wells, in the chair, Dr. F. J. ZACHARIAS read a paper on "The Management of the Anaemias."

Dr. Zacharias said that the general practitioner had to sort out those cases he could treat himself and those that required investigation in hospital. Domiciliary management was adequate for a large number of cases, those in which the anaemia was doubtful or slight and whose symptoms did not suggest serious organic disease, and also those in which the history and signs suggested an iron-deficiency state but with no likelihood of persistent blood loss. Access to the laboratory for every practitioner was essential, and the importance of full co-operation between the general practitioner and the pathologist was stressed.

The speaker suggested that in many hospitals far too little was done in the out-patient clinic. It was his practice to have a full blood count and a histamine test-meal undertaken, and to perform a sternal puncture on out-patients in a single morning, as a routine in all cases of anaemia requiring these investigations.

The problems of investigation in the less straightforward cases were discussed with particular reference to pernicious anaemia. It was relatively common to mistake macrocytic anaemias that did not respond to liver therapy for cases of pernicious anaemia. He recalled a series of such cases seen in the last three years, including cases of haemolytic anaemia, refractory normoblastic anaemia, aleukaemic leukaemia, and certain cases of chronic hypoplastic anaemia.

The less common error of mistaking pernicious anaemia for other conditions was then discussed, and three cases were described presenting in young people with organic heart disease; in each case bacterial endocarditis had been diagnosed. In one of these cases the peripheral blood was at first not significantly macrocytic, and only a full investigation revealed the true nature of the anaemia.

Dr. Zacharias stressed repeatedly the importance of the axiom "Investigate before you treat," and showed that failure to adhere to this principle was responsible for much confusion and delay in diagnosis and for many errors in treatment. While the great majority of cases of pernicious anaemia could be diagnosed by an intelligent assessment of the clinical findings together with examination of the peripheral blood, mistakes would be made occasionally if these cases were not further investigated by means of the histamine test-meal, marrow puncture, and assessment of the reticulocyte response to treatment. Since the outlook was usually very grave in the cases misdiagnosed as pernicious anaemia, this error was inexcusable, for with proper investigation, before and not after treatment, it could be avoided.

Blood Transfusion

Dr. D. LEHANE read a short paper on blood transfusion in the treatment of anaemia. He said that blood transfusion, properly administered with due regard to the indications, gave excellent results in the treatment of anaemia. The main purpose of transfusion was to increase the number of circulating red blood cells. This was necessary when there was complete failure of red blood cell production, when the anaemia was so severe that the patient's life was in danger, or as a pre-operative measure.

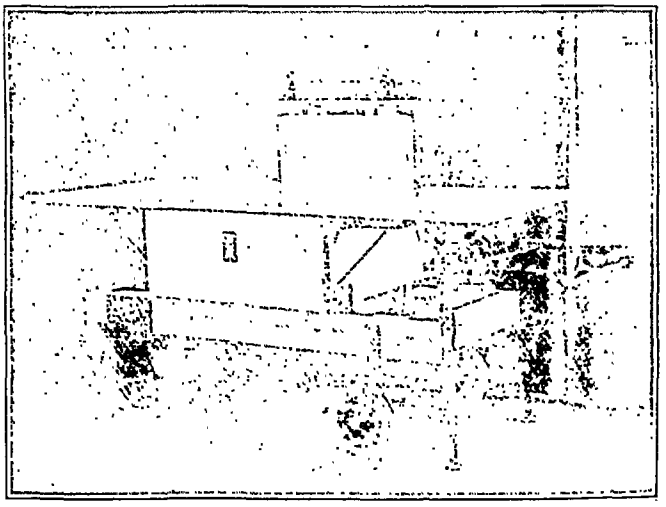
The indications for transfusion in the various types of anaemia were briefly discussed. Cases of chronic hypochromic anaemia usually responded satisfactorily to iron therapy, and transfusion was not necessary except in the most severe cases.

Liver therapy was usually adequate for cases of pernicious anaemia, but blood transfusion was of considerable value when anoxia appeared.

Patients suffering from the macrocytic anaemia of pregnancy could be maintained in good health throughout pregnancy by transfusion.

In cases of aplastic and hypoplastic anaemia blood transfusion was the only measure by means of which a satisfactory haemoglobin level could be maintained; it was possible to prolong life for considerable periods by repeated transfusions. Two patients who had had long remissions had been given 108 and 58 transfusions respectively, and were in good health after three and a half and two years.

Transfusion was of little value in the anaemia of leukaemia except in the preparation of the patient for other therapy. In his experience treatment by massive replacement transfusion had not been very helpful in cases of acute leukaemia.



Generally speaking, single transfusions of not more than 500 ml. should be given on alternate days by the slow drip method. Where there was any possibility of myocardial insufficiency great caution was required, and the rate of transfusion should be 10–15 drops per minute, otherwise there might be grave danger of overloading the circulation. Deaths from pulmonary oedema and cardiac failure were by far the commonest fatal transfusion reactions in cases of chronic anaemia.

Preparations and Appliances

WARD WEIGHING-MACHINE FOR RECUMBENT PATIENTS

Dr. F. HARWOOD STEVENSON, Consulting Physician to the Royal National Orthopaedic Hospital, writes: The weighing-machine illustrated here has been made for the Royal National Orthopaedic Hospital, Country Branch, Stanmore, and is proving most efficient and valuable in use.

There are in the hospital about a hundred cases of orthopaedic tuberculosis. It has long been felt that these and certain other long-term cases should be weighed regularly, and this machine has been constructed so that the patient can be laid recumbent and, if necessary, weighed in a plaster bed or on a frame. All frames and plaster beds are now weighed before the patient goes on to them. The machine weighs up to a maximum of 24 st. (107 kg.) by 2-oz. (57-mg.) divisions, and the total capacity is shown on graduated indexes over which pass sliding poises, there being no loose weights whatever. The indexes are placed so that they can be read by a nurse of average height while standing, and are at the centre of the machine. The weighing mechanism is mounted on a trolley which is fitted with four sorbo-rubber-tyred wheels, two of which swivel to enable the machine to be manœuvred in a

very small space. The stretcher, or platform, is so designed that it cannot tip, and when not in use the ends fold over the centre of the machine, thus reducing the size and making it more convenient to move about. At one end of the trolley is a folding push-bar which acts as a convenient means of pushing or pulling.

When the machine is manœuvred into position beside the patient's bed the handle-bar is pulled down, thereby raising the two back swivel wheels off the ground and lowering two feet, or supports. The front wheels can be secured by a hand-brake, and the machine is then completely stable. All knife-edges and bearings in the weighing mechanism are of hardened steel, thus ensuring the continued sensitivity and accuracy of the machine.

It will be noted from the above description that the whole outfit is fully mobile, and as it is constructed largely of wood the weight is kept to a minimum. It can be handled quite easily by one nurse.

The machine is made by H. Fereday and Sons, Ltd., 39-54 Shaftesbury Street, London, N.1, and the price is £50.

A pamphlet entitled "Cerebral Palsy" has been prepared by Queen Mary's Hospital for Children, Carshalton, Surrey, giving notes for physiotherapists on infantile cerebral palsy. It may be obtained for 1s. from the hospital.

Correspondence

Morphine for the Injured

SIR,—Mr. Wilson Hey (November 5, p. 1056) has done a great service to the profession and the country in drawing attention to the restrictions in the use of morphine which are the cause of unnecessary suffering.

Recently a committee on ambulance equipment, of which I was chairman, was informed that while an ambulance with trained attendants and equipment, including morphine and syringe, usually arrived at the seat of an accident promptly, no morphine could be given until a doctor was obtained, and that there was generally appreciable and sometimes prolonged delay before the services of a doctor were available. The committee made recommendations to the effect that with certain safeguards the law should be altered to permit of trained attendants giving morphine under such circumstances.

During my service in Palestine in 1938, when British troops were scattered in small groups in many villages, R.A.M.C. nursing orderlies were provided with morphine and instructed in the indications for its use, and nothing but good resulted. During the war many units at home and abroad were provided with "tubunic" ampoules of morphine for use when no doctor was available.

Surely the time has come to revise the rules so that they do not stand in the way of relief of pain in emergency.—I am, etc.,

ALEX. HOOD.

Government House, Bermuda.

Sudden Obesity and Psychological Trauma

SIR,—I was extremely pleased that the weight of Dr. H. J. Shorvon and Dr. John S. Richardson's authority should be brought to the support of a concept which I have urged for many years. There are two points, however, in their paper (October 29, p. 951) which I feel might receive a slightly different stress. In the first place, although they quote the work of Verney on the action of the antidiuretic hormone of the posterior pituitary in producing water retention during emotional stress, they do not in their discussion give it the weight which I feel that it deserves. I have not had the opportunity of studying this subject from any but a strictly clinical point of view, but I am convinced that in those patients who develop "obesity" suddenly during emotional stress the water retention is of far greater importance than the fat retention. I have even wondered at times whether any true fat retention in fact occurs. The changes in weight are often so sudden that it is difficult to account for them by fat deposition. Pitting oedema, best detected along the shins, is nearly always obvious and occasionally severe.

My second point is a corollary to this. The authors in their discussion of their case lay great stress on the excellent researches of Bruch. No one, of course, can deny that "oral gratification may allay anxiety or conflicts," or, as some of us would put it, that food is a comforting thing. I have no doubt that many people who are unhappy over-eat and that this is particularly true of children. Nevertheless the case of my own which Dr. Shorvon and Dr. Richardson quote brings out an important point about this syndrome which is too little stressed. My patient lost weight only slightly on a diet of 1,000 calories under close observation while her anxiety continued. On a diet which must have had at least twice this calorie value, and perhaps three times, she lost weight very rapidly when once her anxiety had ceased.

The increase in weight due to psychological trauma is not invariably associated with an increase in appetite or with an increase in calorie intake. This apparent contradiction of the law of the conservation of energy can only be explained on the assumption that the major part of the increase is due, as it is in Verney's animals, to water retention rather than to fat deposition. On this hypothesis it is easy to understand why so many of these patients fail to lose weight on a diet of restricted calorie value while they lose weight rapidly on a diet which restricts their intake of carbohydrate, fluid, and salt, leaving their calorie intake more or less unaffected. It explains also why diuretics are often a necessary part of the treatment.

Dr. Ian Martin-Scott (November 19, p. 1178) raises the question of whether seborrhoeic dermatitis is a related phenomenon. I cannot bring forward any statistical observations. My impression is that although seborrhoea is commonly associated with psychogenic obesity it is probably no more common amongst the obese than amongst the slim. Nevertheless it is a very noticeable fact that when seborrhoea is associated with obesity it is immensely improved by the dehydrating regime.—I am, etc.,

RAYMOND GREENE.

London, W.1.

SIR,—We were much interested by the question asked by Dr Ian Martin-Scott (November 19, p. 1178). We have considered our cases in the light of this question but have found no evidence of excessive secretion of sebum as a constant or even frequent feature. It was notable that many of our patients had particularly fine clear skins such as are not infrequently seen in obese subjects.

Dr. Martin-Scott presumed that the loss of weight in our cases was due to fluid loss. This we feel is most certainly true when the loss is rapid, but we have also found that our patients had better control of their appetites after the treatment we were giving.—We are, etc.,

H. J. SHORVON.
J. S. RICHARDSON

London, W.1.

Amphetamine Euphoria

SIR,—The case recently reported in the press, when a young woman committed shop-lifting offences apparently under the influence of amphetamine euphoria, is perhaps of more than passing interest. In the circumstances it was not unexpected that the magistrate declined to accept the suggestion that the drug had any effect on the girl's behaviour, and as there is little reference in the literature to the association of amphetamine ingestion with delinquency the facts should be placed on record.

The patient, a young woman of 24, asked for medical advice concerning her varicose veins. In relation to these the principal causative factor appeared to be her excessive weight, and as she slept long hours and was rather lethargic and apathetic generally amphetamine 5 mg. three times daily was prescribed.

It was on the third day after beginning the drug treatment that the offences took place. As she was going out for the afternoon she decided on her own account to take two tablets at lunch-time. As she was not hungry and thought that fasting would help her to lose weight she had eaten nothing since breakfast. Her memory of events during the afternoon is vague, but it appears that, as arranged, she met her sister, who after a time noted her strange excitable mood and tried to persuade her to return home. Five articles were stolen in three different shops, and it was only in the last shop that the sister became definitely aware that something had been stolen and tried in vain to get her to replace it. Shortly after she was detained by the stores' detective, who in giving evidence testified that the girl laughed and treated the matter as a joke and did not appear in a normal mood.

There was nothing to suggest psychological stress, nor had there been any indication of delinquent characteristics or of maladjustment of any kind. On the day before the offence she had appeared somewhat jovial and irresponsible, but not to an extent to draw particular attention. She had slept fitfully, unlike her normal routine, had jumped out of bed easily in the morning, and stated that at midnight "she felt like going off to London for a night out." At the court hearing it was reported that Dr. Russell Davies had found, during an investigation in the Services, that women were more liable than men to show a tendency to irresponsible behaviour, without normal control or insight, after amphetamine medication. It would be interesting to know if there have been other cases of this kind.—We are, etc.,

ALAN MABERLY.
C. V. BLOOM.

London, E.

Experimental Ascorbic Acid Deficiency

SIR,—I am most interested in the medical memorandum by Dr. J. D. Andrew on experimental ascorbic acid deficiency (December 3, p. 1273), especially in the observation that he had oedema of the ankles apparently due to ascorbic acid deficiency. Out of the mass of literature on the subject I quote Duran-Reynals,[1] who states that "the studies of Chambers[2] and Zweifach[3] have defined the cement present between the endothelial cells of blood capillaries as a sticky, argyrophilic matter, continuously secreted by the cells themselves, and conditioned by calcium salts and the *p*H level. The cement behaves as if it were a salt of calcium, is digested by trypsin, and is not laid down in the absence of vitamin C."—I am, etc.,

Visceral Actinomycosis

SIR,—Mr. V. Zachary Cope, in his Bradshaw Lecture on "Visceral Actinomycosis" (December 10, p. 1311), brings to our notice the Cinderella of infections. He is to be congratulated on his clear exposition of the disease, its symptoms, diagnosis, and treatment, and in stressing the need to bear this disease in mind at all times. It is only by being alive to the fact that this disease is not a rarity that it will be diagnosed and the necessary treatment carried out. Both surgeon and bacteriologist have a responsibility in the diagnosis of this condition—the surgeon to include it in his differential diagnosis and to provide a suitable specimen for bacteriological examination, the bacteriologist to search for and isolate the causative organism.

To isolate *A. israeli* and grow it in pure culture is often a difficult task for the bacteriologist. If a small quantity of pus arrives on a swab then the job of the bacteriologist becomes much more difficult, if not wellnigh impossible, unless the "sulphur granules" are abundant. Pus obtained from any lesion which is suspected of being actinomycotic in origin should be sent to the laboratory in a sterile tube and not on a swab. The more material that is sent to the bacteriologist the better chance he has of finding the organism.

Although much has been learned about this disease since the first case was described 70 years ago, there are still many gaps in our knowledge. The fact that *A. israeli* could be isolated from the teeth and tonsillar crypts of people who showed no signs of actinomycosis was an important contribution to our knowledge of the disease, as was the fact that the disease was often associated with dental caries. It has long been recognized that trauma frequently precipitates the onset of the condition. These three factors—actinomycetes in the mouth, dental caries, and trauma—must often be present in the mouth. It may be that other factors are required before *A. israeli* can establish itself in the tissues. It is probable that actinomycosis is a commoner disease than we realize, only a small proportion of the actual cases being diagnosed.

The figures of the incidence of actinomycosis in this country were given in a discussion at the Royal Society of Medicine in 1930 by Cope.[1] In 11 hospitals in England the average number of cases per year varied from 1 to 2.5. In two of the largest Scottish hospitals there had occurred only five cases in ten years and eight cases in nine years respectively. Recently a survey has been carried out of the cases of actinomycosis which have occurred in the North-east of Scotland (the results of which it is hoped to publish shortly), and it would appear from this that the incidence of actinomycosis, at least in this area, is much greater than the figures quoted above. This survey is part of an investigation the results of which it is hoped will provide figures of the incidence of actinomycosis in Scotland.—I am, etc.,

Treatment of Cutaneous Anthrax

SIR,—With reference to recent correspondence on anthrax (October 15, p. 875, and December 3, p. 1296) the following fatal case of anthrax might be of interest.

A Slovak peasant of 50 cut a finger of his left hand while handling some raw meat. Soon his hand became swollen, and his general condition deteriorated so rapidly that on about the third day of his illness he had to be transferred to a hospital. On admission he was a very ill man, semi-comatose and running a temperature of 104° F (40° C.). He died about 24 hours after admission, receiving symptomatic treatment only.

The most important necropsy findings were: (1) Left arm oedematous. (2) Lymph glands of left arm, left axillary, and cervical glands enlarged and haemorrhagic. (3) Spleen enlarged, soft, septic. (4) Haemorrhagic exudate in pleural cavities and haemorrhagic bronchopneumonia of both lungs. (5) Haemorrhagic leptomeningitis; the thickened meninges were covered with a thick layer of brown-red haemorrhagic exudate. Direct smears from the meninges showed numerous anthrax bacilli, which were grown from cultures from the organs also.

This case, an example of the fulminating type of anthrax giving rise to septicaemia and haemorrhagic leptomeningitis, did not receive penicillin. However, several cases of malignant pustule of the arms and face responded well to treatment with penicillin.—I am, etc.,

London, W.C.1. I. FRIEDMANN.

Antihistamine Drugs and Sea-sickness

SIR,—It is a matter of some difficulty for the ship's surgeon to assess the many and varied remedies for this distressing complaint, and the reasons are not far to seek. The passenger usually consults one after vomiting for 24–36 hours, and this often coincides with the end of the bad weather. So whether it be the passenger finding his sea-legs, the weather subsiding, or the efficacy of the remedy prescribed which causes his vomiting to cease is hard to determine. One must remember, too, that one only sees the failures and not the successes of the self-medicated travelling public.

During the war a considerable amount of research work was undertaken to find a remedy for sea-sickness, but in the end hyoscine by itself or combined with some other drug was found to be the best antidote. In fact one might say that until a year ago hyoscine was the sheet-anchor in the treatment of sea-sickness.

The first report on "dramamine" (see leading article in the *British Medical Journal*, May 14, p. 855) seemed almost too good to be true, though it should be noted that quite a considerable proportion of the controls fared quite well on the placebo given, stressing the psychological factor, which is very considerable in this complaint. I have treated a considerable number of cases with dramamine and its Canadian equivalent "gravol" during the summer months when the weather was not too bad and have been very favourably impressed, though my results were not as good as those published by the Americans.[1] However, any antidote for sea-sickness given by the mouth presupposes that the patient will retain it, and in their inability to do so probably lies most of my failures.

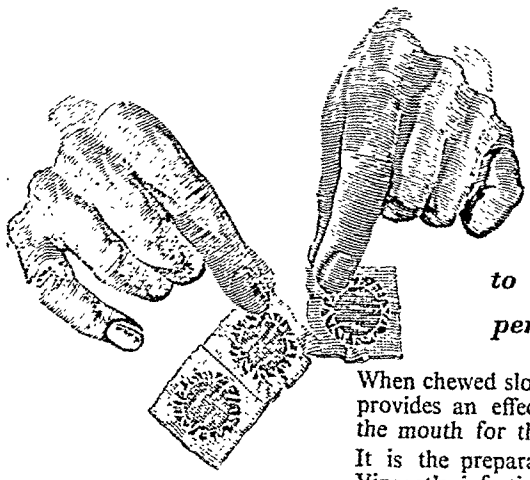
The first aim of the surgeon in treating sea-sickness is to stop the vomiting, the second to alleviate the accompanying dehydration. In order to accomplish this I consider it is of cardinal importance to commence medication per rectum. The weather this autumn on the North Atlantic has been very favourable to an extensive trial of initial rectal therapy. The last two voyages westbound found us in a whole gale for three days, which means considerable pitching. In most cases medication had commenced 24–48 hours before the storm subsided, an important point in assessing the results. One hundred cases of severe sea-sickness were treated, and below is given the routine and the results.

Patients were kept in bed for two days. Initially one "neoantergan" suppository (150 mg.) was given per rectum, and a half-hour later the patient was encouraged to commence slowly drinking either water, ginger ale, or soda water, aiming at an intake of four to five pints (2.25 to 2.8 litres) during the following 24 hours. On the second day light solid diet was allowed, and the fluid intake was maintained as during the previous 24 hours. On the third day the

'ANAHÆMIN' The *established* treatment for pernicious and other macrocytic anæmias

EVIDENCE is accumulating that the therapeutic action of liver extract in pernicious anæmia depends upon the presence, not only of a primary factor, vitamin B_{12}, but upon the presence also of accessory factors (*J. Clin. Invest.*, 1949, 28, 791). For most cases of pernicious anæmia, therefore, whether complicated with subacute combined degeneration of the cord or not, Anahæmin is recognised as the preparation for effective treatment; this is acknowledged by the pre-eminent position it has held for more than a decade. Every batch of Anahæmin is clinically tested before issue.

'ANACOBIN' Solution of PURE crystalline vitamin B_{12}



Occasionally, cases of pernicious anæmia arise which cannot be treated satisfactorily, even with Anahæmin, because of hypersensitivity. For such cases Anacobin is available.

Further information is available on request.

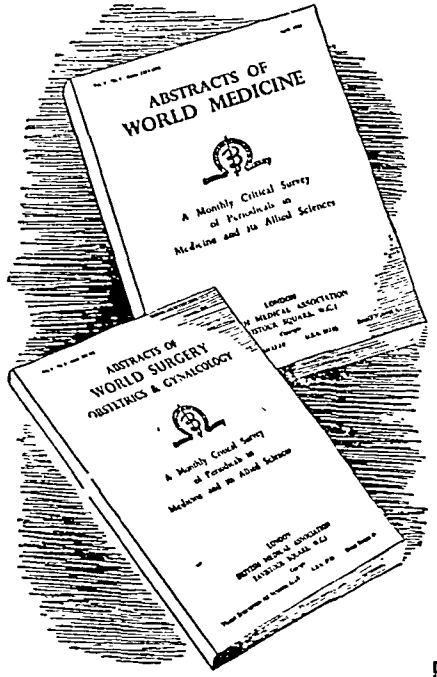
POSITIVELY

NO ADMITTANCE



A sterile technique allows POSITIVELY NO ADMITTANCE to the bacterial invader. In the operating theatre, surgeon and sister preserve meticulous asepsis of materials. Yet in this vital issue they are reliant upon the indispensable contribution of their invisible ally—the suture manufacturer. Modern production methods, with scientific sterility control of every phase of manufacture, merit their *complete* confidence in sterility of the suture. The sealed tube is the final guarantee. Once broken, the aseptic suture is brought safely into the theatre sterile technique. These things assured, the patient is secure with surgical skill in confident hands.

patient was encouraged to get up. Eight hours after the initial suppository a tablet of neoantergan (100 mg.) was administered, and on the second day this was repeated at 8 a.m. and a tablet of "phenergan" (25 mg.) was given at 6 p.m. It was unusual to have to carry on treatment for more than three days. In children the same routine was followed, aiming at a fluid intake of 2 to 3 pints (1.1–1.7 litres) of fluid in the first 24 hours. Initially a neoantergan suppository (50 mg.) was given, followed by pulv. neoantergan (25 mg.) three times a day.

Out of 100 consecutive cases of severe sea-sickness treated in this way only two vomited after the first suppository (one being a foreigner whose language I could not speak, and whether or she followed my directions I cannot tell). The average duration of vomiting prior to medication was 36 hours. Of the 100 passengers treated 80% were females, 20% males. Of these, 20% sought advice following the failure of hyoscine medication, and 7% following failure to retain dramamine tablets. Apart from some drowsiness, I came across no complications.

It is heartening to know that when one first sees a case of severe sea-sickness one can say with almost complete assurance that the patient will vomit no more.—I am, etc.,

Chilblains

SIR,—Dr. J. T. Ingram's excellent article (December 3, p. 1248) on this subject ends by recommending that the physical factors concerned should be explained to the patient. As I have not yet heard or read of a satisfactory explanation, or indeed met anyone who has, I hope you will allow me to give my own as briefly as I can.

1. Chilblains are found usually on such sites as the fingers, toes, and ears. These regions do not contain any intrinsic source of heat. Any animal warmth that they possess is derived from warm arterial blood.

2. The arteries supplying these parts lie to some extent of their course close to the skin surface and are subject to cooling in certain conditions.

3. Heat produced in the body by metabolic processes is largely dissipated by radiation and evaporation from the skin, the hands and feet being especially important in this connexion. It has been shown that a slight rise in body temperature will increase the flow of blood to the hand by 100%.

4. If the body generally is cooled arterial supply to skin, hands, and feet is cut down. Where arteries themselves are exposed to cooling this is bound to result in the blood contained in them being reduced to a lower temperature still.

5. Vascular endothelium being sensitive to cold, the next stage is a spasm of the arterioles supplying the chilblain areas, and ischaemia results—cf., dead fingers after a swim in cold water. So far no great harm has resulted, as tissue metabolism is also arrested by the lowered temperature of the chilblain area.

6. If the subject is so unwise as to warm the part before warming himself the local metabolism will begin before the circulation has resumed. *Hinc illae lacrimae* (meaning, here come chilblains).

As to prevention, it should be clear that groins, knees, ankles, axillae, elbows, and wrists need to be kept warm in cold weather. Wrapping up hands and feet cannot possibly help if arterial blood is already cold when it gets there. If the ears are affected a warm high collar would help. Incidentally, any protective clothing of this sort must be kept dry. A wet anklet is worse than useless. Any measures calculated to increase metabolism should help, particularly an increased calorie intake. The better nutrition.

Regarding treatment, the calcium theory is most interesting. Has anyone ever been cured of chilblains by taking calcium? Does anyone know how the idea started? It is plain enough that a prolonged course of treatment started in March ought to give results by July, at least in this country, by any method, but why calcium? And, I might add, why calcinosis as a sequel of chilblains?

There is one way of aborting chilblains in the itching stage that can be depended on. The patient puts the affected part under a cold-water tap until the part becomes then rubs vigorously with a dry rough towel until the circulation returns. It is essential for the patient to do the work himself and thus get warm. Personal experience of the method has always been quite successful. The last time tried would be about 1934. I am glad to say I have not had chilblains since.—I am, etc.,

Shipley, Yorks.

The Natural History of Asthma

SIR,—I had felt the same disappointment as Dr. D. H. Irwin (December 10, p. 1354) at the absence of adequate reference to psychogenic factors in asthma in the article by Drs. Elsie O. Williams and G. E. O. Williams (October 22, p. 897). One interesting point which Dr. Irwin raises is the "growing out" of the condition which seems to happen round about the age of early puberty. This tendency, of which, so far as I know, there is no statistical demonstration, renders it difficult to assess results of treatment in later childhood, but in my experience residential open-air-school treatment for a period of about two years has very good results and often breaks down the anxiety-ridden cycle at home in the most effective manner.

With younger children re-education of the mother, as mentioned by Dr. Irwin, should be an essential adjunct of any treatment. Finally, a demonstration of its psychic nature is given by the favourable effect of hypnotic treatment in adults. It is possible not only to relieve the nervous spasm during an acute attack but also to obtain extended amelioration by including this particular technique in the therapeutic approach.—I am, etc.,

C. BURNS.

Edgbaston, Birmingham.

The Uses of Streptomycin

SIR,—Your leading article (November 12, p. 1098) on the uses of streptomycin was well timed and informative. Like Dr. Eric Frankel (November 26, p. 1229), however, I find reason to disagree with the statement that the drug is useless in the treatment of ulcerative colitis. Realizing quite well that one or even two swallows do not make a summer, nevertheless they do make one think that others may be knocking around if we look for them.

In October, 1948, a female patient aged 37 was referred to me for hospital treatment. There was a history of the passing of blood and mucus per rectum for some weeks prior to admission, with rapid weight loss and pyrexia. Over the previous six months two similar but shorter attacks each lasting about one week had occurred. On admission the patient was nervous and depressed. Her general condition was poor. Temperature varied between 100°–103° F. (37.8°–39.4° C.). Tenderness was present over the descending colon, and stools (10–20 in 24 hours) consisted of blood, pus, and mucus. Barium enema revealed a straight, narrow colon, and sigmoidoscopy the typical changes of colitis with ulceration. *Proteus morganii* was isolated from the stools on culture.

Full courses of penicillin and "sulphasuxidine" together with sedatives, low-residue diet, etc., failed to influence the condition over the next two weeks. Local treatment with a tannic-acid solution was reluctantly tried, still without any improvement.

In view of its reputation with Gram-negative organisms it was then decided to try the effect of streptomycin. For seven days the patient received 0.5 g. thrice daily intramuscularly, together with 0.5 g. in 8 oz. (230 ml.) normal saline per rectum daily. On the third day the temperature settled and the number of stools diminished rapidly, and on the ninth day from the installation of streptomycin therapy she passed one normal stool free from blood, pus, and mucus, and culture was negative. At this stage and for the next three weeks transfusions of a half-pint (570 ml.) of blood were given twice weekly to combat a moderately severe secondary anaemia.

Having remained well for four weeks, the patient's temperature rose to 101° F. (38.3° C.), and on the following day she passed ten stools containing blood and mucus. Streptomycin was immediately administered on similar lines as before, and on the third day the condition cleared quite suddenly. This time a total of 8 g. was given. Stool culture at the beginning of relapse was negative.

The patient's progress from now on was an uninterrupted recovery; and prior to discharge, after hospital treatment for 16 weeks, sigmoidoscopy revealed a normal rectum and sigmoid colon, though the radiological picture was substantially unchanged. She has remained well and free from symptoms since, a period of ten months.

It is interesting to note that in this case there was a history of a severe attack of epidemic diarrhoea three years previously.

A psychological background was added by the birth, ten months after this attack, of a mentally defective (mongol) child, a factor which profoundly affected the patient's outlook since.

These points are interesting in view of the diverse views of the aetiology of ulcerative colitis. Perhaps there is a little of truth in both the psychosomatic and infective schools of thought, and more often than we have realized the colon may have been the recipient of both types of trauma. Intestinal infection and psychosomatic stress are both common, and thus the comparative rarity of ulcerative colitis may be explained by the necessity for coincidence.

In conclusion, may I suggest that cases such as the above and Dr. Frankel's indicate that absolute and dogmatic statements regarding the use of streptomycin in ulcerative colitis may yet prove premature. The danger of such an attitude towards comparatively new forms of therapy has recently been rather forcibly demonstrated in Ireland, where streptomycin has been controlled on the advice of the Medical Research Council, and gastro-intestinal infections are not even mentioned in the schedule of diseases in which permission to use the drug will be granted.—I am, etc.,

Dublin WILLIAM F. O'DWYER

An Unusual Murmur

SIR,—The unusual murmur described by Dr. F. A. Ward (December 10, p. 1353) with the accompanying case history suggests the diagnosis of a small spontaneous pneumothorax. I myself suffered from recurrent spontaneous pneumothoraces a few years ago, and during an attack I often heard and felt the clicks described by Dr. Ward (known in the textbooks as aortic or systolic clicks).

My own personal experience indicates that the systolic clicks are influenced by posture and to a lesser extent by respiration. With alteration of posture, often very slight, they could be made to appear or disappear at will. This probably accounts for the sudden disappearance and reappearance of the clicks in Dr. Ward's case. It was also my experience that the clicks are more pronounced the smaller the pneumothorax.

It seems probable, therefore, that in Dr. Ward's case there was present a small pneumothorax, possibly localized by adhesions, which did not show up on the radiographs.—I am, etc.,

Ryton-on-Tyne, Co. Durham P. H. DICKINSON

Splenic Puncture

SIR,—I was particularly interested in Dr. Emanuel Tuckman's reference (November 12, p. 1112) to the increasing employment of splenic puncture as a diagnostic measure in blood diseases. Thirteen years ago, in describing the technique of this puncture, I wrote[1]:

"In the investigation of the pathological processes in blood and other diseases in which splenic enlargement is a prominent symptom, the possibilities of spleen puncture have not been fully explored . . . and it seems certain that useful information regarding the processes of blood-cell destruction might be obtained from the blood taken directly from the sinusoidal spaces in the spleen."

I am in entire agreement with Dr. Tuckman's statements on both the relative safety of splenic puncture and on its greater value in the diagnosis of kala-azar. I also agree that the safety of the operation depends to a great extent on the speed with which it is done. However, I was not impressed with his technique for spleen puncture. I have no doubt that it is much simpler than it sounds. I wonder whether Dr. Tuckman has tried the method described in the paper referred to above. This certainly needs a special syringe attachment, but it is one that can be made very easily by any local tinker. This attachment gives the operator complete control of the syringe with one hand and leaves the other hand free to grasp the spleen.

I could not quite see why Dr. Tuckman claimed that his method made one independent of the patient's co-operation. With my attachment, however, it is possible to do a spleen puncture on a screaming struggling child: all the help that is needed is for someone to keep the child's hands off the syringe With a firm grasp of his spleen one is quite indifferent to the child's gyrations around this central point. The needle is in the spleen for only a fraction of a second, so that danger of damage to the capsule is reduced to a minimum.

I have used this syringe attachment for twenty-odd years in over 6,000 splenic punctures in kala-azar and in a variety of blood diseases, without fatalities or any serious ill effects and I now do not care to do the operation without it. If it is true that splenic puncture is becoming more popular among haematologists, I would draw their attention to this simple attachment.—I am, etc.,

Hyaluronidase and Bee-sting Sensitivity

SIR,—In reply to the letter by Drs. W. R. S. Panckridge and C. Q. Henriques on the subject of angioneurotic oedema caused by a wasp-sting (December 10, p. 1354), I wish to make the following comment arising out of observations on two cases of bee-sting sensitivity.

The exquisite degree of sensitivity seen in cases of bee-sting is evident from the severe and on occasion fatal reactions recorded in the literature and in the press. There is evidence that this sensitivity is of an allergic character and is based on sensitization following previous bee-stings. The rapidity of development and widespread severity of the reaction are of the highest order. Among the ordinarily encountered parallels is that seen in cases receiving pollen-hyposensitization therapy, and even here the reaction is rarely as acute or as severe.

The likeliest mechanism for these severe reactions may be (1) a very high degree of sensitivity, as seen by the vigorous skin reactions obtained with testing, or (2) the possibility of accidental intravenous administration of the allergen. The latter is unlikely, though possible even in the case of bee-stings The fact that bee venom contains hyaluronidase suggests an alternative mechanism. The hyaluronidase could facilitate the rapid and massive absorption of the antigen and could therefore account for the acute and severe generalized reaction.

The two cases of bee-sting sensitivity which were investigated and treated were two members of the South African police force. Their histories varied only in degree. In the one case there were two incidents of almost immediate unconsciousness lasting up to 1½ hours, followed by severe generalized oedema and respiratory distress. The second case, while not so severe, was prostrated with extensive angioneurotic oedema and severe abdominal pains.

Scratch tests were carried out with (1) a bee-venom extract prepared commercially for the treatment of rheumatoid arthritis; (2) bee body protein extracted with carbol saline after the sting and venom had been carefully removed; (3) a drop of honey placed on the skin. The more severe case gave strong positive reactions with all three test materials, while the other did not react to being scratched through the honey. The antigen, therefore, is contained in the bee protein, not solely in the venom. This observation has been confirmed previously by other workers. Both patients responded well clinically to hyposensitization with a bee protein extract prepared by the South African Institute for Medical Research. The response was assessed by the increasing tolerance of the skin to larger doses of the injection material. As emergency measures, the patients were instructed to carry with them a syringe, adrenaline for injection, tablets of ephedrine and of "benadryl" (oral adrenaline, such as "neo-epinine," would appear to hold out the advantages of easier application and portability). When last seen neither had been exposed to the crucial test of being stung again, though it is reasonable to expect that benefit may have accrued from the treatment.

It is suggested, therefore, that the anaphylactic-like response to bee-sting is due to (1) a high degree of sensitivity to bee protein following on previous sensitization, and (2) the adiuvant effect of hyaluronidase in the bee venom; this could facilitate and make more complete the rapid absorption of the antigen.—I am, etc.,

London, W.C.1. J. PEPYS.

Librarians in Children's Wards

SIR,—At a recent conference on "The Librarian in the Children's Ward" held by the Guild of Hospital Librarians on November 9 the audience was surprised to learn that at several hospitals, including large and well-known establishments, librarians were not allowed into the children's wards at all. The opposition, so far as we could gather, comes mainly from the nursing staff, and the reason given is usually "infection." It is not clear whether the librarian or her books are held to be the conveyers of disease, but in any case we respectfully take leave to doubt whether the objection is a reasonable one. If it were valid it would surely be applicable to all children's wards, which is not found to be the case. Where the librarian is welcomed, difficulties about infection traceable to her presence or to the distribution of books do not arise in practice.

It also emerged at the conference that where the teacher acts as children's librarian the books are sometimes locked up at the beginning of the school holidays and the children are deprived of this solace just when they need it most. A few old books left for the nurses to distribute do not in the least meet their wants.

Do these defects in hospital library service really matter? The attention now being paid to the psychological effect of hospital admission on children has shown how bored and frightened and home-sick they can be behind a mask of docility. It seems strange that the best and cheapest means of comfort, occupation, and mental stimulation—a good supply of suitable books—is still not being fully utilized.—We are, etc.,

JOHN FOSDYKE, President.
LETITIA FAIRFIELD, Chairman.
JOAN CLOKE, Secretary.
Guild of Hospital Librarians.

London, S.W.3.

POINTS FROM LETTERS

Health and the Soil

Dr. A. D. WILLIS (Guildford) writes: The letter by Dr. G. T. Wrench (November 19, p. 1178) has stimulated no discussion, yet it is surely of vital importance. It is not widely realized that there is a direct relationship between human health and soil fertility, a capital asset which has been squandered throughout the world with a prodigal disregard for its consequences. The lost fertility can only be restored by a return to organic cultivation. . . . Lack of humus in the soil not only deprives plants of their natural food but changes the character of the soil and encourages erosion. By such methods and the wholesale slaughter of tree and hedgerow America leads the world in the creation of deserts; but there are signs that erosion has begun in England, particularly in East Anglia. Diseases and pests affecting plants have been well named by the late Sir Albert Howard as "nature's censors," since they do not attack the healthy plant to any significant extent. It is known that health in plants depends on following nature's law of return and also that animals feeding on such plants enjoy the same vigour and immunity from disease. . . . The time is, surely, appropriate to initiate a series of experiments embodying these principles and practices to test their validity in a scientific manner.

Dr. K. O. A. VICKERY (New Malden, Surrey) writes: Dr. G. T. Wrench's timely reminder of our neglect of the soil and our continued preoccupation with disease (November 19, p. 1178) must not pass unheeded. It is hardly suprising that there is no mention of the soil in the National Health Service, while we of the profession continue to pay such scant attention to the vital interdependence of soil, animal, and human health. . . .

Painful Experiments

Mr. J. L. DOBBIE (Manchester) writes: I am glad you found room to print at least one protest (December 10, p. 1356) under this heading. The question is whether we are capable of moving with the contemporary current of civilization. Such a question deserves more attention, and ought not to be bedevilled by the conflicting passions of vivisectors and their enemies.

Small Mothers and Large Babies

Dr. P. STACK (Worksop, Notts) writes: A primipara whose height is 4 ft. 10½ in. (168 cm.) was delivered with forceps of a living child weighing 10 lb. 7 oz. (4.73 kg.). . . .

Obituary

T. A. HINDMARSH, M.S., F.R.C.S

Mr. Thomas Albert Hindmarsh, of Newcastle-upon-Tyne, died on December 8 in Newcastle Infirmary at the comparatively early age of 60. "T. A.," as he was affectionately known among his colleagues, always intended to be a surgeon. It was to further that end that he took the Conjoint diploma in 1913 after graduating M.B., B.S at the University of Durham in 1911. The varied house appointments which he held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, in the medical, gynaecological, and dermatological wards, apart from his period as house-surgeon, served as a further preparation. Though it may have been without design, a short assistantship in a country practice followed by a partnership in a practice in Cumberland helped to make him a "good doctor" and contributed in after years to his successful handling of patients and his equally successful relationship with practitioners. In the 1914–18 war he served in the R.A.M.C. overseas, mostly in Salonika, and there he came in contact with many surgeons whose practice and outlook he analysed with discernment as a guide to his own future conduct.

Back in England it was not long before he was appointed a surgical registrar in his old hospital at Newcastle-upon-Tyne—a wonderful training school with a wealth of clinical material. During 1919 he took with first-class honours the M.S. of his own university, and in the same year the F.R.C.S. He was made assistant surgeon three years later and a full surgeon in 1935, and from then onwards he continued to serve the Royal Victoria Infirmary loyally and devotedly. In his short final illness his one desire was to get well enough to resume the work that he loved.

Hindmarsh was always a general surgeon with an aptitude for dipping into new fields. His craftsmanship was easy and effective, and in most cases produced a great measure of success. It was just that success and a certain emulation of the pioneer work of Sir Thomas Dunhill that attracted him to the surgery of toxic goitre, in which he eventually acquired an enormous experience and outstanding success. It was not only his care and skilful technique that brought these rewards, but a nice understanding of the problems of each individual case, an understanding and unremitting care which in the earlier days had to be sustained throughout the management of many critical cases His optimistic approach to each problem was undoubtedly a great help, not only to his patients but to the nurses and those about him. Hindmarsh was a very successful abdominal surgeon, as so many of his friends and colleagues can testify from personal experience; he had long been a "doctors' surgeon." In this field of surgery he recognized few limitations and did most things well. His thorough grounding in principles undoubtedly helped him, and he was never appalled by impending or unexpected difficulties. In recent years he had been especially interested in the surgery of the sympathetic nervous system.

Though he never paraded his knowledge of surgical literature, Hindmarsh somehow was always up to date. He loved to travel, and was an acceptable and popular member of more than one surgical club. On visits to foreign clinics he showed himself a discerning observer and judge of men. Hindmarsh was not ambitious. His daily work filled his life and he wrote but little. His teaching was neither didactic nor systematic, but he had great influence among the students, who learned much from his informal

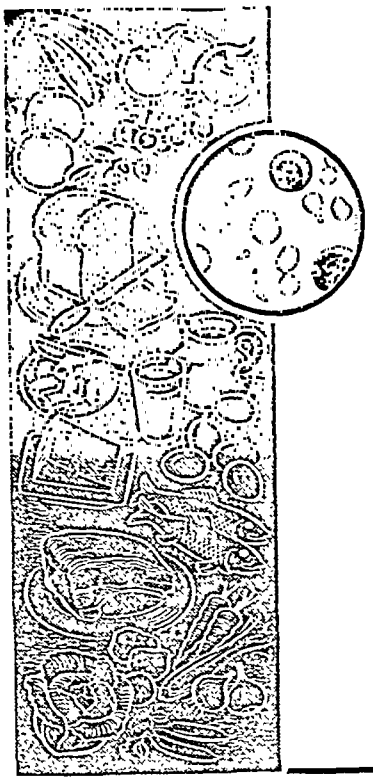
talks. It gave him pleasure recently when he was elected an examiner for the final Fellowship, and he was eagerly looking forward to his duties in this connexion. For years Hindmarsh had conducted a very large and widespread consulting practice, and in addition to his main work in Newcastle he operated regularly in outlying hospitals twenty to forty miles distant. In these areas his name was well known to doctors and patients alike.

"T. A." was a most loyable man, and he will be sadly missed in Newcastle. He had a warm, genial, kindly disposition and radiated good cheer. He loved to hear or to tell a good story. Although he worked so hard he found time to pursue his hobbies. He was a good golfer, a keen fisherman, and interested in music. He was happily married, and he leaves a widow and two daughters, to whom the sincere sympathy of all his colleagues and friends will be extended.—J. H. B.

A. J. HIRD, M.B., M.R.C.P.

Dr. Alan J. Hird, a junior lecturer in medicine at the University of Glasgow, was killed early on December 11 when he fell several hundred feet while undertaking an overnight climb of Am Bodach, a mountain near Kinlochleven. Dr. Hird was a member of the Scottish Mountaineering Club and a keen and experienced climber. His career, cut short at the age of 32 by this tragic accident, was one of great promise.

Alan James Hird was the son of the late Mr. James Hird, principal teacher of chemistry at Allan Glen's School, Glasgow. Educated at Glasgow Academy, of which he was dux at the age of 16, he entered Glasgow University and took a B.Sc. in 1937. He went on to graduate M.B., Ch.B. with honours in 1940. He then held resident posts as house-physician at the Western Infirmary, Glasgow, and house-surgeon at the Royal Hospital for Sick Children, before joining the Navy as a surgeon lieutenant. After completing his service Hird took the M.R.C.P. in 1947. He was then appointed medical registrar at the Southern General Hospital, Glasgow, and shortly afterwards was made a junior lecturer in medicine at the University, in the department of the Regius Professor of Medicine at the Gardiner Institute and Western Infirmary. Alan Hird was particularly interested in research on diseases of the blood, and he had already published a number of useful contributions. In the past year he had often been of much assistance to the *Journal* in writing annotations and occasional leading articles.



Hird was greatly liked by all his colleagues for his charming manner and for the firmness and resolution which he showed in his approach to any problem, whether in the clinical or research field. He was the only child of his widowed mother, and to her the sympathy of all his friends and colleagues will be extended.

Professor J. W. McNee writes: The tragic death of Dr. Alan Hird at the age of 32 in a mountaineering accident is a severe blow, both to Glasgow University and to the Western Infirmary. Hird was universally recognized among his colleagues, old and young, to be on the way towards a brilliant career in medicine, and his aptitude for independent research work was apparent to all. He was just in course of applying for one of the coveted Commonwealth Fund Fellowships, and if successful would have spent the next year or two at either Harvard or Rochester University in the United States on exciting research work, which he had already tentatively planned. Hird was a fine lad and greatly liked by all his colleagues. There is no doubt that a fine young physician, steadfastly moving towards the light, has been lost by the Glasgow School of Medicine.

Dr. EDWARD EDELSTEN BRIERLEY died suddenly in Ramsey, Isle of Man, on December 8 at the age of 78. His family came from the Rochdale area. He was proud of being a Haileybury man, and he graduated M.B., C.M. at Edinburgh in 1895. Five years later he took the F.R.C.S.Ed., and this was to affect some of the later phases of his career. He held some resident appointments and undertook a trip to the Far East before settling in practice in Cardiff in 1901. His practice developed rapidly and included some surgery, though he was narrowly unsuccessful in his application for a surgical post on the staff of the Cardiff Royal Infirmary. He found partnership helpful, notably that with Dr. Telford Morgan, who now carries on the practice. Brierley was a keen B.M.A. man, and filled many of the important Association offices locally as well as representing the Cardiff Division at the Representative Meeting almost without a break from 1915 to 1933. He was president of the South Wales and Monmouthshire Branch in 1931–2 and chairman of the Cardiff Division. He also served for ten years on the Charities Committee of the Association. His contributions to professional and medico-political discussions in Divisional and Branch meetings were able and interesting. Many will recall that when the Association was aroused by the advent of the Insurance Act his observations, while intensely critical, nevertheless conveyed a sense of the inevitability of some such development. Brierley was an ardent churchman, and for many years he was vicar's warden at the Church of St. John the Baptist, Cardiff. After 33 years in Cardiff it became necessary for family reasons that he should move to the Isle of Man. At Ramsey, from 1934 onwards, Brierley developed a moderate practice and at the same time, as was his custom, took up his interests in the Church and in medical politics. He became vicar's warden at the Church of St. Olave's, Ramsey. He was president of the Isle of Man Division of the B.M.A. from 1939 to 1943, and president also of the Isle of Man Medical Society. He worked, too, for the Red Cross Society, and with that body rendered sterling service during the war. He was an expert pigeon fancier, and it was just two days before his death that the award of a first prize to one of his exhibits was announced. Brierley was a man and a colleague whom it was a privilege to know. He was as upright in conduct as in figure. A very wide circle of friends will feel the utmost sympathy with those whom he leaves—his widow, whose devotion and expert knowledge of medical matters must have been of the greatest service, one daughter, and three sons, one of whom is in practice.—E. J. M

Dr. FRANK THORNTON BIRKINSHAW died suddenly at his home in Auckland, New Zealand, on October 2, 1949, at the age of 50 years. Born at Ovingham-on-Tyne in 1899, Dr. Birkinshaw was educated at the King Edward School, Birmingham, and at Birmingham and London Universities. He joined the Royal Warwickshire Regiment during the first world war and was later attached to the Royal Air Force, in which he saw service with a special duty flight attached to the Hedjaz army. He was for a time the personal pilot of T. E. Lawrence, and was decorated by the French and British Governments. After the armistice he returned to his regiment and later joined the Royal Army Medical Corps. He went to New Zealand in 1930, and practised in Amberley and Christchurch, where he was a vice-president of the Returned Services Association. Dr. Birkinshaw came to London in 1937 for postgraduate study. After 18 months he returned to Christchurch and in 1940 was appointed medical superintendent of the Coromandel Hospital. He relinquished this appointment in 1943 to commence practice in Auckland as a consultant physician. Dr. Birkinshaw is survived by his wife, Dr. Edna Birkinshaw, and by one son and one daughter.

Dr. WILLIAM SCOTT HALL, who died on November 14 at the age of 74, was for many years one of the best-known medical practitioners in Scunthorpe. Dr. Hall was a student at Marechal College, Aberdeen, and at the Middlesex Hospital, graduating M.B., Ch.B. in 1897. He came to North Lincolnshire as an assistant in practice at Althorpe before settling in Scunthorpe. Then in 1902 Dr. Hall went into partnership in Bradford, returning to Scunthorpe again after four years as a captain in the R.A.M.C. during the 1914–18 war. He retired from practice

The combination of folic acid and ferrous iron in FOLVRON presents in a single product two nutritional fundamentals — a specific for red-cell maturation and a stimulant of haemoglobin formation.

FUNDAMENTALS IN NUTRITION— FOLIC ACID AND IRON

An ideal dietary reinforcement in convalescence, malnutrition, and many deficiency diseases, FOLVRON also provides a valuable supplement in both macrocytic and iron-deficiency anaemias.

Capsules or tablets containing folic acid 1.7 mg. and ferrous sulph. exsicc. 3 grs.

BRETTENHAM HOUSE, LANCASTER PLACE, LONDON, W.C.2.

In a report of 146 cases it was found that sacro-iliac sprain "is the major cause of low back pain." Treatment included "in severe and chronic cases a suitable sacro-iliac belt as protection."*

Spencer Sacro-iliac Support especially designed for this man. A pelvic binder of non-elastic webbing (see inset) encircles the pelvic girdle *inside* the support. Easily adjustable from *outside* the support to degree of control required.

For the relief of Sacro-iliac pain prescribe SPENCER

The reason why Spencer Supports are therapeutically effective is: each Spencer is *individually designed, cut, and made* at our Manufactory in Banbury—after a description of the patient's body and posture has been recorded and detailed measurements taken.

This assures the doctor that each patient will receive the proper design to aid his treatment; that the support will fit with precision and comfort.

* *Treatment of Sacro-iliac Sprain by Manipulation, Jr. Fla. Med. Assn.*, 33: 193–196 (Oct.), 1946.

LAWS OF MEDICINE

Flint's Law

"The ontogeny of an organ is the phylogeny of its blood supply"

AUSTIN FLINT, JN

AUSTIN FLINT, Jn. (1836-1915) *was an American physiologist. In 1874 he published a treatise on physiology in which his law appeared.*

Ontogeny repeats phylogeny in modern drug manufacture as well as in nature.

The stages in the synthesis of a new compound often recapitulate the stages in the development of the chemical family to which that compound belongs.

The files of Boots research organisation carry records of thousands of experiments made in the search for new remedies. These carefully compiled records form almost a race history of compounds synthesised in the service of the medical profession.

'ROCHE'

ANTIHISTAMINE

Different in chemical structure from other antihistamine drugs now available

'THEPHORIN'

'Thephorin' is distinctive also in its properties: in the great majority of cases it is well tolerated and it very rarely produces drowsiness. 'Thephorin' can therefore be given during the day without inconvenience to the patient.

NO DROWSINESS

Tablets of 25 mg. in bottles of 50, 250 and 1000. Also 5 per cent ointment in tubes of 1 oz.

Samples and literature are obtainable from the Medical Information Department

HYPON TABLETS

A BALANCED FORMULA PLUS.

caffein and phenolphthalein

In cases requiring continuous administration of Codein compounds the general practitioner is often concerned by the SIDE EFFECTS of INTESTINAL STASIS and MENTAL DEPRESSION.

The inclusion of a fractional dose of Phenolphthalein ensures that the normal function of the alimentary tract remains undisturbed, whilst the stimulating effect of Caffein counteracts depressive tendencies associated with Codein and Acetylsalicylic medication.

HYPON TABLETS can be prescribed with confidence in all cases where an analgesic or antipyretic is indicated.

FORMULA: Acid. Acetylsalicyl. 40.22%. Phenacet. 48.00%. Caffein 2.00%. Codein Phosph. B.P. 0.99%. Phenolphthal. 1.04%. Excip. 7.75%. (Each tablet 8 grains.)

Samples gladly sent on request.

WRITE TO
CALMIC LIMITED CREWE HALL CREWE

only three years ago, and lived in the Isle of Axholme and subsequently at Epworth. Dr. Hall was a man of few words, sometimes difficult to approach, sometimes brusque and gruff in manner. These outward garments served only to hide a man of deep feeling and compassion, a doctor to whom the ills and distress of his patients were of real moment, distressing to himself. He had an independent outlook on medical problems, but he kept pace with the rapid advances in medicine, and his younger colleagues could always rely on a sound, modern, balanced, pithy comment on any subject under discussion. His practice extended far and wide in North Lindsey, his many patients relying on him to continue to serve them even at great distances. As a magistrate his deep insight into human behaviour was always of value to colleagues on the bench, where he joined his own sense of personal integrity with a sympathetic understanding of human failings. His interest in things other than medicine was wide. He had pronounced views on the failings of our social order, and could speak vehemently at times of need for change. His great hobby was the collection of old prints and etchings, about which he had something of a connoisseur's knowledge. His widow and two sons and two daughters survive him.—J. R. B. and W. H. B.

Dr. ALFRED ERNEST REMMETT WEAVER, who died on November 15, was formerly medical officer of health for Weston-super-Mare. A student at Birmingham University, he graduated M.B., Ch.B. in 1904, proceeding M.D. two years later and taking the D.P.H. in 1908. He entered the public health service in 1906, and was for more than 20 years deputy to Sir William Savage, who was then county medical officer of health for Somerset. Then in 1929 Dr. Remmett Weaver succeeded the late Dr. John Wallace as medical officer of health for Weston-super-Mare. He continued in this appointment until his retirement in August, 1941. He acted also as superintendent of the isolation hospital, and he was responsible for creating an up-to-date maternity and child-welfare service for Weston. In his retirement Dr. Remmett Weaver continued to play an active part in local affairs. He did a great deal of work for St. Paul's Church, where he was churchwarden, and recently represented the church at the Locking Ruri-decanal Conference. He was a past president of the local Rotary Club, and took a keen interest in the Somerset Association for Mental Welfare and in the local Tuberculosis Care Committee.

Dr. WILLIAM HILTON PARRY died suddenly at his home in Caernarvon on November 19. A son of the late Dr. Robert Parry, he was born in Caernarvon and educated at Llandovery College, the University College of Wales, Aberystwyth, and Liverpool University. He graduated M.B., Ch.B. in 1911, and was house-surgeon and subsequently house-physician at the Royal Southern Hospital, Liverpool. In September, 1914, he was posted to the 14th General Hospital at Wimereux, and a year later he transferred to the No. 3 Field Ambulance of the 1st Division. He then served as medical officer of the 4th Battalion, Grenadier Guards, and later was with the 3rd Guards Brigade in the Battle of the Somme and was twice mentioned in dispatches. For his work during the Passchendaele attack he was granted an immediate award of the M.C. At the end of 1917 he was graded unfit for further service abroad and appointed surgeon specialist at the Alder Hey Military Hospital. A few months later, however, he managed to get back to France, where he served with distinction while attached to the Australian Division. On demobilization Dr. Hilton Parry joined his father in general practice in Caernarvon. Shortly afterwards he was appointed medical superintendent to the Gallt-y-sil Isolation Hospital, and he later became superintendent of the Eryri Hospital and Bodfan Mental Home, medical officer of the port sanitary authority, and police surgeon. He had been a borough magistrate since 1930, and for many years was a member of the local panel committee, serving as its chairman for a time. He was made chairman of the North Caernarvon and Anglesey Division in 1928–9, and was president of the North Wales Branch in 1945–7. During the recent war Dr. Hilton Parry served as chairman of the local medical board. He also acted as medical officer of a Caernarvonshire Home Guard battalion, and was later promoted to zone medical officer for Caernarvonshire with the rank of lieutenant-colonel. In 1945 he was accorded the honour of nomination as high sheriff of Caernarvonshire. In recent years Dr. Hilton Parry had been a member of the local executive council and of the local medical committee for the area. In his youth Dr. Hilton Parry was an enthusiastic athlete, and at the age of 17 he swam the Menai Straits at their widest point. He was a keen footballer and cricketer and also a useful boxer. He leaves a widow, one son, and one daughter. His elder daughter was killed in a London hospital, where she was nursing, during a flying-bomb attack in July, 1945.

A colleague writes: As a surgeon Dr. Hilton Parry was cool, resourceful, and undaunted by unexpected difficulties. He was at his best in operating on the many and varied acute abdominal conditions that he was called on to treat. A pupil of the Liverpool School, he was adroit in handling fractures, and he also had a long run of successful caesarean sections in the days before the modern maternity centres were available in the district. On a holiday outing his greatest pleasure was to bring along one or more of his friends to accompany him. Many of us have happy memories of summer afternoons in his boat in Caernarvon Bay, or trawling in the Menai Straits in the winter On such occasions he was a genial and generous host.

Lieut.-Colonel Sir Goronwy Owen, D.S.O., writes: By the death of Dr. W. Hilton Parry the town and county of Caernarvon have lost a much loved and highly respected figure. He had had a distinguished career, not only as a medical practitioner in civilian life for a period of 30 years, but also as a medical officer on active service in the first world war. His unfailing cheerfulness and his optimism endeared him to his patients in all ranks of life, and his indomitable courage in the face of his own agonizing illness placed him in a category of his own. His interests were not confined to his profession, but embraced many other activities and hobbies. He discharged his duties as a magistrate and as chairman of the advisory committee with the same punctiliousness and conscientiousness that he devoted to his profession, and not the least of his activities was his devotion to the Sea Cadets. He was also a keen photographer and yachtsman. In truth, he was a man of sterling character and of many parts.

Dr. FRANK HUSBAND-CLUTTON died on November 19 at his home in Crowland, Peterborough, at the age of 78. Dr. Husband-Clutton, who had been in failing health for two years, was well known in Crowland, where he had lived for 53 years. A student of Bristol University and Guy's Hospital, he qualified in 1894, and went on a voyage to India as a ship surgeon before settling at Crowland in 1896. Over the next 34 years, until his retirement in 1930, he was medical officer and public vaccinator for the Crowland district of the Peterborough Union. He was also medical officer for the Crowland rural council. While in practice and afterwards Dr. Husband-Clutton took a great interest in the work of the British Medical Association, and he was chairman of the Holland Division of the B.M.A. in 1924–5. It was after he retired that he became most active in local affairs. He served on the Spalding Council for many years, on the Holland County Council, and had been a magistrate since 1933. He is survived by his widow and a son and a daughter, to whom the sympathy of all his many friends will be extended.

Dr. ROBERT FRANCIS GERRARD died at his home in Great Sutton, Cheshire, on November 19 at the age of 74. A Lancashire man, he was educated at the Collegiate School, Chester, and at Liverpool University. He qualified in 1906, and after holding several assistantships in Lancashire settled down in Ellesmere Port, where he practised until a little over a year before his death. He was one of the early pioneers in the establishment of the district hospital, and was for many years chairman of the medical board. He was chairman of the Ellesmere Port Nursing Association for a long period, and he was police surgeon and a factory surgeon for many years. He was also a lecturer to the St. John Ambulance Association and did much to establish the association on a firm basis in

Ellesmere Port. Before the outbreak of the 1914–18 war Dr. Gerrard was prominently associated with the Cheshire Yeomanry, of which he was at one time medical officer. While serving in the Near East in 1916, attached to the Welsh Border Mounted Brigade Field Ambulance (74th Division), he was mentioned in dispatches. Dr. Gerrard always had the interests of Ellesmere Port at heart and was elected to the council in 1930, becoming chairman in 1933–4. He will be best remembered, however, by his colleagues in Birkenhead and Wirral as an active member of the B.M.A. He represented his constituency at the Annual Representative Meeting in 1946, and he was chairman of the Birkenhead and Wirral Division during the difficult period 1946–7. He was a fine family doctor, and his widow and two daughters, both of whom are members of the profession, will have the sympathy of his many friends, patients, and colleagues.—R. W. L. P.

Dr. THOMAS HUGH ROBINSON MCKIERNAN died at his home in Falmouth on November 21 at the age of 56. He was the fourth son of T. C. McKiernan, of Dublin, and was educated there at Mountjoy School and later Trinity College. On the outbreak of war in 1914 he interrupted his studies and at once volunteered as a surgeon-probationer R.N. After a period of service he was sent back to complete his medical studies in 1918, and immediately afterwards he rejoined as a surgeon lieutenant. Following his demobilization he was resident surgeon at Dr. Steevens's Hospital, Dublin, and later went to New Zealand, where he was medical superintendent of the N. Wairoa Hospital. Returning to this country, he settled in Falmouth, and soon built up a large practice, mainly surgical, in Falmouth and the surrounding country. He was one of the last of the dwindling body of general-practitioner surgeons. Dr. McKiernan was a quiet and retiring man, in whom his patients had profound confidence. He lived for his work, and paid frequent visits to the surgical clinics of America and the Continent. The death in action of his only son in 1940 was a great blow, a tragedy from which he never fully recovered. He had been ill for some years, and, in spite of advice to the contrary, continued to work at high pressure. As he would have wished, his end came when he was still in harness. To his widow the deepest sympathy of his friends will be extended.—J. A. S.

Dr. JOHN GORDON GORDON-MUNN died on November 29 at his home in his native Scotland. He was aged 86 and was the son of a distinguished Edinburgh mathematician. He graduated M.B., C.M. at Edinburgh University in 1889, proceeded M.D. with first-class honours in 1896, and was later elected F.R.S.Ed. Dr. Gordon-Munn served as medical officer to the 1st Battalion of the Grenadier Guards in South Africa and gained the South African Medal with six clasps. Returning to this country, he started in psychiatric work at Cane Hill Mental Hospital in association with Rotherham, Pope, and Armstrong Jones. After his training there in this distinguished company he took over the Heigham Hall private mental hospital in Norwich, and soon built up a large consulting practice. He retired in 1920. His professional duties permitted him little leisure to participate in outside activities, but in 1914 he was appointed lord mayor of Norwich, and worked hard and enthusiastically at his new duties. When war was declared he did a great deal for the public safety and was especially proud of his achievement in raising at the request of the Army Council a new unit for the Regular Army—the Norfolk Divisional Engineers, 1,230 strong. Dr. Gordon-Munn was a sound psychiatrist, and he will be missed by many friends. A bachelor, he was a wonderful host in his own house.—J. A. S.

Dr. LESLIE ALFRED HUMPHREY died on December 1 at the age of 32. During his early years in Tunbridge Wells he grew up a kind, charming, and seemingly idle lad, and it was only towards the end of his time at Winchester that he began to show the breadth of interests and the intellectual qualities which endeared him to such a wide circle of friends. At Trinity College, Cambridge, he learned much about life and rather less than his tutor thought proper about natural science. On going down from Cambridge, he joined I.C.I., Ltd., as a trainee, but when his father offered to make it possible for him to take up medicine he grasped the opportunity. He went to University College Medical School at the beginning of the war, when it was evacuated to Leatherhead and subsequently Cardiff. After a hesitant start Humphrey adapted himself to student life, and in the combination of scientific discipline with personal contact and interest provided by a medical training he found the outlet for his energies which he had been seeking. None of his contemporaries are likely to forget his enthusiasm, enterprise, and personality. After qualifying in 1944 he went to the West Middlesex County Hospital, first as house-surgeon and then as house-physician. Although this was his first medical post, he started a diabetic clinic and trained himself to make the electrocardiographic reports for the whole hospital. Some of his colleagues will remember his plan to commission artists to paint friezes in the children's wards—a plan which might have been accepted in other circumstances than those of the war. It soon became clear to him that he would not obtain a fundamental understanding of disease solely by clinical work, and he determined to become a pathologist. This was not undertaken as an aim in itself, but with the idea that he should equip himself sufficiently to form part of a team which could study particularly psychosomatic disorders. In this he was influenced by the work of Sheldon. He was accepted as a trainee in the Emergency Pathological Service, and spent two years in the sector laboratory at Ashford County Hospital, where, as always, he made many friends. At the end of his training he was placed in charge of the laboratory at the Queen Alexandra Military Hospital, Millbank. He was due for demobilization at the end of this year, and had been offered a research post which would have given him his first real opportunity to test some of his ideas. In February, however, he developed an obscure illness which was later proved to be periarteritis nodosa. Although aware of his condition, and although blind for the last three months of his life, he never lost any of his charm or dignity. Rather did he grow in intellectual stature, so that persons who went to visit a very sick man found themselves talking with one who was at least an equal, and who had turned his illness into an opportunity for reflection. In 1946 he married Lorna Ince, who survives him with two children.

Medico-Legal

IDIOSYNCRASY TO WHOOPING-COUGH VACCINE

On November 30 an inquest was held in Hanley on the death from encephalopathy of an eight-months-old infant. According to a recent press report[1] death was apparently due to an idiosyncrasy to pertussis vaccine.

The father gave evidence that his son, one of twins, had been in good health up to Saturday, November 26, when he was taken to the Hanley Clinic to receive inoculations against diphtheria and whooping-cough. Both children were immunized in the morning and were taken home by their mother. At about 6 p.m. one child began to cry and make strange movements with his arm. A doctor was called and the baby was admitted to hospital at 1.30 a.m. on the Sunday morning. The infant died less than an hour after admission.

Dr. C. Giles said he had never seen such an unfortunate consequence of whooping-cough inoculation. He had little doubt that it was the whooping-cough vaccine and not the diphtheria vaccine that was responsible. So far as he knew this was the first case of its kind to be reported in this country, although several had been reported in the United States. There was nothing to show that the inoculation was not properly carried out, and a number of children had been inoculated with material from the same bottle of vaccine without ill effect. The vaccine was now being examined at the Central Public Health Laboratory in London.

The coroner, who returned a verdict in accordance with the medical evidence, told the father that he had been right in consenting to the immunization being performed. This case was "perhaps one in hundreds of thousands."

[1] *Hanley Evening Sentinel*, November 30, 1949.

Medical Notes in Parliament

On December 16, before Parliament was prorogued, the Royal Assent was signified to the National Health Service (Amendment) Act, the Criminal Justice (Scotland) Act, the Nurses (Scotland) Act, the Adoption of Children Act, and other Acts.

Medical Services in Malaya

Colonel STODDART-SCOTT on December 3 invited Mr. Shinwell to make a statement with regard to the medical services provided for British troops in the Malayan campaign, and to state what improvements could be expected in the immediate future.

Mr. SHINWELL in reply said the medical services in Malaya included an adequate number of Service hospitals and medical officers to maintain the normal health of the troops and to care for the sick and wounded. Difficulties, however, arose in securing the immediate surgical treatment of battle casualties. Since fighting was carried on by numerous small columns of troops which operated in difficult country and were frequently on the move, it was impracticable to provide surgical facilities for carrying out operations in the immediate vicinity of the fighting. Consequently it was necessary for casualties to be evacuated to the hospitals where surgical attention could be given.

There were three Service hospitals in Malaya District, which covered the mainland of Malaya, but there was only one Army surgeon. It had accordingly been necessary to utilize the services of civil surgeons. In Singapore island there were three Service hospitals and three Army surgeons. To meet the deficiencies of surgeons in the Army as a whole, arrangements had been made to engage immediately a number of civil surgeons for short-term contracts. Three had already accepted the terms and conditions of service. Subject to their being physically fit they would be sent to the Far East as soon as possible to complete the establishment in that theatre. The evacuation of casualties presented great difficulties in view of the nature of the country. Efforts had been made for a considerable time to devise a suitable means of air transport from the jungle to the nearest hospital. Various tests had been undertaken, and work was proceeding on the modification of three helicopters to make them suitable for this task. They should arrive in Malaya in April, 1950. In the meantime, the effects of delay before surgical treatment were being minimized so far as possible by the use of penicillin and other drugs.

Antihistamines and the Common Cold

On December 13 Mr. JOHN LEWIS drew attention to the claims recently made in the United States of America about the efficacy of antihistamine preparations for the treatment of the common cold.

Mr. HERBERT MORRISON said in reply that the claims to which Mr. Lewis referred were of great interest to the Medical Research Council workers studying the problem of the common cold at the Harvard Hospital, Salisbury. Unfortunately, a carefully controlled attempt, made last spring, to confirm the value of one of the drugs most commonly recommended in America failed to show that it had any dramatic effect. The experiment emphasized the need for great care in assessing the claims made for cold cures, in view of the extremely variable natural duration of colds without special treatment.

Principals and Assistants in Scotland.—Mr. RANKIN on December 13 invited the Secretary of State for Scotland to indicate the number of general practitioners acting as assistants under the National Health Service scheme, and the number who were principals. Mr. WOODBURN said that on October 1, 1949, the number of assistants in Scotland was approximately 250, and the number of principals was 2,411.

Mass Radiography in Scotland.—Over 300,000 examinations have been carried out by mass radiography in Scotland since 1944. In the last year for which figures are available, up to June 30, 1949, over 97,000 examinations were made, as a result of which 670 persons were found to have active tuberculosis

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part I (Surgery, Midwifery, and Gynaecology):* M. S. Aldridge, I. I. Bornstein, A. S. F. Butcher, D. Butcher, E. P. Cadbury, N. I. Cardno, J. S. W. Chambers, A. C. Chovil, E. H. Coats, J. E. Dalby, J. W. B. Dalgleish, T. D. W. Davies, H. de Glanville, B. O. L. Duke, D. S. Eastwood, J. G. Elliott, J. Fairgrieve, P. R. Gittins, B. M. Gray, K. W. Gray, K. E. Halnan, J. M. Hodson, G. Holden, T. M. Howell, P. G. A. Irvine, J. D. Jackson, F. E. Kirk, T. P. Kissack, J. F. Lees, C. R. Leeson, T. S. Leeson, D. W. Lemmon, J. P. Lester, R. J. Lunniss, J. P. Lythgoe, K. M. McFadyean, K. G. P. Mackenzie, E. Marley, K. R. Mason-Walshaw, B. J. Muir, A. D. Muirhead, M. J. D. Newman, R. H. Oram, E. M. Orton, G. B. R. Oswald, M. J. Peel, G. N. St. J. Penney, J. C. E. Peshall, S. T. Pickles, R. B. Prowse, D. R. Pugh, J. C. A. Raison, P. J. Randle, M. Rayne, J. N. Redfern, J. R. Rees, A. M. Richardson, C. R. Robinson, J. H. Ross, J. J. H. Rymer, G. E. Sayce, J. O. Seville, I. M. Simmonds, V. H. Smith, J. B. Spargo, D. R. Sweetnam, Mrs E. R. Taylor, J. C. Turner, A. G. Wallace, W. J. Wigfield, P. L. Williams.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees and licences were conferred on December 8:

M.D.—W. E. R. Hackett, F. J. C. Loughran, J. D. McKeever, Irene S. Orgel.

M.B., B.CH., B.A.O.—J. H. Ashmore, Evelyn Browne, Joan I. Buchanan, L. J. Clein, Margaret B. E. Ellis, E. G. England, R. C. Gray, R. ff. Jackson, Vyvyan I. K. Johnston, O. H. Killen, W. A. McGaw, E. B. McHugh, Sheilagh M. McHugh, W. D. McNaul, T. T. E. Michael, E. V. Page, Ruth M. Perrott, Gwendoline G. L. Poots, W. D. H. *Powell*, R. N. *Siberry*, B. A. *McC. Thompson*, F. A. Walkey.

LICENCE IN MEDICINE, SURGERY, AND OBSTETRIC SCIENCE.—B. J. O'Reilly.

UNIVERSITY OF LONDON

Antony Clifford Dornhorst, M.D., M.R.C.P., has been appointed to the University Readership in Medicine tenable at St. Thomas's Hospital Medical School from October 1, 1949.

William Howard Hughes, M.D., has been appointed to the University Readership in Bacteriology tenable at St. Mary's Hospital Medical School from October 1, 1949.

Jack Joseph, M.B., Ch.B., M.R.C.O.G., has been appointed to the University Readership in Anatomy tenable at Guy's Hospital Medical School from April 1, 1950.

Raleigh Barclay Lucas, M.D., M.R.C.P., has been appointed to the University Readership in Pathology tenable at the Royal Dental Hospital of London, School of Dental Surgery, from January 1, 1950.

The title of Reader in Pharmacology and Therapeutics in the University has been conferred on Cyril Arthur Keele, M.D., F.R.C.P., in respect of the post held by him at the Middlesex Hospital Medical School.

Professor F. R. Winton and Mr. P. H. Mitchiner have been appointed representatives of the University on the governing bodies of the Institute of Psychiatry and Reigate Grammar School, respectively.

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *King's College Hospital Medical School:* Dr. R. S. Lewis (Oto-rhino-laryngology); Dr. Mary J. Wilmers (Children's Diseases). *Middlesex Hospital Medical School:* Dr. J. A. Hobson (Mental Diseases); Mr. I. MacG. Jackson (Obstetrics and Gynaecology). *Royal Free Hospital School of Medicine:* Dr. Frances Gardner (Medicine); Dr. Gladys Hill (Obstetrics and Gynaecology); Mr. G. Qvist (Surgery). *St. Mary's Hospital Medical School:* Mr. A. G. Cross (Ophthalmology); Dr. L. H. Morris (Anaesthetics). *University College Hospital Medical School:* Mr. J. W. Schofield, M.R.C.S., L.R.C.P., F.D.S. (Dental Surgery). *Westminster Medical School:* Dr. G. Garmany (Mental Diseases). The following teachers have been granted probationary recognition for two years from October, 1949: *London Hospital Medical College:* Mr. A. M. Horsnell, M.R.C.S., L.R.C.P., L.D.S. (Dental Surgery). *Royal Free Hospital School of Medicine:* Dr. A. G. Stansfield (Pathology (Morbid Anatomy)).

The John Marshall Fellowship in Surgical Pathology, of the value of £700 a year, for two years in the first instance and tenable at University College Hospital Medical School, has been awarded to Benjamin Bethel Milstein, M.B., B.S., F.R.C.S.

The following candidates have been approved at the examinations indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—[1]E. Brenman, [1]W. Calder, [1]D. H. Clark, [1]J. A. Ewing, [1]Joan I. Hallinan, [1]J. Hönig, [1]S. Jacobson, [1]J. M. Macdonald, [1]J. H. McDougall, [1]D. F. Macgregor, [1]S. Mansvelt, [1]J. D. Morrissey, [1]C. Rose, [1]Lotte Rosenberg, [1]I. M. Shepherd, [1]M. Shuaib, [1]R. L. Sikes, [2]R. J. Stanley. The following have passed in Part A only: A. S. Clenaghan, K.-C. Dubé, O. Elgarem, L. H. Field, Mercy I. Heatley, J. C. S. Houston, B. J. Phillips, A. A. Robin, D. B. Stone, A. A. Valentine, H. de B. Warren, R. H. Wheeler.

[1]With Mental Diseases (Psychiatry) in Part B. [2]With Mental Deficiency in Part B.

UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

PATHOLOGY AND BACTERIOLOGY.—A. G. Alexander, S. I. Davies, A. R. Harris, S. E. Ll. Morris, G. J. Moses, S. J. S. Polwin, Elizabeth M. M. Price, Margaret Pugh, T. A. I. Rees, Esther H. Thomas.

MEDICINE.—Marjorie J. Adams, C. H. Burman, R. B. Davies, B. M. Frost Smith, J. I. Hopkins, H. B. Jenkins, Beryl H. Jones, Mair G. Lloyd, D. Phillips-Miles, H. M. N. Rees, R. M. Richards, C. P. Seager, D. G. H. Thomas, J. D. Thomas.

PHARMACOLOGY.—Vyvian J. Bennett, B. N. Davies, W. E. J. Horton, J. H. Naysmith, C. J. Revington, Joyce M. Smith, Glenna Thomas, M. S. I. Wilkinson, Isobel M. Young.

K. S. Ray has satisfied the examiners at the examination for the Tuberculous Diseases Diploma.

QUEEN'S UNIVERSITY, BELFAST

The following candidates have been approved at the examinations indicated:

M.D.—[1]T. J. Harrison, W. I. Forsythe, Maude Stevenson, F. R. Johnson.

M.B., B.CH.—[2]Mary F. Brown, [2]E. N. F. Browne, [2]H. M'W. Lyle, B. J. Beatty, Hester C. Blagden, J. Blundell, R. H. Bolton, Barbara J. Bunting, Ruth M. Burns, M. M'C. Burrows, L. J. Byrne, R. L. Carson, J. C. Clarke, J. M. Clarke, W. H. Cochrane, Joan S. Dales, A. D. Dickson, Abigail F. R. Dodd, D. M. Downing, S. D. Emerson, J. T. Fisher, Margaret L. Fisher, Agnes A. Flewett, V. R. Gardiner, J. D. Glover, J. G. Gray, I. H. Greer, Denise M. Hall, J. H. Harland, Louise M. E. Hogg, J. G. Hudson, L. J. Hurwitz, R. B. Irwin, H. F. Jackson, S. M. Johnston, Margery C. Jones, T. W. Leitch, J. M. B. Lenfesty, Elizabeth S. Lindsay-Rea, J. B. Lowry, Jean E. M'Gowan, H. D. M'Kee, J. C. M'Nulty, H. H. M'Cartney, S. A. Millen, Elizabeth M. J. Milligan, O. H. A. Mitchell, W. R. Moffatt, E. J. Mulholland, D. Murphy, J. R. Nelson, K. A. Nelson, K. G. Orr, R. A. Robinson, Olive M. Russell, W. E. B. Scott, R. W. Simpson, H. J. Sloan, J. H. Smith, Dorothy Stewart, R. C. Stewart, F. R. Stinson, H. P. Swan, Charlotte M'E. Taggart, Patricia A. Thomas, T. N. F. Todd, H. A. Wagner, M. J. Wauchob, N. W. F. Weir, Edith S. Wells, R. W. Whiteley, L. M Wolf, G. I. Young.

[1]With commendation. [2]With second-class honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on December 8 with Sir Cecil Wakeley, President, in the Chair, Sir Harry Platt was appointed Bradshaw Lecturer for 1950.

The following examiners were appointed for the Primary Fellowship examination to be held in Ceylon, India, and Pakistan: Sir Gordon Gordon-Taylor (Anatomy), Professor G. Hadfield (Pathology), and Professor A. St. G. Huggett (Physiology).

Sir James Paterson Ross was reappointed as the Representative of the College on the Council of the National Association for Mental Health.

Hunterian Professorships were awarded to Professor Milroy Paul (Ceylon) and Mr. R. T. Johnson (Manchester).

The following hospitals were recognized under the F.R.C.S. regulations:—*General Surgery:* Auckland, New Zealand—Cornwall Hospital, Green Lane Hospital, and Middlemore Hospital (while controlled by the Auckland Hospital Board); Sydney, N.S.W.—Royal North Shore Hospital (being a teaching hospital); Brisbane—Mater Misericordiae Hospital (for six months only); Hobart—Royal Hobart Hospital; Launceston—Launceston General Hospital. *Ophthalmology and Otolaryngology:* Derby—Derbyshire Royal Infirmary; Brisbane—Mater Misericordiae Hospital; Victoria—Victorian Eye and Ear Hospital.

DIPLOMAS

Diplomas of Fellowship were granted as follows: J. L. Reid G. D. Channell, J. C. Watts, I. A. Donaldson, R. Ramsay, B Fairburn, N. C. Rogers, F. S. Gorrill, F. A. Henley, S. Pillai, L. A Atkinson, R. C. Jack, D. O. Williams, J. S. Tomkinson, A. E Howarth, H. A. Ripman, D. A. Langley, M. G. Wilson, J. P Mitchell, D. L. Evans, M. P. Durham, J. W. Betts, F. T. Graves G. S. Ramsay, F. R. Sutton, D. A. T. Farrar, B. H. Hand, D. W Thomas, M. O. Carruthers, K. Chitty, B. V. Jones, R. W. Tudor V. S. Brookes, D. A. C. Reid, A. Brown, A. W. Nurick, I. P Todd, I. B. Smith, J. S. R. Golding, A. M. H. Bennett, N. J Blockey, A. G Dingley, P. N. Robson, J. F. Bolton Carter, M. C. T Reilly, C. Taylor, R. Iskander, M. A. Radwan, A. J. Clyne, W. W Davey, M. M. Nath, Marjorie A. Powys, S. A. Bond, J. N Appleton, W. M. Manchester, B. M. Omar, T. G. Barlow, R. D Condon, H. H. Gilbert, H. El S. Higazi, G. P. Ramayya, T. G Cameron, W. W. Hallwright, L. Bonnin, R. R. Dickson, P. H Greenwell, J. S. Guest, L. Jayasuriya, R. C. R. Loane, A. F. Murphy E. R. W. Thomson, A. J. Alldred, J. Block, P. W. Cotter, C Dundon, R. C. Evans, B. P. Flannery, F. E J. Gabel, A. J. Gunning G. F. T. W. Henson, T. P. Morley, R. Patuck, A. Roper, M. I Symonds, D. Ainslie, A. Clain, P. R. R. Clarke, C. P. de Fonseka J. Hewet, D. A. Macfarlane, A. B. Mackenzie, W. J. McLaren, I. W MacPhee, T. H. L. Rosser, C. L. Tucker, L. S. Walsh, J. A. Baird H. D. W. Black, A. F. Bromwich, M. F. Butler, J. F. Dark, N. C Davis, J. D. K. Dawes, W. R. Lang, W. A. Liddell, N. J. Shah D. B. Caro, D. H. Keller, D. N. Ross, A. G. Parks.

The following lectures will be delivered at the College (Lincoln's Inn Fields, London, W.C.) at 5 p.m. each day. January 3, Erasmus Wilson Demonstration by Mr. C. E. Shattock, "Tumours of the Kidney"; January 5, Otolaryngology lecture by Mr. Rainsford Mowlem, "Injuries of the Nose and Sinuses"; January 6, Erasmus Wilson Demonstration by Mr. C. E. Shattock, "Tumours of the Testicle"; January 11, Erasmus Wilson Demonstration by Mr L. W. Proger, "Recent Additions to the Museum"; January 12. Ophthalmology Lecture by Professor Arnold Sorsby, "Prospects in the Control of Genetic Disease"; January 17, Arris and Gale Lecture by Mr. F. Douglas Stephens, "The Diagnosis and Management of Hirschsprung's Disease"; January 18, Arris and Gale Lecture by Mr. D. F. Ellison Nash, "The Surgical Aspects of Renal Damage in Childhood: Assessment, Salvage, and Aftermath". January 19, Erasmus Wilson Demonstration by Dr. Magnus Haines "Tumours of the Ovary"; January 24, Erasmus Wilson Demonstration by Mr. L. W. Proger, "Recent Additions to the Museum." The lectures are open to those attending courses in the College and to all other medical practitioners, dental surgeons, and advanced students.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Mr. Terence Millin will deliver the Miss Weild Lecture in the Hall of the Faculty, 242, St. Vincent Street, Glasgow, on Wednesday January 11, 1950, at 5 p.m. His subject is: "Retropubic Surgery." Medical practitioners are invited to attend.

The Services

Surgeon Lieutenant-Commander E. J. S. Woolley, O.B.E R.N.V.R., has been awarded the R.N.V.R. Decoration.

Brigadier J. M. Macfie, C.B.E., *M.C.*, has been appointed Commandant and Director of Studies, Royal Army Medical College and has been granted the temporary rank of major-general.

The Efficiency Decoration of the Territorial Army has been conferred upon Major F. H. Blackburn, R.A.M.C., T.A.

The Efficiency Decoration and 1st Clasp of the Territorial Army has been conferred upon Lieutenant-Colonel A. G. Henderson and Major W. B. Evans, R.A.M.C., T.A.

The following have been mentioned in recognition of gallant and distinguished services in Malaya during the period January 1, 1949, to June 30, 1949: Colonel A. E. Campbell, late R.A.M.C.; Colonel (temporary) R. S. Dickie, Lieutenant-Colonel W. A. Y. Knight, and Captains G. B. Brown, A. C. Milne, and J. C. Walker, R.A.M.C.

In the Northern Ireland Parliament recently the Parliamentary Secretary to the Ministry of Health and Local Government said that special geriatric units had been established in Ballymena and at the Belfast City Hospital. There was accommodation at Ballymena for 130 and at Belfast City Hospital for about 300 cases.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 3. [No. 48

Figures of Principal Notifiable Diseases for ... sponding week last year, for: (a) England a ... London (administrative county). (c) Scotland ...

Figures of Births and Deaths, and of Deaths re... are for: (a) The 126 great towns in England and Wales ... (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Rate per 1,000 total births (including stillborn)			25					40		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

The number of notifications in the week ended December 10 were: poliomyelitis 124 (141), polio-encephalitis 10 (15). Figures for the previous week are shown in parentheses. The total of 134 notifications of poliomyelitis and polio-encephalitis together may be compared with 76 in the corresponding week of 1947 and 36 in 1948. In 1926 the corresponding figure was 43 and in 1938 it was 30.

Multiple cases were reported from the following counties London 15 (16), Bedford 2 (0), Buckingham 3 (2), Cambridge 3 (1), Chester 4 (2), Cumberland 3 (0), Devon 2 (0), Dorset 4 (1), Essex 10 (7), Gloucester 2 (7), Hertford 3 (2), Kent 8 (10), Lancaster 9 (14), Middlesex 6 (15), Norfolk 4 (4), Northampton 2 (1), Nottingham 3 (6), Southampton 2 (5), Stafford 3 (5), Surrey 6 (6), East Sussex 5 (4), Warwick 5 (6), East Yorks 2 (0), West Yorks 13 (19), Glamorgan 4 (6).

Discussion of Table

In *England and Wales* there were decreases in the notifications of scarlet fever 72, whooping-cough 54, diphtheria 31, and poliomyelitis 35; the only appreciable increase was in the incidence of measles 185.

The only changes of note in the notifications of measles were increases in Norfolk 144 and Durham 125. The total notifications in these two counties formed 56% of the total for the country as a whole.

The largest decreases in the incidence of scarlet fever were London 41 and Derbyshire 38; the largest increase was Middlesex 34. Notifications of diphtheria decreased in Lancashire 11 and London 7 and increased in Cheshire 5; the main centres of infection during the week were Birmingham C.B. 12, London 11, Birkenhead C.B. 8, and Liverpool C.B. 8.

The largest fluctuations in the local returns of whooping-cough were a rise of 34 in Yorkshire West Riding and a fall of 34 in Lancashire.

Notifications of dysentery during the week included Gloucestershire 30 (Bristol C.B. 9, Cheltenham R.D. 21); Lancashire 21 (Wigan C.B. 9); Cheshire 16 (Ellesmere Port U.D. 14); Yorkshire West Riding 16 (Leeds C.B. 5); Glamorganshire 16 (Cardiff C.B. 6, Cardiff R.D. 6); Durham 12 (Sunderland C.B. 5); London 10. The only large outbreak of food-poisoning notified was in Somerset, Wincanton R.D., where there were 60 cases.

In *Scotland* decreases were recorded in the notifications of acute primary pneumonia 84, scarlet fever 81, and measles 16, while the only increase of any size was whooping-cough 19. A decrease in the incidence of scarlet fever and pneumonia was noted in most areas of the country. Another 28 cases of dysentery were notified from the outbreak in Stirling county, where there were 10 cases in the preceding week; Glasgow had 49 notifications during the week.

In *Eire* the notifications of measles fell by 108 and of whooping-cough by 22. The fall in the incidence of measles was mainly due to the experience of Waterford, Waterford R.D. No. 1, where the notifications decreased from 108 to 16. An outbreak of 29 cases of measles was reported from Kilkenny. Callan R.D. A further 8 cases of typhoid were notified in Mayo, Claremorris R.D.

In *Northern Ireland* there were decreases in the notifications of scarlet fever 67 and whooping-cough 22. There was a rise of 29 in the incidence of measles.

Week Ending December 10

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,855, whooping-cough 893, diphtheria 87, measles 1,596, acute pneumonia 734, cerebrospinal fever 37, acute poliomyelitis 124, acute polio-encephalitis 10, dysentery 133, paratyphoid fever 5, typhoid fever 4, food-poisoning 95.

Medical News

Physician to the King's Household

Dr. R. Bodley Scott has been appointed Physician to the King's Household in succession to Dr. D. T. Davies, who has been appointed Physician to the King.

Nuffield Foundation Medical Fellowships

The Nuffield Foundation is offering a number of fellowships to enable selected persons to receive such higher training as will qualify them for senior appointments in medical teaching and research. All medically qualified persons are eligible to apply for them, but preference will be given to those who wish to specialize in the following: child health, psychiatry, social medicine, industrial health, and chronic rheumatism. The fellowships will be open to persons of either sex—usually between the ages of 25 and 35 years—who hold a university degree in medicine registrable in the United Kingdom, who are normally resident there, who are of high merit, and whose ability and inclinations fit them for an academic career in medicine. Candidates on application should already hold the M.R.C.P. or F.R.C.S. Candidates must be recommended by the executive authority of a university medical school in the United Kingdom. They will be expected to have had at least one year's general clinical experience since registration and as a rule to have held residential hospital appointments in general medicine and surgery. A fellowship will be awarded for one year and is extendable, but, save in exceptional cases, will not be tenable for longer than three years. Normally the annual value of a fellowship will be between £900 and £1,300, subject to income tax. A Fellow may not hold any other award concurrently with his fellowship without the permission of the trustees of the Nuffield Foundation. He will be required to carry out, at institutions approved by the trustees of the Foundation, a programme of work and training similarly approved. Other work, paid or unpaid, may not be undertaken without the permission of the trustees. Applications must be received by May 1, 1950. Forms of application are obtainable from the secretary of the Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1.

Bulletin on Narcotics

The United Nations has started publishing a new periodical entitled the *Bulletin on Narcotics*. It is prepared by the Division of Narcotic Drugs. The first number includes articles on the international control of narcotic drugs and opium products throughout the world. The *Bulletin* will publish articles on the scientific and legislative aspects of narcotic drugs and give up-to-date news on their control. The annual subscription for four copies a year is $2, which may be paid in other currencies to the authorized sales agents of U.N. (H.M. Stationery Office in Britain).

Prospective Parliamentary Candidate

Dr. A. D. Robertson has been adopted as prospective Parliamentary candidate by the Motherwell and Wishaw Unionist and Liberal Nationalist Associations.

Film on Food-poisoning

The Ministry of Health has sponsored a new film called "Another Case of Poisoning," which has been produced by the Central Office of Information in collaboration with the Central Council for Health Education. The film takes about 20 minutes to run and shows the many ways in which a patient with food-poisoning may have become infected. Further information about the film can be obtained from the Press Officer at the Ministry of Health.

Sickness Insurance for Women

The directors of the Medical Sickness Annuity and Life Assurance Society, Ltd., state that the present age limit of 35 imposed in connexion with sickness insurance on female lives has now been removed.

Kempner Rice Diet

The Food Rationing (Special Diets) Advisory Committee of the Medical Research Council has recommended to the Minister of Food that supplies of rice and one extra ration of sugar should be made available for the treatment of patients with severe hypertension by means of the Kempner rice diet. The Minister of Food has therefore arranged that patients who on medical advice adopt the Kempner rice diet shall be allowed 4 lb. of rice and one extra ration of sugar a week in place of their allowance of milk and rations of meat, bacon, cheese, and fats. The Advisory Committee considers that there is considerable evidence that a diet consisting entirely of rice, sugar, fruit, and fruit juice as recommended by Kempner (*Amer. J. Med.*, 1948, **4**, 545) will lower the blood pressure in certain cases of hypertension, but that the diet must be rigidly observed if it is to be effective. It points out that the treatment may be not without danger, since progressive renal failure has been observed to occur in patients taking the diet, and the treatment should not be used unless facilities for biochemical control are readily available. Doctors who have not received a copy of Med. 2 (Revised 1948) may obtain one on application to their local food office.

COMING EVENTS

British Association of Physical Medicine

A short course of lectures on the various aspects of physical medicine will be delivered on Tuesdays and Thursdays, from January 3 to February 9, 1950, inclusive, at 5 p.m., and will be suitable for candidates preparing for Part II of the Diploma in Physical Medicine. Further details can be obtained from the honorary secretary, British Association of Physical Medicine 45, Lincoln's Inn Fields, London, W.C.2.

Neurological Teaching

A limited number of clinical clerkships for students who are preparing for the membership or other special diplomas are available at the school for postgraduate teaching in neurology now in existence at the Maida Vale Hospital for Nervous Diseases, London, W. A course of twelve weekly clinical demonstrations open to all members of the medical profession at a fee of £1 1s. will begin on January 6 at 5 p.m. Full particulars can be obtained from Dr. Redvers Ironside, F.R.C.P., dean of the medical school of the hospital.

N.O.T.B. Association

The annual general meeting of the N.O.T.B. Association will be held at 5 p.m. on February 10, 1950, at B.M.A. House, Tavistock Square, London, W.C.1.

BIRTHS, MARRIAGES, AND DEATHS

BIRTH

Bain.—On December 8, 1949, at the Simpson Memorial Pavilion, to Mabel Gertrude (nee Hall), M.B., B.Ch., B.A.O., wife of Dr. A. J. Bain, Craigbinning House, Dechmont, Broxburn, West Lothian, a son.

DEATHS

Brierley.—On December 8, 1949, at St. Olave's, Ramsey, Isle of Man, Edward Edelsten Brierley, M.B., C.M., F.R.C.S.Ed., aged 77.

Brown.—On November 21, 1949, at Adelaide, Australia, Marie Brown, M.B., B.S., D.P.H., wife of Gilbert Brown, M.B., Ch.B., D.A., aged 66.

Caine. On December 12, 1949, at 1, New Chester Road, New Ferry, near Birkenhead, Nathaniel Caine, M.D., J.P.

Champion.—On December 13, 1949, at "Beckets," Framfield, Uckfield, Sussex, Selwyn Gurney Champion, M.D.

Dods-Brown.—On December 11, 1949, John Lawson Dods-Brown, M.B., Ch.B., of Newbridge House, Upwell, Wisbech, Cambridgeshire, aged 32.

Elliott.—On November 28, 1949, at Sea Point, Capetown, South Africa, Charles Caldwell Elliott, M.D., aged 83.

Hannigan.—On December 12, 1949, at Gardenfield House, Drumcollogher, Co. Limerick, Maurice Hermann Hannigan, M.D., D.P.H., late of Botesdale, Diss, Norfolk, aged 91.

Hawkes.—On December 8, 1949, suddenly, Alfred Ernest Underwood Hawkes, M.R.C.S., L.R.C.P., of 41, Penkett Road, Liscard, Cheshire, aged 75.

Liversidge.—On December 15, 1949, at a Harrogate nursing-home, William Liversidge, M.D.

Macfarlane.—On December 14, 1949, Ian William Macfarlane, M.B., Ch.B., of 4 Union Place, Montrose.

MacKessack.—On December 9, 1949, at 83, East Avenue, Bournemouth, Peter MacKessack, M.B., Ch.B., D.P.H., Colonel R.A.M.C., Ret.

Rayner.—On December 6, 1949, Percy Chambers Rayner, M.B., Ch.B., of Barwell, Leics., late of Brook House, Earl Shilton, Leics., aged 78.

Russell.—On December 6, 1949, at St. Anthony's, Crowborough, Sussex, Sir Michael William Hansby Russell, K.C.M.G., C.B., M.R.C.S., Major-General A.M.S., Ret., aged 89.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vaccination Against Smallpox

Q.—*What is considered the best method of vaccination? Is there any truth in the statement that the degree of immunity is directly proportional to the area of foveation? In any case, how can such an immunity be measured? Finally, can you define the term "reaction of immunity"?*

A.—The method of vaccination now officially recommended by the Ministry of Health is the multiple-pressure technique. A drop of vaccine lymph covering an area of about one-eighth of an inch (30 mm.) in diameter is placed on the skin at the prepared site, usually in the region of the deltoid insertion on the left arm. A straight needle, which should be flat-sided or triangular in section (for example, a Hagedorn) and of relatively large size, in good condition, sharp, and sterile, is held parallel or tangential to the arm with the forefinger and middle finger above and the thumb below. One side of the needle point is then pressed firmly and rapidly into the drop about 30 times within 10 seconds, the needle being lifted clear of the skin each time. This rapid up-and-down motion of the needle is in a plane perpendicular to the skin. The needle point is *not* driven into the skin, but at each pressure the elasticity of the skin pulls a little of the epidermis over the point of the needle so that the virus-bearing lymph is carried into the deeper epidermal layers. If the skin has not been unduly irritated by a preliminary cleansing procedure and the needle has been properly aligned, no pain or bleeding should occur and within a few hours there will be no visible signs of trauma.

There is some evidence that the case mortality in smallpox is related to the degree of foveation. Thus, in the Vaccination Report of 1928, case mortality among patients with four scars was 5.4% and increased progressively to 17.9% among those with only one scar. Therefore susceptible persons who are intimate contacts of a case of smallpox should preferably have three or four quarter-inch (60-mm.) insertions rather than the multiple-pressure type of vaccination. There is no infallible test of immunity to smallpox, but failure to vaccinate successfully on two or three successive occasions or the demonstration of complement-fixing antibody is fairly reliable evidence of a high degree of resistance. The so-called "reaction of immunity" is the early local lesion reaching maximum size on the second or third day and characterized by elevation and irritation of the skin but no vesiculation. Such a reaction may be due to sensitivity of the individual to protein or other substances in the lymph and may not be a response to the virus of vaccinia. It should preferably be recorded as "maximum local reaction (non-vesicular) on the second to third day," and if there is any doubt about the potency of the lymph a further attempt at vaccination should be made.

Indications for Digitalis

Q.—*What are the indications for digitalis therapy in patients with normal cardiac rhythm? What is the best method of administration?*

A.—As a broad generalization it may be stated that digitalis is indicated in any case of congestive heart failure. The improvement is not due only to the slowing of the heart, as it often occurs before this is effected. With digitalis therapy in congestive failure the heart volume is diminished and output increased, the rate is slowed, and the force of beat is said to improve. It has also been shown that the right auricular pressure is diminished. In failure secondary to anaemia, emphysema, and thyrotoxicosis, digitalis has hardly any effect, and the primary cause must be treated. The raised right auricular pressure in these cases tends to maintain the cardiac output. Digitalis is also given in cases of rheumatic carditis when it is necessary to control the tachycardia. On recovery from heart failure, digitalis may be continued in those patients whose effort tolerance is so impaired as to interfere with their livelihood; it should not be given in any case of peripheral circulatory failure.

The best method of administration will depend on how urgently the drug is needed and on whether the patient has already been taking it. Rapid digitalization may be obtained by intravenous administration of 1 mg. of "digoxin," given slowly and diluted in 10 ml. of saline. At the same time 2 gr. (0.13 g.) of the powdered leaf may be given every six hours for two to three days, depending on the rapidity of control. The maintenance dose varies considerably, and can be determined only by experience with a particular patient. If the patient has already been taking digitalis, much more cautious dosage is necessary.

Thiopentone in Eye Surgery

Q.—*Is thiopentone soluble or any similar anaesthetic being used effectively and safely in eye surgery, especially for extraction of the lens in cataract operations? If so, are there any contraindications to its use in patients over 70 years of age?*

A.—Thiopentone soluble is being used widely as a safe and effective anaesthetic for cataract operations in cases where a general anaesthetic is desired. Intermittent injections of a 2½% solution or a continuous drip of 0.5% solution are equally satisfactory. Attention to the following points makes for safety. A pharyngeal airway liberally greased with a local analgesic lubricant should be used in every case, and a stream of oxygen allowed to flow into the pharynx throughout the operation. A drop or two of cocaine placed in the eye obviates many reflexes due to operative stimuli, and may avoid the need for large doses of thiopentone. Great care must be taken to keep the airway perfectly clear throughout the operation, and, if the anaesthetist is in doubt about his ability to do this with only a pharyngeal airway in place, he should not hesitate to use an endotracheal tube. In such a case the larynx should be well cocainized to avoid coughing during the operation should the anaesthesia become too light.

There are no contraindications to the use of thiopentone in patients over 70 years of age, so long as it is remembered that the elderly require but small doses of the drug to produce the desired effect. In such patients in particular, heavy premedication should be avoided before using thiopentone as the sole anaesthetic.

Histamine Therapy for Urticaria

Q.—*Could the method of histamine desensitization referred to in "Any Questions?" of May 10, 1947 (p. 666), be used for a boy of 16 who suffers from recurrent attacks of urticaria which respond to treatment with antihistamines, but who is not totally free from urticarial rash? In a bad attack, a saline purgative, together with antihistamines, seems to help in clearing up the rash for a few days. If the method can be used, is it necessary to test for histamine-sensitivity before starting treatment? Urticarial weals of all sizes have been observed, but no "pseudopodia."*

A.—Histamine therapy for urticaria is usually disappointing and has been given up by many workers in this field. A few cases of chronic urticaria appear, however, to do well on this therapy. Preliminary skin-testing with histamine is unnecessary. The following dosage for chronic urticaria is advised by H. L. Alexander (*Synopsis of Allergy*, 2nd ed., Kimpton, London. 1947, pp. 164–5). On the first day two injections of 0.05 ml. of 1 in 10,000 histamine (histamine diphosphate), and on the second day two injections of 0.01 ml., are made. Ten daily injections are then given, starting with 0.15 ml. and increasing each dose by 0.05 ml. up to 0.50 ml. of a concentration of 1 in 10,000. A solution of 1 in 1,000 histamine is then used, and the next two doses are 0.05 ml. and 0.10 ml. of this strength. Five injections are then given every two days, starting with 0.15 ml. of 1 in 1,000 histamine and increasing each dose by 0.05 ml. up to a maximum of 0.30 ml., which is repeated

once. Five injections of 0.30 ml. are then given every three days. According to Alexander (loc. cit.), "One course of treatment may suffice, or further ones may be necessary. If no results occur after 15 or 20 injections, they are not likely to appear." The possibility of food allergy in this case should be considered—and symptoms may occur only when excessive amounts of the offending food are taken. Keeping a food diary and trial dieting might help.

Peptic Ulcer due to Trauma

Q.—*Is there any substantial evidence that a severe blow on the epigastrium might cause a duodenal ulcer? I would be grateful for references and any information.*

A.—A number of cases of probable traumatic gastric or duodenal ulcer have been reported, and the subject has recently been reviewed by Crohn (*Gastroenterology*, 1947, **8**, 735). There seems to be good evidence that local trauma to the upper abdomen can result in a peptic ulcer which manifests itself within a few days. Although the psychosomatic aspect is difficult to exclude, it is probable that submucosal and intramucosal haemorrhages may be followed by ulceration, and this has been observed gastroscopically.

Acquired Allergy

Q.—*A married woman of 35, with no personal or family history of allergy, had a liaison with a man who had such a history, and as a result she became pregnant. Her child developed infantile eczema during his first year. Twelve months later the liaison was resumed for one week, when a contraceptive paste was used. The following week she had severe generalized urticaria with slight asthma. Adrenaline gave prompt but transient relief, and the condition cleared slowly with antihistamines. Is it a tenable theory that she was sensitized by her child during pregnancy to a factor provided during intercourse by the child's father?*

A.—No, she could not be sensitized by her child or by the father. In children with very early allergic manifestations it is usual to obtain a history of allergy in both parents; it is therefore suggested that if the patient made a more careful inquiry she would find that she had a family history of allergy. In all probability her present symptoms are due to psychological disturbances. It may be, also, that they had nothing to do with her liaison and that the association was accidental. Possible allergens which might be suspected are quinine or some other drug used in the contraceptive paste, or foods such as chocolate or fruit which she may have eaten in excess at that time.

Unsuccessful Injection of Varicose Veins

Q.—*For the first time in 13 years' experience of injecting varicose veins I have met a patient who resists every attempt at inducing thrombosis. There is no fault in technique, and she tells me that doctors in the Services had the same experience. Why is this? What happens to the sclerosing solution? Can you suggest a remedy?*

A.—There are now and again cases of this type. The twin injection of quinine and salicylate sometimes succeeds and so does 30% saline. Ligation of the veins with simultaneous injection in the orthodox way, however, always achieves thorough thrombosis.

Survival of the Flea

Q.—*Is it known how long the common flea (Pulex irritans) can survive in an empty house? What is the best means of cleansing an infested house?*

A.—Many varieties of flea are adapted to survive for long periods in the absence of their host. The larval flea develops to the adult stage and then waits, resting in its cocoon, until the disturbance caused by a returning host indicates the presence of a further source of blood meals. The human flea is no exception to this general rule and can certainly survive several months, in the cocoon, in an empty house. Bacot (1914) records an average of 116 days' survival at 53° F. (11.65° C.); the maximum period he observed was 239 days. To eradicate a heavy infestation it may be desirable to employ fumigation experts to disinfest with hydrogen cyanide. It should, however, be possible to destroy the fleas by scattering flake naphthalene over the floors (about 4 lb. (1.8 kg.) per room) and leaving the rooms sealed up for a day or so. For fuller details see the *Monthly Bulletin of the Ministry of Health and Public Health Laboratory Service*, October, 1944.

NOTES AND COMMENTS

Acute Nephritis and Sweating.—Miss H. COOPER (sister tutor in the preliminary training school, General Hospital, Birmingham) writes: In Dr. Charles Romer's letter (November 12, p. 1128) he questions whether patients suffering from acute nephritis "tend to sweat excessively." As sister tutors we teach that a blanket bed is used for nursing these patients, not because they do sweat but in order to induce sweating and increase the amount of fluid loss. This seems reasonable, since the important balance between the activity of the skin and the kidneys is upset in acute nephritis. Patients suffering from acute rheumatism, on the other hand, do in fact tend to sweat, and the use of blankets in these cases is to provide a material next to the skin which will readily absorb perspiration. We have always tried to teach the physiological reasons underlying the use of these beds and have emphasized our different aim in each case. Nevertheless we feel that the value of the amount of diaphoresis induced by the use of blankets next to a patient suffering from acute nephritis is outweighed by the discomfort which this causes to some patients. We would suggest that in future it would be better to teach the use of one soft blanket next to the patient wherever it adds to the comfort of that patient—e.g., aged or very thin people—rather than to emphasize the questionable diaphoretic value of blankets next to the skin in the case of acute nephritis.

Proguanil as a Malaria Suppressant.—Dr. CH. W. F. WINCKEL (Amsterdam) writes: Under the heading "Any Questions?" (November 26, p. 1245) your expert on malaria ended his answer to a question on proguanil as a malaria suppressant as follows: "The frequency of relapses of vivax malaria may be reduced by taking one of the 8-aminoquinoline drugs—for example, pamaquin, 0.01 g. thrice daily for 10 to 14 days; with each dose of the drug it may be more effective to combine quinine 0.6 g. or mepacrine 0.1 g." This alternative might lead to confusion, and therefore I should like to make the following remarks: (1) It is very unusual to treat attacks of vivax malaria (*a fortiori* of falciparum malaria) with pamaquin only, as this drug is rather poor as a schizonticide, whatever its merits as a gametocide, and especially as an anti-relapse drug. (2) For this reason the combined use of pamaquin and a schizonticidal drug is recommended in every textbook on tropical diseases. (3) Usually only quinine is recommended for this purpose, mepacrine being seldom recommended, for the simple reason that the combination of pamaquin and mepacrine is too toxic. It would not be difficult to quote many authors who express this opinion. It may suffice to mention Manson's *Tropical Diseases*, 1946, London, p. 103, which states: "The simultaneous exhibition of 'atebrin' and 'plasmoquine' is not to be recommended, as it may cause alarming symptoms."

Breathing Through a Closed-circuit Apparatus.—Dr. W. N. ROLLASON (Scunthorpe, Lincs) writes: Your answer in "Any Questions?" (October 29, p. 1000) on breathing through a closed-circuit apparatus reminds me of a leisure hour I spent nearly four years ago breathing through a Coxeter-Mushin closed-circuit machine with a basal oxygen flow of 500 ml. As reported in the *Journal* of January 19, 1946 (p. 106), my pulse varied between 72 and 68 and my respirations between 16 and 14. I experienced slight discomfort towards the end due to the pressure of the face-mask, but otherwise no untoward effects during or after the inhalation.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY DECEMBER 24 1949

THE SECRETARY REPORTS

PUBLIC HEALTH MEDICAL OFFICERS

In this column a fortnight ago attention was drawn to the problems arising for those members of the public health service who before the N.H.S. appointed day were whole-time officers of local authorities and whose duties included commitments as medical superintendents or medical officers of infectious-diseases hospitals and similar institutions. The Public Health Committee intends to pursue this matter through the appropriate committee of the Whitley Functional Council early in the new year. After all, this is just the sort of problem for which the Whitley machinery was devised, and it is a matter for some surprise that this point should not have occurred to the Ministry. Meanwhile the committee desires to repeat the advice already given to local authority medical officers who are asked by regional hospital boards to accept contracts for part-time services. That advice is to defer action until the present discussions are completed.

The committee's view is that under no circumstances should a public health medical officer accept a contract for hospital work in the grade of junior hospital medical officer. In cases where pressure is brought on an officer to undertake hospital work in this grade it should be undertaken only on the understanding that the arrangement will be regarded as temporary in character and subject to revision in the light of the Public Health Committee's discussions. Incidentally, there seems to have been a lack of uniformity between the various regions in the classification of their public health medical officers in relation to their infectious-diseases work. In one large region it appears that the public health officers engaged in this work, some of them of high standing and long experience, have been classified, willy-nilly, as senior hospital medical officers. Inquiry is being made into the position.

Vaccination and Immunization

Negotiations on the fees for vaccination and immunization have at last reached conclusion. The local authorities' associations have agreed to recommend their constituent bodies to pay a fee of 5s. for each record received from a general practitioner. This fee will be paid for evidence of a successful vaccination on the first attempt, or where a second attempt has been made after an unsuccessful first attempt. A third attempt will be regarded as a fresh vaccination and an additional fee of 5s. will be paid for it. In the case of immunization, the fee will be paid in respect of the complete process, normally involving two injections.

The General Medical Services Committee has accepted these terms on the understanding that they will apply retrospectively to all cases for which a record has been returned since July 5, 1948, and without prejudice to the reopening of the question of the fee in the light of changed circumstances. The committee has also asked that every effort be made to simplify and standardize the form of report required by local authorities.

Other General Practice Matters

By the end of December we shall have completed the first three months of the statistical inquiry which has been undertaken, under the guidance of an eminent statistician, to determine the number of items of service rendered by general practitioners under the National Health Service. In addition to the usual items such as visits and consultations at the surgery the inquiry will reveal a number of special items of service—e.g., reports, certificates, night visits, etc. The object of the survey is to assess the amount of work which is being undertaken by general practitioners in the light of the committee's view that in devising its recommendations the Spens Committee based them on the assumption that the doctor would do a reasonable day's work and be left with sufficient leisure.

The Ministry has agreed that all sulphonamides should be included in the list of specially expensive drugs for which additional payment is made in the case of those practitioners who are dispensing practitioners. The Ministry has also agreed that, where drugs and dressings are supplied by a dispensing practitioner who is providing maternity medical services for a patient on another practitioner's dispensing list, the cost can be covered by prescribing the drugs and dressings on the ordinary prescription form (E.C.10), which should be passed to the executive council.

Owing to a legal difficulty the Ministry has not yet been able to promulgate the arrangements agreed with the General Medical Services Committee under which doctors associated with residential schools will be able to prescribe in bulk on a single prescription form drugs for the use of the school as a whole. It is understood that the necessary regulation will be issued now that the Royal Assent has been given to the National Health Service (Amendment) Act.

The committee is still awaiting an invitation from the Ministry to discuss proposals for giving effect to the Government's decision to make a charge of not more than one shilling (subject to certain exceptions) for prescriptions under the National Health Service. All will agree that the doctor should not be required to play any part in the collection of this charge.

A special committee of the General Medical Services Committee has been set up to consider any modification or amendment which may be desirable in the Medical Services Committee procedure as laid down in the Service Committees and Tribunal Regulations, 1948.

Residential Appointments

I suppose no one can complain at being called upon to pay his legitimate income tax—by that I mean to complain more than usual—but the fact remains that a number of practitioners, notably resident hospital officers, including medical superintendents, will pay more tax under the new arrangements than they did under the old. This happens not because of new legislation but because of a change in the way of expressing an officer's position in relation to emoluments.

Under their former conditions of service many hospital medical officers received a net salary, plus residential emoluments in kind which were not taxable. The Board of Inland Revenue has intimated that as from July 5, 1949, these officers will be taxed on the basis of their gross salary, but for the period July 5, 1948, to July 4, 1949, only the actual cash arrears will be taxable. In other words the intention is to tax net salary up to July 4, 1949, and gross pay thereafter.

The salary scales laid down in the terms and conditions of service for hospital medical staff are for non-residential officers, and, where board and lodging or other services are provided, are subject to deduction.

In the case of house officers the deduction is at the fixed rate of £100 p.a., *but for all other officers* the charge is determined by the hospital management committee (or board of governors) at a sum equal to the value of the services provided. It is not uncommon therefore for a house officer and a registrar to occupy similar quarters at very different charges. Where the officer is appointed by a regional board, the charge fixed by the hospital management committee is subject to the approval of the board.

HOSPITAL AND SPECIALIST SERVICES IN SCOTLAND

The following memorandum has been issued by the Department of Health for Scotland:

The tables which follow this memorandum have been constructed on returns which were obtained from the five Scottish regional hospital boards in September, 1949. These returns covered the specialists, including both consultants and S.H.M.O.s, who were at that time in contract with the regional boards. For each individual was recorded his year of birth, his grading, the specialty in which he was engaged, the hospital group (or the principal one) to which attached, whether whole-time, part-time (including the number of notional half-days employed per week), or under a main contract with the university and a parallel contract with the regional board.

These returns were transferred to punched cards and have been analysed as set out below. The process is still incomplete, but the preliminary results have appeared so deserving of urgent consideration that the tables and certain deductions from them are now set out for the information of the regional hospital boards, the universities, and the profession.

Certain reservations must be made. In the interval between receipt of returns and their analysis some deaths, retirements, promotions, and new appointments have occurred. Some 60 appeals against grading are pending and have still to be decided. In the tabular grouping it has from time to time been necessary to associate certain groups—for example, pathologists include biochemists, as well as certain other laboratory specialists whose field may include bacteriology. Some specialists are included in the general surgical or general medical groups although they may also have an interest in special fields.

It is believed, however, that these and other sources of possible error do not seriously invalidate the general tables and the conclusions to which they seem to point. The total number of individuals included in these tables is 920. Of these, 646 hold consultant grade and 274 are graded as S.H.M.O.s.

Further studies are in progress, including an estimate of the distribution by age groups and locality of the general practitioners in contract with executive councils, and further tables will show the number of new medical practitioners and medical students who register for the first time in each year in Scotland and England and Wales. At a later stage it is intended to make a similar analysis of all registrar appointments. And, finally, the tables will be kept up to date by quarterly returns from the boards showing deaths, retirements, transfers, and new appointments.

Young Specialists

The first impression from a study of the specialist age groups is that the specialists are, in the mass, a comparatively young community. The year-of-birth period covers almost exactly 40 years. Only two consultants in the Service were born before 1880; only three S.H.M.O.s subsequent to 1919. The age distribution between the four 10-year periods is:

	Date of Birth			
	Before 1889	1890–9	1900–9	1910 and After
	(60 and over)	(50–59)	(40–49)	(Under 40)
All specialists, consultants, and S.H.M.O.s	85	210	305	320
Percentage of total (920) (to nearest whole number)	9	23	33	35

It will be seen from the tables showing the age groups by five years (and still more clearly from the original extended tables) that there are "peaks" at the age groups surrounding 1901 and 1911 (year of birth). Individuals born in these years would graduate, say, between 1922 and 1926, and 1932 and 1936, respectively. The comparatively heavy "crop" of specialists in these age groups may be referable, in the first group, to the great accession to the *Medical Register* in the years following the first world war (over 2,500 in the peak year 1925).

It is significant that this last figure was equalled in 1938 and has been exceeded in almost each subsequent year. It still remains to be estimated what proportion of new graduates in the years since 1938 may have turned to specialist work, but, given the same preferences as held for the 1922–6 and the 1932–6 graduates, it will be high. It seems clear, too, that the numbers added to the *Medical Register* in each of the next few years will exceed any previous "normal" additions. The graduates of 1950 and onwards will include numbers of demobilized ex-Service men and women who returned to civil life and took up studies in 1945 and subsequent years and to accommodate whom the medical schools increased the number of available places. The tables are, therefore, of special interest for the indications they afford, however limited, of the prospective vacancies in specialist appointments.

Vacancies

Vacancies in the specialist service may occur through death, through retirements, or through an actual increase in the establishment of specialist posts. It is not, of course, practicable to assess precisely the opportunities which specialists trained in Scotland may find elsewhere in the United Kingdom, in the Services, or abroad. With this reservation, the numbers of specialists in training at any one time—that is, the numbers in registrar appointments—should be related to the prospective vacancies.

There cannot at present be any certainty as to the number of new specialist posts that may be created in the next few years. The more obvious gaps—in the landward areas and in certain specialties—are being filled now, and further expansion of the specialist services cannot proceed far in advance of expansion of the hospital and out-patient facilities and in the numbers of nursing and other ancillary staff. These may prove limiting factors. It is safer, therefore, to confine examination for the present to the numbers required to maintain the existing specialist establishment.

Retirements can be calculated from the numbers in the various age groups. The normal retirement age in the Service is 65, though boards may agree with individual specialists to extend their contracts, perhaps with modifications, to the age of 70. That is, specialists born in 1885 or earlier should normally retire before the end of 1950. The numbers concerned are:

Consultants	28
S.H.M.O.s	6
Total	34

In subsequent years the number of estimated "normal" retirements are:

	1951	1952	1953	1954	1955	1956
Consultants	6	13	17	10	12	13
S.H.M.O.s	1	—	3	1	4	3
Total ..	7	13	20	11	16	16

distributed over the whole specialist field. Whether all these retirements would mean individual replacements would have to be decided at the time. Some certainly would; others representing posts on part-time contracts, with a limited number of sessions, might not. Some S.H.M.O.s will no doubt be replaced by consultants.

As well as losses from "normal" retirements there is a calculable loss from mortality over specialists in all age groups. Calculation shows that this number would be around 10 per annum and may be less in the next few years because of the age distribution.

Registrars

These calculations suggest that an output of trained registrars of not more than 30 per annum would adequately fill the prospective vacancies for some years to come over the whole specialist field.

The number of registrars in each grade—junior registrar, registrar, and senior registrar—will no doubt be progressively reduced so as to select from the initial entrants to the registrar grade only those capable of filling specialist posts. This qualitative selection should presumably be accompanied

by a quantitative reduction so that the numbers emerging as trained specialists roughly approximate to the prospective vacancies—in Scotland and elsewhere. The proper rate of reduction at each of the several years of the registrar's training is a matter for consideration. The number of senior registrars in each year of training should presumably be related closely to the annual expectation of specialist vacancies. The number of registrars in each year has to be greater than the number of seniors and the number of junior registrars greater than the number of registrars. For example, one estimate is that for every 30 specialist posts that fall vacant each year the appropriate numbers of registrars in training might be:

Senior Registrars	
(? Fourth year	30)
Third year	30
Second year	30
First year	30
Registrars	
Second year	40
First year	60
Junior Registrars	90
Total No. of Registrars	280 (+ ? 30)

If the process of selection is more severe the numbers in the earlier years might be greater, and conversely.

As 30 has been taken above as the number of vacancies in existing posts that will occur annually in Scotland in the next few years, the total number of registrars in training necessary to fill these posts would be about 300.

Allowance has to be made, of course, for new posts and other needs outside Scotland, but even so it seems necessary to consider whether the numbers of registrars and others at present in training to be specialists are justified by their prospects of obtaining specialist posts.

It is also necessary to consider the needs of the hospitals for medical staff below the specialist level in order to carry on the essential work. There may prove to be a substantial difference between the number of registrars which the prospect of specialist posts would warrant and the number of doctors of this level of experience who are actually needed in posts the bulk of which have in the past been filled by specialists in training. A situation of this kind might well require some reconsideration of the basis of hospital staffing, the relative responsibilities of specialists and registrars, and the scope for hospital posts outside these two categories.

SURVEY OF CONVALESCENT HOMES

The Ministry of Health has asked regional boards to undertake in association with local health authorities a fact-finding survey of the untransferred convalescent homes in their regions. This survey is to be carried out instead of a review, formerly asked for, of the untransferred convalescent homes with a view to their allocation for use either by boards or by local health authorities. In the survey the homes will be put into one of the following categories:

(*a*) Those which provide convalescent treatment within the scope of the hospital service, and may therefore be appropriately used by regional hospital boards.

(*b*) Those which provide recuperative facilities of the "holiday home" type, and may therefore be appropriately used by local health authorities.

(*c*) Those which are a combination of (*a*) and (*b*).

When this information is available consideration will be given on a national basis to the question whether there should be any, and if so what, allocation of convalescent homes or beds between regional hospital boards and local health authorities.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby.

DOCTOR TO PAY EXPENSES

In a case that came before a medical service committee recently a man complained that his daughter was not visited by a doctor when the doctor was called by telephone.

Mr. A wrote to the clerk of the executive council of his area saying that at about 6 p.m. his daughter complained of slight earache, which his wife treated. After 8 p.m. the pain became worse; by 10.15 p.m. the child was in agony, which showed no sign of abating by 11 p.m. Mr. A then telephoned Dr. X. Dr. X came from his bath to answer the telephone, and, according to Mr. A, on being told about the child's pain said, "Well, what can I do about it?" Mr. A protested at this remark, and said that the doctor told him not to be silly, that he had nothing for the child at home, and that he could only give a prescription which could not have been made up until the morning. Mr. A got very angry and rang off. At 4 a.m. the same night Mr. A telephoned a Dr. Y, who visited the patient within a few minutes, and treated her. The next morning a surgeon performed a minor operation on the child, and she made an uneventful recovery.

A copy of Mr. A's letter of complaint was sent by the clerk of the executive council to Dr. X, who agreed that the facts in it were correct. Dr. X added in his reply that he considered he was entitled to be annoyed about the telephone call at 11 p.m. Twice on that evening he had been near Mr. A's house between 6 p.m. and 9.30 p.m. and would have been pleased to visit Mr. A if he had been more considerate and telephoned sooner. Moreover, he had intended to comply with Mr. A's telephoned request, but considered he was entitled to argue the matter first.

In verbal evidence Mr. A admitted that owing to the abrupt termination of the telephone conversation he did not expect Dr. X to attend the child that night, but thought he would come on the following morning. He had felt reluctant to call the doctor unless it proved absolutely essential to do so.

Dr. X contended in his verbal evidence that a large proportion of "urgent" calls had proved to be unnecessary, and that he was therefore entitled to discuss the case on the telephone. He insisted that he had not refused to attend, and if Mr. A had not rung off so suddenly he would have undoubtedly made the visit.

Inferences by Committee

The committee considered that the doctor's failure to visit the patient was due to the nature of the telephonic exchanges between him and Mr. A. The committee thought it reasonable for Mr. A and his wife to try to alleviate the child's immediate distress and to avoid, if possible, the need for calling in the doctor, and it was satisfied that Mr. A had not sought Dr. X's services until he had formed the opinion that such services were absolutely necessary.

Deduction from Pay

The executive council adopted the committee's recommendation that an amount be recovered from Dr. X's remuneration equal to any medical expenses incurred by Mr. A as a result of his requisitioning the services of another general practitioner in a private capacity, and that such amount be paid to Mr. A.

Correspondence

Unreasonable Demands by Regional Boards

SIR,—Sir Reginald Watson-Jones's timely letter (*Supplement*, December 10, p. 253) prompts me to record a recent but by no means unique experience, which is best described by giving the substance of a letter of protest that I sent to the chairman of the regional board concerned.

"Yesterday morning (November 30) I received a cyclostyled letter, even the signature being duplicated, asking me for a private and confidential opinion about a candidate for the post of orthopaedic surgeon to the ..... Hospital Management Committee. I was asked to send my reply *before Saturday, December 3*.

"The format of the letter is, perhaps, excusable, though no such labour-saving devices are permitted to those who reply to these inquiries—and one may have many to answer.

"What is serious and, I think, unpardonable is the short interval between the posting of the request and the date for sending in the reply. . . . Tomorrow I am going to —— to give a lecture, and I shall be away from the hospital for two days. It is pure chance that this absence did not coincide with the arrival of the letter about the —— candidate, and then I should have been unable to send an answer in time for the meeting of the advisory committee. In that case my silence might have been open to very serious misrepresentation. . . .

"I am not unaware of the heavy responsibilities of regional boards, but surely it must be acknowledged that the selection of the best men for senior vacancies in the Health Service is by far the most important of the manifold duties of regional boards and boards of governors. The man you appoint will make or mar the Health Service. If referees are to do their job conscientiously they must be given time in which to write considered opinions about candidates, and allowance must be made for possible short absences from their normal places of work."

No reply has yet been received.—I am, etc.,

London, W.1. H. J. SEDDON.

Protection from Patients

SIR,—We youngsters serving in the Forces read with dismay the alarming accounts of N.H.S. patients who send lists by post of all the articles which they require their doctor to prescribe. It seems that, unless we are to lose patients from a very meagre panel at a time when we need them most, when we return to general practice, we shall be forced to give in to this blackmail.

Is this outlook widespread among our future patients? Can our senior colleagues advise us on how to protect ourselves against these and similar "things that go bump in the night"? It will be many years before we have acquired their degree of tact and independence to protect ourselves.—I am, etc.,

M.O. OVERSEAS.

As Others See Us

SIR,—The following extract from a friend's letter requires no comment of mine. I should introduce the extract by saying that my friend's daughter, aged 7, had run in front of a bus, which in avoiding her had skidded and pinned her foot against the kerb. The child has been warned repeatedly to take care in crossing the road, but is rather an obstinate mite.

"I sent for doctor, who came fairly quickly. Ankle swollen, but he said it wasn't much; rest for two days and then come to surgery. The child was very shaken up, so I put her to bed for a day although the doctor said I needn't. I couldn't walk her down to the surgery, as it was still swollen, so I asked him to call, wishing that we were private patients. He called, and I said we wanted an *x*-ray as it was still swollen. Then for three days we spent several hours waiting at the hospital. It took four hours at first, then the next day about an hour and a half. The third day there was the clinic at the orthopaedic department. There was such a crush you couldn't get in at the door. Once inside the holy of holies I got ticked off by a nurse for saying goodbye to someone I'd met. 'You mustn't talk in here,' she said. The doctor wouldn't let me see the *x* ray. 'Only a slight break,' he said, 'only slight.' Why must one be treated as an imbecile?

"We go again on Monday to have the plaster removed. I hope I don't get ticked off again—I may answer back next time."

I would only add that my friend lives in a large town. How good it is to see ourselves as others see us.—I am, etc.,

Isleworth, Middlesex. F. PYGOTT.

Ham and Offal

SIR,—May I cap your very interesting anecdote (*Supplement*, December 3, p. 239)? I happened to be in the office of the Lady Margaret Fruitarian Hospital and so answered an urgent and imperious 'phone call: "Please send round at once to Lady X two kidneys or a liver."

I had to decide promptly whether to reply, "This is a fruitarian hospital and not the butcher's shop," or, "We are not operating to-day."—I am etc.,

London, W.1. JOSIAH OLDFIELD.

Country Doctors Near Towns

SIR,—I believe mileage payments for rural areas were intended to encourage doctors to settle in these areas. I live in a village of about 1,300 people, surrounded mainly by urban areas. When a patient of a doctor from one of these areas moves into this village, the doctor is encouraged to continue to attend him by the payment of a mileage fee. Yet, when one of my patients moves out into one of these urban areas, I do *not* receive mileage payment.

The argument is advanced that rural practitioners would be able to build up substantial lists in urban areas, with the consequent diminution of the mileage rate. This argument is specious, since in any urban area a patient has choice of several locally resident doctors and is most unlikely to call in a doctor from several miles away, and I find that my list in these urban areas does not grow appreciably, although I believe I give reasonable service, since I practically never lose a patient except by death or removal.

I should like to hear the views of other rural doctors living near urban areas. My contention is that either a doctor living in a rural area should be eligible for mileage payments for urban patients living over two miles away, or doctors living in urban areas should *not* be eligible to receive mileage payments.—I am, etc.,

Stockport, Cheshire. JOHN HEGINBOTHAM.

Patients in Scottish Camps

SIR,—As a rural practitioner in a sparsely populated area who cannot normally expect to increase my small list of patients to any extent, it is somewhat disconcerting to find that when by chance a few hundred workmen are added to the population for a year or two I am remunerated at the cut-price rates of 12s. 6d. per annum for medical attention to these men and 4s. for drugs.

I refer to men stationed in two North of Scotland Hydro-electric Board camps in my area. Because of the frequent changes in personnel these men do not come on to my list, but by arrangement with the Department of Health for Scotland I am paid according to the average number in the camps based on weekly returns.

The Department, on being approached on the matter, maintained that because the men were concentrated in a limited area this was regarded as an advantage in that more attention could be given to a greater number in a given period of time. Secondly, the Department maintained that the workers went home in serious illnesses or were removed to hospital and therefore the services rendered were less than for ordinary Health Service patients.

The two camps are 10 and 11¼ miles from my house, and there is little difference between visiting men sick in scattered huts and visiting patients in a village. As to the Department's second argument, over 80% of the men are Irish and do not go home. They are put in the camp sick-bay if the illness is slight or in the cottage hospital if more severe and in both places are treated by me.

It is appreciated that some of these men are on the lists of other doctors, but surely those who do the work deserve the reward. It would be interesting to know the views of others similarly affected. My feeling of injustice is not lessened by the fact that I have to date received no payment at all for 1949.—

I am, etc.,

DAVID M. WALKER

Strone, Argyll.

POINTS FROM LETTERS

Mutual Support

Dr. DUDLEY F. TORRENS (Market Rasen, Lincs) writes: Medicine is beleaguered. We must pool our incomes and divide them fairly. Pay each practitioner's rent and rates. Pay a per caput subsistence allowance to each medical family. Pay a travelling allowance to each practitioner proportionate to his petrol allowance. Pay an allowance proportionate to each practitioner's surgery expenses. Pay a per caput educational allowance in families where it is needed. This means a sacrifice for those who are above the average in income and an alleviation for those who are below the average. That is not so important. What *is* important is that such action would mean *unity*. At present the fortunate professional man does not really support the unfortunate. He does in theory. This is not a strike. It is mutual support in *doing*, not in refusing to do. It is ethical as between doctor and doctor, as between doctor and patient, as between all doctors and the State. It would soon demonstrate whether the attitude and estimate of the State was right, or that of the profession. . . .

Temporary Surgeon Lieutenant D. P. Finnegan has been transferred to List II of the Permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

ARMY

Major-General J. C. A. Dowse, C.B., C.B.E., M.C., K.H.P., late R.A.M.C., having completed four years in the rank, has been retained on the Active List supernumerary to establishment.

Brigadier (Temporary Major-General) T. Menzies, O.B.E., late R.A.M.C., to be Major-General.

Brigadier T. Young, O.B.E., late R.A.M.C., to be Major-General (supernumerary).

Colonel A. J. Beveridge, O.B.E., M.C., late R.A.M.C., to be Brigadier.

Colonel B. J. Daunt, O.B.E., late R.A.M.C., having attained the age for retirement, is retained on the Active List supernumerary to establishment.

Colonel F. C. K. Austin, late R.A.M.C., has retired on retired pay.

Lieutenant-Colonels E. H. Hall, O.B.E., A. Sachs, and G. A. Walmesley, O.B.E., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel C. G. G. Keane, O.B.E., has retired on retired pay, and has been granted the honorary rank of Colonel.

Lieutenant-Colonel J. G. E. Vachell has retired on retired pay.

Lieutenant-Colonel T. J. Moloney has been placed on half-pay on account of disability.

Majors (War Substantive Lieutenant-Colonels) A. M. Pugh and J. D. Cruickshank to be Lieutenant-Colonels.

Majors D. Wright, D.S.O., and G. C. Dansey-Browning to be Lieutenant-Colonels.

Major J. G. Peacock has retired, receiving a gratuity.

Captains A. J. Moss-Blundell, E. M. Ensor, H. M. Macfie, and R. G. McFarlane to be Majors.

Short Service Commission.—The notification regarding Major J. C. Scott in a *Supplement* to the *London Gazette* dated July 22 has been cancelled. Captain R. M. B. Talbot has retired, and has been granted the honorary rank of Major.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel K. S. Fitch, O.B.E., I.M.S. Ret., to be Lieutenant-Colonel.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Colonel W. McK. H. McCullagh, D.S.O., M.C., T.D., has been appointed Honorary Colonel, a new appointment.

Colonel R. Ward, M.C., T.D., having exceeded the age limit, has retired.

Major (Honorary Lieutenant-Colonel) R. Passmore, I.M.S., retired, to be Major, and has been granted the acting rank of Lieutenant-Colonel.

Captains (acting Majors) R. H. Moore and E. N. Owen to be Majors.

Captains D. S. Dick, A. C. Houghton, C. J. Mackinlay, and J. R. D. Williams to be Majors.

Lieutenant F. C. Rodger to be Captain, and has been granted the acting rank of Major.

ROYAL AIR FORCE

Group Captain J. B. Gregor has retired.

Flight Lieutenant C. R. Griffin to be Squadron Leader.

To be Squadron Leaders (temporary): W. Laurence and Mary G. Murphy.

Flight Lieutenant M. Mattinson has relinquished his commission, retaining the rank of Squadron Leader.

Flying Officer J. N. Agate to be Squadron Leader.

ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron Leader W. Laurence has relinquished his commission on appointment to a temporary commission in the R.A.F.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Squadron Leader M. G. Murphy has relinquished her commission on appointment to a temporary commission in the R.A.F.

Flight Lieutenant M. E. G. Sherwell to be Squadron Leader.

INDIAN MEDICAL SERVICE

Lieutenant-Colonels W. Lawie, E. T. N. Taylor, C.I.E., M. P. Atkinson, J. P. J. Little, G. J. Joyce, and W. Fleming have retired.

Major T. C. McG. McD. Morrison has retired and has been granted the honorary rank of Lieutenant-Colonel.

COLONIAL MEDICAL SERVICE

The following [illegible] announced: W. Richmond, M.B., Medical C[illegible] Northern Rhodesia; V. F. Wilkins, M.B., [illegible] Nigeria; N. T. Pease, M.B., D.C.O.G., Medic[illegible], J. K. Hunter, M.B., D.P.H., I. W. Mackeilan, M.B., D.T.M.&H., and W. A. Wilson, M.B., D.T.M.&H., Senior Medical Officers, Uganda; W. A. Glynn, M.R.C.S., Senior Medical Officer, Nyasaland; M. L. McCauley, M.B., Senior Medical Officer, Fiji; D. R. McPherson, M.B., D.M.R.E., D.T.M.&H., Specialist Radiologist, [illegible] Federation of Malaya; J. R. P. Murley, M.R.C[illegible] Nigeria; R. H. Purnell, F.R.C.S., Surgeon [illegible] G. A. Ransome, M.R.C.S., M.R.C.P., Chair[illegible] Edward VII College, Singapore; H. G. H. Waters, B.M., D.T.M.&H., Senior Medical Officer, Kenya; H. M. Johnson, M.B., M.P.H., Medical Officer (Health), Jamaica; E. S. Monteiro, M.R.C.P., Chair of Clinical Medicine, King Edward VII College of Medicine, Singapore; Constance E. Field, M.D., Child Health Specialist, Federation of Malaya.

The Ministry of Health has notified executive councils that a revised Form E.C.1 will come into use from January 1. The form can be used either for a first application to be placed on a doctor's list or for transfer to another doctor when the medical card is missing. It will be available only at doctors' surgeries, executive council offices, and, on the registration of a birth, from the Registrar of Births. Form E.C.1 itself has already been withdrawn from post offices and public libraries to help reduce the risk of inflation of doctors' lists.

Association Notices

REGISTRARS' GROUP

Following the approval of the Council to the formation of a Special Group of Registrars within the framework of the Association, members who are engaged in one or other of the registrar grades are invited to apply for membership of the Group on the form set out below. Further supplies of the application form may be obtained on request.

Applications should be sent to the Secretary.

BRITISH MEDICAL ASSOCIATION

REGISTRARS' GROUP

Form of Application for Membership

To the Secretary,
British Medical Association, B.M.A. House, Tavistock Square, London W.C.1.

I wish to apply for membership of the Registrars' Group of the Association, and understand that the inclusion of any individual member within the Group is at the discretion of the Group Council subject to appeal to the Council of the Association.

I am a member of the Association, and am engaged as a hospital registrar.

Meetings of Branches and Divisions

BOURNEMOUTH DIVISION

At a meeting of the Division held at Boscombe, Bournemouth, on November 25, Dr. G. D. Kersley, Director of the Rheumatism Research Unit, Royal National Hospital for Rheumatic Diseases, Bath, gave an address on "Recent Advances in Connexion with Rheumatism and the Endocrine Glands." In addition to an up-to-date résumé on endocrinology in relation to the rheumatic diseases, including gout, Dr. Kersley referred to the interrelationship of the pituitary adrenal cortex and the collagen diseases. He also discussed the possible control of hereditary hyperuricaemia in gout and recent work on the endocrine glands and the ageing process of bone in osteoarthritis. The address was much appreciated by the Division, and after questions and discussion a vote of thanks was accorded to the lecturer on the proposition of the chairman, Dr. O. C. Carter.

A QUANTITATIVE APPROACH TO THE STUDY OF TRANSPLANTABLE TUMOURS*

BY

JAMES CRAIGIE, O.B.E., F.R.S.

A period of intense experimental activity was ushered in when it was discovered, at the end of the last century, that some rat and mouse tumours could be transplanted. The discovery was made by Hanau, in Germany, and Moreau, in France, and was confirmed by Loeb and by Jensen. The significance of the introduction of the simple technique of tumour transplantation is that it removed a limitation that had greatly impeded progress, the limitation of the study of a tumour to the animal in which it had arisen. With the means of indefinitely prolonging the life of a tumour available, experimental oncology developed rapidly. Much substantial progress was made, but many hopes remained unfulfilled or were proved to be built on imperfect knowledge and misunderstanding of the available facts. I make reference to these disappointments because I feel that the title of this lecture may perhaps suggest an undue and unwarranted degree of optimism about the amount of useful information that remains to be gathered by transplanting tumours from one animal to another. There are many lessons in the mistakes and disappointments of the early period of study of transplantable tumours which should not be forgotten in the conduct of any branch of cancer research.

A number of important facts emerged from the work of Loeb, Jensen, Borrel, Ehrlich, Apolant, Bashford, Murray, Haaland, Woglom, and others on transplantable tumours. Those which are relevant to my subject may be summarized very briefly.

Serial passage of a tumour is possible only in the species in which it arises, and within the species is usually restricted to animals of the same genetic constitution. The importance of genetic background is due to the fact that transplantation is dependent on the inoculation of living tumour cells which, since they retain genetic characteristics of the original host, are rejected by a genetically alien one. A pedigree of tumour cells remains unbroken throughout the history of transplantation of the tumour. Each successive host provides anew at each transplantation the vascular supply and stroma necessary for continued growth of the tumour. There are of course exceptions to this continuity of cell pedigree. The carcinogenic viruses—namely, the Rous and other avian viruses, the Shope papilloma virus, and others—will produce tumours *de novo* by infection of cells of the host. Again, a transplantable carcinoma may sometimes be replaced by a sarcoma, or a tumour specific for one inbred strain of mice may acquire the ability to grow in other strains. Nevertheless, the essential facts I have mentioned apply to the vast majority of transplantable tumours.

*Imperial Cancer Research Fund Lecture given at the Royal College of Surgeons of England on November 22.

Transplantation Technique

When tumour transplantation is practised merely as an adjunct to other studies which require that the life of a tumour be extended artificially over a series of generations of the host animal, a comparatively simple yet necessarily aseptic technique suffices. Small fragments may be cut from the parent tumour and introduced singly to the desired sites in new hosts by a wide-bore needle or trocar and cannula. Alternatively the tumour may be reduced to an emulsion by mincing with scissors or a special instrument, or pounding it with a pestle in a mortar. Saline or Ringer's solutions are used only when it is necessary to thin the emulsion so that it can be injected to special sites by means of a fine needle. The graft or emulsion is usually placed subcutaneously, but other sites are employed for special purposes.

For the purposes for which they were designed and continue to be used, these simple transplantation techniques have the merit of combining simplicity with adequacy. The tumour cells are transplanted to their new hosts with a minimum of delay, and by using finely divided emulsions similar amounts of tumour cells can be inoculated into each animal of a group.

Various arguments might be advanced to justify an attempt to develop more quantitative methods for special purposes. On the other hand, consideration of the nature of the phenomena involved when a portion of living tumour tissue is transplanted to a new host and the extent to which the rate of growth may vary might lead to the conclusion that transplantable tumours are unlikely to be amenable to quantitative investigation. In view of the many obvious practical difficulties that have to be faced I do not feel justified in speculating on the possible practical applications of non-existent methods. However, it would seem desirable to indicate my main purpose in attempting to approach the study of transplantable tumours from a quantitative viewpoint.

The Quantitative Point of View

Numerous authors, arguing from the existence of a number of carcinogenic viruses, have suggested that many mammalian tumours, if not all, may be of virus aetiology. Failure to demonstrate viruses in tumours which cannot be propagated except by transplantation has been attributed to technical limitations and low transmissibility of the virus

from tumour to normal cells. Many excuses for failure to transmit transplantable tumours with cell-free filtrates, or with preparations from which living cells cannot be excluded with certainty, could be advanced in the light of our present-day knowledge of viruses. All the carcinogenic viruses amenable to conventional techniques have, so to speak, been dragged out into daylight. Yet hypotheses invoking the existence of more elusive ones can be advanced and cannot be disproved experimentally. Thus even the most sceptical must admit that there is a virus problem in relation to cancer, if only in this form.

So far as transplantable tumours are concerned I do not think that any real progress can be made with this problem until an adequate foundation of quantitative data has been laid down. It is necessary to determine, for example, using a representative series of selected tumours, the relationship between the dose of living tumour cells inoculated and the rate at which a tumour is produced at the site of inoculation. It is also urgently necessary to discover to what extent tumour cells can survive under various environmental conditions *in vitro*. I believe that it is only against an adequate background of such knowledge that we can obtain evidence for or against the existence of carcinogenic viruses of low transmissibility to normal cells. The evidence for or against will inevitably emerge without being directly sought for if a sufficiently complete quantitative characterization of tumour transplantation phenomena becomes possible.

However, for the moment it does not seem to be necessary to aim directly along such lines at such a distant objective as complete resolution of the virus problem. Indeed, it would be foolish to do so, for there are many important things that we do not know about the nature of viruses, as current speculations indicate clearly enough (vide Bauer, 1949). There seem to be ways in which quantitative refinements might be usefully introduced into investigations in which transplantable tumours are employed. If quantitative methods can be developed to the point of practical usefulness we may be confident that some information will accumulate which will be relevant to the virus problem in cancer.

Essential Specifications

Let us consider the three essential specifications that must be complied with if adequate quantitative methods are to be realized.

1. The preparations of tumour cells used for inoculation must be sufficiently homogeneous to obviate significant variations in the number of viable cells in different samples of a given volume of any given dilution.

2. The viability of the cells must be maintained unaltered during the period elapsing between the preparation of the inoculum and the completion of inoculation. This is a minimum requirement. It is obvious that opportunities for the development of quantitative techniques will depend on the period of time over which the activity of a suspension remains constant within the limits of error of determination of its activity. Should it be possible to reduce these limits of error to a level at which comparative titrations would be worth while, preliminary titrations would be necessary in order to narrow the range of cell concentrations and limit the number of animals used in the test proper. However, such two-stage tests will remain impracticable until methods of long-term stabilization of cell viability become available.

3. The third essential requirement is a quantitative method of comparing the activities of different tumour preparations.

The first specification presents a relatively simple problem which has been satisfactorily solved for present needs. Some progress has been made in regard to the second, and it has become clear that the viability of tumour cells may be extended for longer periods than might be expected from *a priori* considerations. The third requirement, a method of quantitative estimation, presents extremely difficult problems, which must await the accumulation of enough experimental data, and I would like this opinion to be borne in mind when, a little later on, I indicate one possible approach to the problem.

So far as is possible, I am going to present the progress of attempts to meet these specifications in a chronological manner. As will be appreciated, technical limitations and the experimental findings resulted, several times, in marked deviations from the more logical course that is obvious in retrospect. For example, if equipment for phase microscopy had been available when the work started just two years ago, or when dextrose was adopted as an aid to low-temperature preservation, the course pursued might have been very different.

Tumour Survival in Frozen State

The greater part of the work has been carried out with a mouse sarcoma (C3H, R.T., Ludford) which arose by stromal transformation of a sporadic mammary carcinoma. However, the initial attempts to preserve tumour-cell suspensions in the frozen state were made with a similar sarcoma of the R III strain (Ludford and Barlow, 1945) This tumour grows luxuriantly when inoculated intraperitoneally in R III mice. If transplanted to subcutaneous sites in the heterozygous MRC/H strain, the sarcoma often undergoes regression after considerable development. With a view to genetic selection and purification of the MRC/H strain and study of the regression phenomenon it seemed desirable to establish frozen stocks of the R III sarcoma.

It has of course long been known that tumours will survive in the frozen state. Ehrlich discovered this, but no serious attempt at practical application was made until Breedis and Furth (1938) investigated the matter. These authors demonstrated that various tumours could be preserved in the frozen state on CO_2 ice (−79° C.), for periods up to 400 days. There is an extensive but scattered literature relating to the survival of unicellular and other primitive organisms and also of some mammalian cells on freezing and thawing. The subject, up to 1938, has been reviewed by Luyet and Gehenio (1938). Of more recent work, I would select for special mention the convincing work of Briggs and Jund (1944), who showed by transposed transplanting of dorsal and ventral autoplastic grafts that normal mouse skin will survive sufficiently for grafting purposes when frozen for 1 hour to 24 hours at −78° C. Webster (1944), reporting results with refrigerated human skin grafts, describes takes with grafts refrigerated to −72° C. and with a lyophilized graft—i.e., one dried from the frozen state *in vacuo*.

Nearly all the reported observations on tumour survival in the frozen state relate to portions of tumour preserved *en masse*. One might expect that separated tumour cells exposed to an artificial fluid environment are more likely to be killed by freezing than cells situated in the interior of an intact portion of tumour. This, in fact, was the finding of Mider and Morton (1939). It will be remembered that the first specification I have outlined was as follows: "The preparations of tumour cells used for inoculation must be sufficiently homogeneous to obviate significant variations in the number of viable cells in different samples of a given volume of any given dilution." Obviously, homogenization of tumour preparations must be carried out before distribution to ampoules and preservation by freezing

From the theoretical point of view the possibilities are not encouraging if we consider the probable fate of cells suspended in any of the physiological salt solutions. When a salt solution freezes, ice crystals separate and the concentration of salt in solution increases until the eutectic concentration is reached. This eutectic concentration does not freeze unless the temperature is reduced to a critical level. Consider the figures for the salts present in Ringer's solution: the eutectic mixture of KCl with water is 25% and its freezing-point is −10.7° C.; of NaCl, 30.4%, with a freezing-point of −21.2° C.; of $CaCl_2$, 48%, with a freezing point of −52° C. This means, for example, that if a cell suspension is frozen at a temperature above −20° C. in 34 volumes of 0.85% NaCl, the volume of concentrated salt solution formed will be approximately equal to that of the cells, and its concentration will be 30%. Freezing under such conditions is therefore equivalent to soaking the cells in strong brine.

Preparation of Tumour Suspensions

Preliminary tests carried out with the R III and C3H sarcomas showed that when the tumour mince was diluted with more than a few parts of saline or Ringer's solution marked inactivation occurred on freezing and thawing. Other tests in which C3H sarcoma cells were held at 0° C. in various concentrations of NaCl or held in isotonic concentration for several hours at temperatures above and below −21° C. (the eutectic temperature of NaCl) showed that the rate and degree of inactivation were undesirably high. It seemed reasonable, therefore, to investigate the effect of substituting a non-electrolyte. Comparative tests with dextrose and saline solutions showed that sarcoma suspensions frozen in the former were much more active on thawing than suspensions prepared in the latter from the same lots of tumour mince. The optimum concentration of dextrose appeared to lie between 5 and 10%, but its protective effect was evident at from 3 to 40% if the suspensions were frozen without delay.

At this stage it became apparent that a better method of preparing tumour suspensions was required. A satisfactory solution, in the form of a pressure mincer, has been described (Craigie, 1949a). The later models of this instrument have been made entirely of stainless steel. Each mincer is provided with a set of four sliding-fit plungers provided with uniform longitudinal grooves. The groove sizes are 0.5, 0.25, 0.125, and 0.0625 mm. According to the consistency of the tumour and degree of mincing required, one or two plungers are selected and loaded in the barrel after the tumour tissue has been inserted. A portion of the suspending fluid is placed above the plunger. The plunger is then forced down by means of the screw, and the tissue passes through the plunger grooves into the suspending fluid.

To return to the problems of preserving tumour suspensions in the frozen state, I might mention that Breedis (1942) found that mouse leukaemic cells are inactivated if frozen too quickly in the temperature range of 0 to −15° C. A similar effect could not be demonstrated with the C3H sarcoma. This failure led to attempts to depress the freezing-point of suspensions in dextrose, one of which resulted in a striking demonstration of the survival of the C3H sarcoma under unexpected conditions. This has been reported (Craigie, 1949b), but the essentials are worth quoting.

C3H sarcoma mince was diluted to 1 in 12.5 (*a*) in 10% dextrose and (*b*) in 10% dextrose and 40% glycerol in water. Each suspension was distributed to several ampoules, sealed, frozen, and placed on CO_2 ice. The first test was carried out after the suspensions had been frozen for four days. Immediately after thawing, a portion of each was diluted with nine volumes of Ringer's solution. These dilutions, as well as the 1-in-12.5 concentrations, were injected subcutaneously in 0.1-ml. volumes, with the results shown in Table I.

TABLE I.—*C3H Sarcoma Suspension Frozen in Dilution of 1 in 12.5. 0.1 ml. Injected Subcutaneously after Thawing and Further Dilution*

Diluent	Time Frozen (Days)	Dilution Tested	No. of Tumours	Mean PMG (Days)
10% dextrose	4	1:12·5	6/6	8·0
	4	1:125	5/6	9·8
	253	1:17·5	12/12	4·17
	253	1:70	12/12	8·73
10% dextrose with 40% glycerol	4	1:12·5	6/6	11·0
	4	1:125	5/6	13·6
	253	1:17·5	12/12	4·08
	253	1:70	12/12	7·08

PMG = Period of microscopic growth, i.e., between inoculation and first appearance of tumour.

The preparation containing glycerol and dextrose appeared to be less active than the control. However, this may have been due to imperfectly developed technique and the use of Ringer's solution as a diluting fluid. A further test was undertaken after the preparations had been kept frozen for 253 days (Table I). In this test the dilutions were prepared in a saline–phosphate–cysteine mixture. As pointed out in the previous commentary on this experiment (Craigie, 1949b) the results, interpreted as being due entirely to the survival of tumour cells, indicate that at least 25% of the cells viable in the tumour mince before treatment survived dilution with 10% dextrose and 40% glycerol, freezing, preservation in the frozen state for 253 days, and subsequent thawing. In the light of more adequate data on the activity of freshly prepared C3H sarcoma-cell suspensions, this estimate seems to be confirmed. It is interesting to note that Polge, Smith, and Parkes (1949) have recently reported that glycerol protects spermatozoa against low temperatures. Fowl semen diluted with Ringer's solution showed no significant survival of spermatozoa after vitrification at −79° C. for 20 minutes and rapid thawing. On the other hand, the addition of 40% glycerol before freezing resulted in the resumption of full motility after thawing.

Effect of Dehydration

The preliminary results of the experiment with C3H sarcoma in dextrose and glycerol that I have quoted led to the adoption of drying techniques as a possible aid to the study of tumour survival on freezing, for the question of the role of dehydration by the suspending fluid inevitably arose. If dehydration were a factor, progressive loss of intracellular water at the low temperature of storage might be important. A few tests were carried out in which suspensions frozen in saline and in 5% dextrose were exposed to dehydrating agents *in vacuo* at −79° C. As expected, dehydration was extremely slow and further investigations were transferred from the CO_2 ice-box to the laboratory bench. It was planned to compare the effect of dehydration of tumour suspensions held in the frozen state at temperatures chosen in relation to the eutectic temperatures of Ringer's salts.

It might be noted that among the side-issues encountered during the development of equipment was the appearance of crystalline water-soluble and other organic substances in the water condensate. Back diffusion of pump oil was excluded, and the explanation seems to be that significant amounts of dried material from necrotic portions of tumour

were carried across in a microscopic state of division on the rapid current of water vapour. Tests of dried material obtained at various times during the development of the drying equipment (Craigie, 1949c) were negative, although one positive result was obtained later with C3H sarcoma and others were obtained by Gye, Begg, Mann, and Craigie (1949). On mature consideration of the problems involved it was decided to return to a study of the conditions of survival of activity of tumour suspensions on freezing, because freezing is the first step in freeze-drying. The need for quantitative methods also appeared to be urgent.

Degree of Survival

It had been found that a number of transplantable sarcomas and carcinomas could be preserved as suspensions in dextrose in the frozen state (Craigie, 1949b). In order to find out if primary chemically induced tumours would survive this treatment, groups of C3H mice of different ages were injected subcutaneously with 0.1% benzpyrene in arachis oil. A series of 19 tumours were removed at intervals ranging between 90 and 163 days from the injection and frozen in 5% dextrose in dilutions of 1 in 5 to 1 in 10. These were tested after being kept frozen for periods ranging from 36 to 96 days, and tumours were obtained in 17 of the preserved lots. (One other lot, diluted to 1 in 50 before freezing, failed to survive.)

It is evident from the results of this experiment that the degree of survival of the different tumours varied considerably. Some lots produced tumours at all sites injected, others at only some. The intervals elapsing between injection and appearance of the tumours ranged from 10 to 58 days. This variability in ability to survive freezing was also apparent in records of observations of other tumours. Although sporadic mammary carcinomas survive reasonably well, the best and most consistent survival has been obtained with tumours with a long history of transplantation. Sarcomas seem to be more resistant than carcinomas. Complete failure to survive freezing has been observed so far only with the two benzpyrene tumours mentioned and an undifferentiated tumour derived by Dr. Foulds from a squamous mammary tumour arising near the point of needle entry of intraperitoneal injection of methylcholanthrene.

From data which I shall present later it will be apparent that comparisons of activities of treated tumour preparations on the basis of percentages of tumours induced are of very doubtful validity. It cannot be too strongly emphasized that when suspensions of the C3H sarcoma are reduced by dilution or other means to a level of activity at which tumours fail to develop in 25% or more of the sites inoculated with a 0.1-ml. dose, the estimated order of survival is not more than one cell out of 100,000 or more cells viable in 0.1 ml. of the source tumour. The fallacy of comparing results on the basis of percentage of tumours obtained was not appreciated at first. In fact, until a year ago, attempts to obtain quantitative data on the survival of C3H sarcoma cells in various environments were based on the injection of a series of secondary dilutions with the object of identifying that giving 50% tumours. By way of excuse I might mention that titrations permitting observation or estimation of the 50% end-point are an integral part of modern and statistically acceptable methods used in exact work with pathogenic bacteria, viruses, and substances having an immunological or pharmacological action.

Fortunately, instead of recording the presence and size of tumours at weekly intervals, as is often practised with transplantable tumours, all mice were inspected daily and adequate records were available for analysis from experiments in which two to four dilutions or preparations were compared, not in different animals but at different sites in each member of a group. This is what emerged from an earlier experiment carried out with C3H sarcoma frozen in a dilution of 1 in 2.5 in (*a*) 5% dextrose and (*b*) 5% dextrose with M/150 phosphate buffer for four days. On thawing, dilutions were made in Ringer's solution to which 0.1% cysteine hydrochloride neutralized with phosphate had been added. Starting with the highest dilutions, two dilutions of each preparation were injected subcutaneously in 0.1-ml volumes in four groups of mice. The injections were deposited in the centres of the four abdominal quadrants; thus four comparisons were made in each mouse. When on later analysis the log of the dilution injected was plotted against the mean interval in days which elapsed before the tumour first became visible the picture shown in Fig. 1 was obtained.

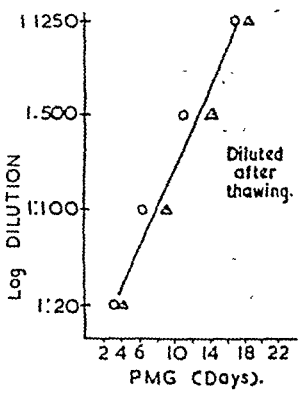

FIG. 1.—C3H sarcoma frozen with 1.5 parts of 5% dextrose (circles) and 5% dextrose and M/150 phosphate buffer (triangles).

This semi-logarithmic relationship suggests that any mean lag period* which may have intervened between inoculation and resumption of cell growth and mitosis was constant for all dilutions in this experiment and that the interval elapsing before the tumours became visible was primarily dependent on the volume of viable cells inoculated and the constancy of the average period between successive mitoses. There is reasonable agreement with the formulae :

$$T = L + \frac{m}{\log 2} \cdot \log \frac{1}{C},$$

$$\text{and } T_2 - T_1 = \frac{m}{\log 2} \cdot \log \frac{C_1}{C_2},$$

where T is the observed PMG value*; L, the lag period. m, the mean interval between successive mitoses; and C the concentration of viable tumour cells inoculated.

Of course, these formulae must not be taken too seriously at present. Things are not as simple as they might suggest, but it is of interest that sometimes they fit experimental results with astonishing accuracy for dilutions ranging from 1 in 50 to 1 in 1,000, and, further, that the value of "m," the mean interval between successive mitoses estimated from pairs of dilutions, has shown a remarkable constancy with unfrozen preparations. The formulae have proved useful in the analysis of experimental data because any statistically significant departures indicate that the simple, almost naive, assumptions involved are invalid on these occasions or that other factors, neglected in the formulae, have operated to a significant extent.

For example, tests checked with these formulae confirmed earlier suspicions about the inadequacy of Ringer's solution as a suspending fluid for tumour cells. However, before proceeding to discuss this, let me mention two rather striking and puzzling features about the development of tumours obtained with tumour-cell suspensions.

*The term "lag period" has been used in a different sense (Craigie, 1949b). Since lag period must be redefined as above, the abbreviation PMG (period of microscopic growth) is suggested to denote the time interval between the end of the lag period and the appearance of visible growth.

Rate of Growth

In the mouse a subcutaneous injection of 0.1 ml. spreads to occupy a visible area more than 1 cm. in diameter. It might therefore be expected that several discrete tumours would appear when multiples of the minimal tumour-inducing dose are given. This is rarely so. In fact, the only striking development of multiple tumours that has been encountered occurred with suspensions frozen with glycerol and dextrose. The second point is this: after a tumour has made its first appearance its growth rate is far from constant. The daily increments in diameter are quite erratic; after remaining practically stationary for several days a definite increase may occur within 24 hours. Following subcutaneous injection of a suspension of a rapidly growing sarcoma, tumours make their first appearance (*a*) as a somewhat irregular subcutaneous mass, or (*b*) as a nodule in the deeper layers of the dermis, or (*c*) as a muscle-plaque. When first recognized the tumours are nearly always 1 to 2 mm. in diameter, or larger. They may appear within six hours. Thus there is at first sight a somewhat puzzling inconsistency between the sudden appearance of tumours and their frequent apparent quiescence for several days after they appear. Further, any attempt to base quantitative estimates on recorded dates of first appearance might seem to be a very questionable proceeding.

However, it must be borne in mind that if these tumours grew at a uniform rate around the time of the first appearance it would be very difficult to be certain on which day they first appeared. Actually there is no difficulty in ascertaining the date of first appearance. (I should add that a very small percentage disappear in 24 or 48 hours, in which event the record is cancelled.) It is evident that a detailed histological investigation of inoculated sites will have to be undertaken. However, adequate trial has shown empirically that data based on the times of first appearance of tumours induced by the inoculation of cell suspensions into 16 sites or more are much more likely to serve as a useful basis for quantitative comparisons than observations which record only the percentages of tumours obtained.

When it was found that dextrose was of value for preserving tumours in the frozen state, tests were undertaken to determine whether it was a desirable fluid for preparing dilutions of fresh or frozen and thawed suspensions for inoculation. It appeared to be somewhat inferior to salt solutions. Further observations were made from time to time, and the results can be summarized briefly. If dilutions are injected immediately they are prepared, physiological saline, saline with phosphate buffer, with or without cysteine, and Ringer's solution are definitely better than 5% dextrose. If there is a delay before injection of frozen and thawed preparations activity is reduced in all these solutions and the higher the dilution the greater the rate of inactivation. The need for a more satisfactory diluting fluid was emphasized by the tantalizing glimpses of tumour cells conforming to the simple and rational quantitative law suggested in Fig. 1. A further retreat was indicated and, in conformity with the principle that first things should come first, attention was concentrated on the survival of fresh unfrozen sarcoma cells.

When a C3H sarcoma is minced and series of dilutions from 1 in 50 to 1 in 1,000 are prepared in Ringer's solution and inoculated immediately, results illustrated by those shown in Fig. 2 are obtained. As in Fig. 1, a semi-logarithmic relationship between dose and mean time of appearance (PMG) of the tumours is strongly suggested. The curves on the left and right of Fig. 2 were obtained with healthy and necrotic tissue from the same tumour. The apparent discrepancy between these curves may be entirely referable to a less adequate dispersion of viable cells from the firmer healthy tissue, since the titration was carried out 10 months ago, using an earlier and less efficient model of pressure mincer. Another point to be noted is that the slope of the lines may be interpreted as a function of the mean interval between successive mitoses. If this is correct it may be calculated that 0.1 ml. of a 1-in-1,000,000 dilution of C3H sarcoma would produce tumours around

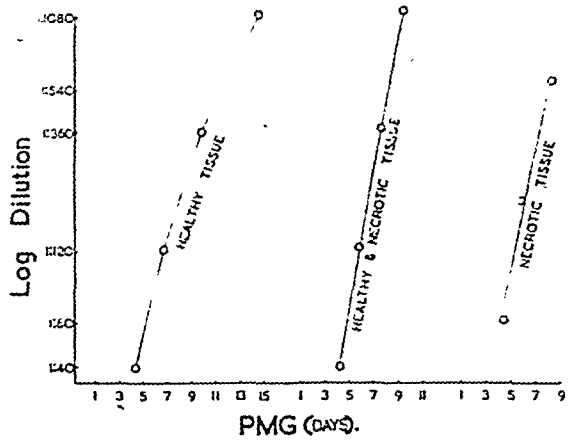

FIG. 2.—C3H sarcoma-cell suspension titrated in Ringer's solution.

21 days after inoculation, provided that the cells remain viable in such high dilutions and the majority of single cells are capable of initiating tumours. However, this expectation cannot be realized.

Beyond a dilution of 1 in 1,000 there is a marked departure from the reasonably consistent relationship of log dose and mean PMG value observed with stronger concentrations. As the dilution is increased the percentage of tumours obtained falls off rapidly and their appearance is delayed. There are two possible interpretations. The minimal number of local concentrations of viable cells required to initiate a tumour in 75% of instances may be very large. Alternatively, Ringer's solution may exert a toxic effect when some unknown protective substance derived from the tumour tissue is diluted beyond an effective concentration.

A Different Approach

Attempts to increase the activity and stability of dilutions beyond 1 in 1,000 by the addition of tumour or muscle extracts or homologous blood and serum were unsuccessful. After reviewing the composition and history of the physiological salt solutions and fluids used to promote the survival of specialized cells it was decided to try a different approach. The differential balance of cations and anions across the limiting membrane of the living cell is such a fundamental fact that it is generally assumed that it must be maintained within reasonable limits if the cell is to survive. However, we must not confuse "survival" with maintenance of metabolic and functional activity. Suppose we could match the inorganic substances present inside the cell, ion for ion, across the cell membrane, would the effects be worth observing? Unfortunately, no complete figures for the composition of the intracellular fluid of tumour cells is available. The average figures for muscle tissue given by Muntwyler and Mautz (1947) have had to be used as a guide.

A preliminary investigation has been made of the survival of C3H sarcoma in fluids containing Na, K, Mg, and P in the same amounts as given in Fig. 3 for the intracellular

phase of muscle. These fluids are isotonic and adjusted to *p*H 7.3. It is hardly necessary to point out that precipitation of magnesium phosphate must be avoided in preparing them. There are obviously many organic substances which might be used to adjust the base balance, but trial has been limited to fluids containing lactate or succinate ions. In some tests the amount of organic anion has been reduced by the inclusion of carbonate, but this creates

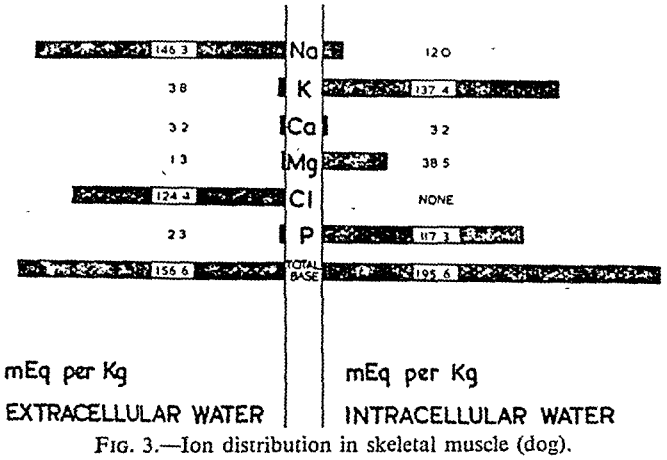

FIG. 3.—Ion distribution in skeletal muscle (dog).

difficulties in maintaining a constant *p*H. The succinate system has yielded more striking results than the lactate system.

Before quoting some experimental results I would like to mention two interesting points about the stability of these fluids. If the succinate system is heated to 48° C. it becomes turbid, and at higher temperatures a precipitate forms. If it is frozen and then thawed quickly it remains clear, but if it is thawed slowly a precipitate is obtained. However, precipitation on slow thawing is prevented if 2.5% or more of dextrose is added before freezing. The limited range of stability of this fluid is referable to the low solubility of magnesium phosphate and the solubility products of the various possible combinations of cations and anions in the mixture. The properties of this fluid, which is intended to resemble intracellular fluid in respect of balance of inorganic ions, invite speculation on the primary mechanisms of cell death on freezing and thawing and on exposure to the minimal lethal temperature.

Artificial Intracellular Fluid

Fig. 4 shows the results of a comparison of the survivals of C3H sarcoma cells in Ringer's solution and artificial intracellular fluid (A.I.C.F.) with succinate. A 1-in-5 suspension of sarcoma cells was prepared in 5% dextrose. This was diluted 1 in 10 and 1 in 50 (i.e., to 1 in 50 and 1 in 250) in (*a*) Ringer's solution and (*b*) A.I.C.F. The diluted suspensions were distributed to ampoules, which were sealed and kept in ice-water. Tests were carried out at two hours and after three, six, and eight days at 0° C. On each occasion each of the suspensions, in 0.1-ml. volumes, was injected subcutaneously in 16 mice. Four ventral sites were used in each mouse, one for each preparation, and the positions of the preparations were rotated to cancel out site variations. The date of first appearance of each tumour obtained is shown in Fig. 4.

The greater degree of survival in the succinate A.I.C.F. is obvious. It is also evident that the survival in the 1-in-250 dilutions is much shorter than that obtained with the 1-in-50 dilutions. It should be noted that both the Ringer and A.I.C F suspensions contained 0.5% dextrose carried over from the primary suspension.

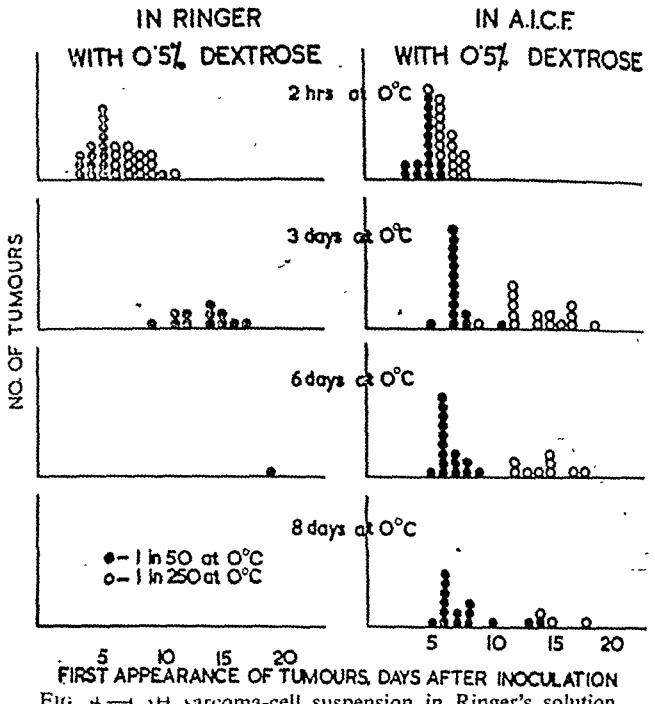

FIG. 4.—C3H sarcoma-cell suspension in Ringer's solution and A.I.C.F.

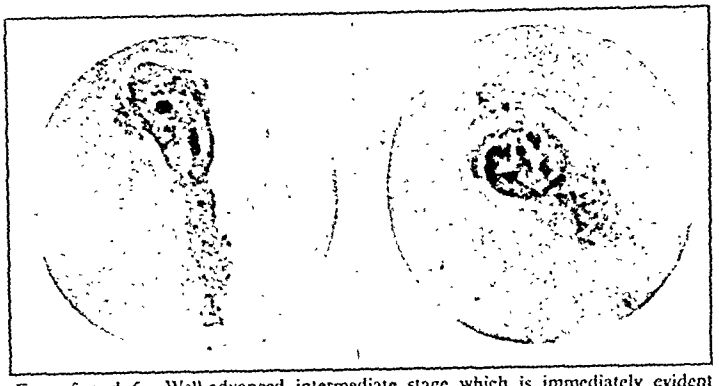
The superiority of succinate A.I.C.F. as a preserving fluid for sarcoma cells at 0° C. over Ringer's and Tyrode's solutions has been confirmed in a number of experiments. Significant survival up to 15 days has been observed.

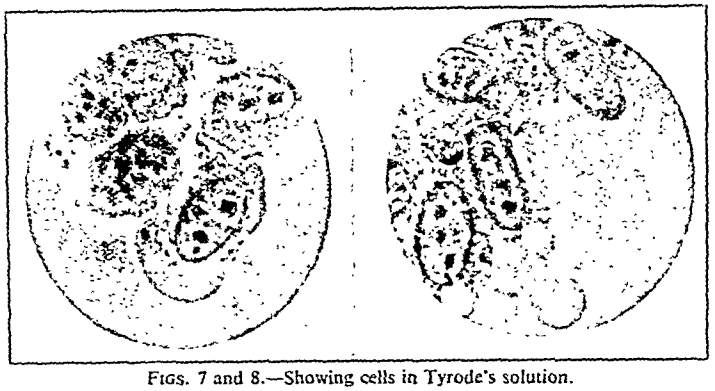
TABLE II.—*C3H Sarcoma Cell Suspension Held in Succinate A.I.C.F. at 0° C. in a Dilution of 1 in 63*

Time Held at 0° C. Before Inoculation	No. of Sites Injected	Total No. of Tumours	Date of First Appearance of Tumours (Days After Inoculation)									
			2	3	4	5	6	7	8	9	10	11
3 days	12	12	0	0	9	1	1	0	0	0	0	1
9 ,,	16	16	0	0	4	8	3	1	0	0	0	0
15 ,,	16	16	0	0	0	3	9	3	1	0	0	0



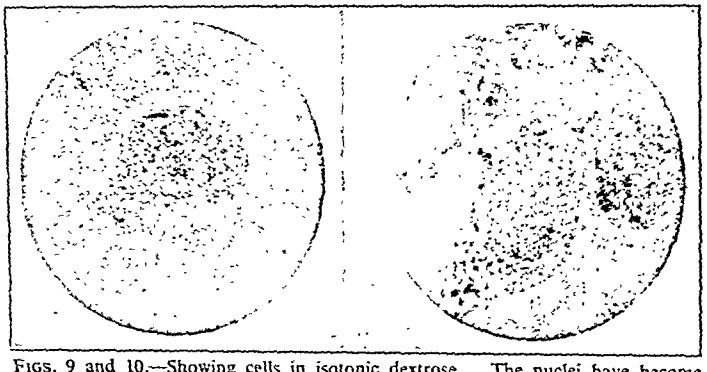
The results shown in Table II are taken from an experiment carried out to obtain data on the influence of Na and Mg ions. Only the results obtained with Na, K, and Mg in the proportions shown in Fig. 3 are shown. A considerable degree of survival (20 to 25%) occurred up to 15 days at 0° C. In this experiment no evidence that Na is essential to survival was obtained, but in the absence of Mg deterioration was rapid.

As a working hypothesis it might be assumed for the present that survival in A.I.C.F. is referable to abolition of the normal ion differential across the cell membrane and consequent depression of certain phases of cell metabolism. It might therefore be suggested that comparative studies of the survival of tumour cells in fluids of this type, in which the concentration of the inorganic ions and the nature of the supplementary organic base are varied, might provide an indirect approach to some cytochemical problems. Before leaving the subject of A.I.C.F. I might remark that if one wished to transmit an extremely labile virus from one cell to another it would be reasonable to guard it from the shocks of change in ionic environment. Some difficult mammalian viruses might be easier to handle in fluid which approximates in inorganic ion balance to the fluid in which they multiply within the cell.



Nuclear and Cytoplasmic Changes

There is one further topic to which reference must be made—namely, the nuclear and cytoplasmic changes



induced in tumour cells by the treatments I have mentioned. It has become essential to have an adequate record of the appearance of the cells in all suspensions tested by mouse inoculation. The routine which has been recently adopted is as follows. A portion of the suspension remaining in the syringe after injections are given is transferred to a cytometer slide. A number of fields are systematically recorded at a low magnification on fine-grain 35-mm. film of fixed contrast (Micro-Neg, Ilford) using phase contrast illumination. The phase-contrast photomicrographs of C3H sarcoma cells here shown will, I hope, make it obvious that detailed cytological studies are required in order to establish criteria of cell death under various conditions. As will be seen, nuclear and cytoplasmic detail is profoundly influenced by the fluid in which the cells are suspended. The photomicrographs were obtained from freshly prepared suspensions made from the same lot of C3H sarcoma mince. The photographic processing was strictly standardized, so that differences in contrast are comparable.

FIGS. 5 and 6.—Well-advanced intermediate stage which is immediately evident when C3H sarcoma cells are suspended in A.I.C.F.

FIGS. 7 and 8.—Showing cells in Tyrode's solution.

FIGS. 9 and 10.—Showing cells in isotonic dextrose. The nuclei have become swollen and are hyaline and vitreous in appearance.

Zollinger (1948) states that the brilliant type of nucleus, with bright nucleoli and double-contoured nuclear membrane, is a reliable sign of cell death, but there are grounds for doubt. When C3H sarcoma cells are suspended in A.I.C.F. a well-advanced intermediate stage is immediately evident (Figs. 5 and 6). Potocytosis (blistering proceeding to liberation of spherules of cytoplasmic fluid) seems to be a normal reaction of these cells to saline, Ringer's and Tyrode's solutions (Figs. 7 and 8, cells in Tyrode's solution), but it is very rarely seen in isotonic A.I.C.F. The effect of dextrose—a rapid disappearance of nucleoli and associated chromatin—has been described briefly (Craigie, 1949b). The nuclei, within a few seconds of contact of the cell with isotonic dextrose, become swollen and are hyaline and vitreous in appearance (Figs. 9 and 10).

Conclusion

In concluding this lecture I would like to emphasize that no certain evidence of the existence of a virus or transmissible agent, other than the Bittner agent, associated with transplantable mouse tumours is likely to emerge in the absence of adequate quantitative knowledge concerning the biomechanics of tumour-cell transplantation and the ability of the cells to survive under various conditions. The initial rather vague belief with which this work started has crystallized into the conviction I have expressed. There is a great deal that we do not know about the response of tumour cells to various artificial environments and the conditions necessary for their survival. There are some odd things about the way in which tumours appear after inoculation of tumour-cell suspensions that suggest the desirability of detailed histological examination of the inoculated sites. I, for one, when examining unfixed and unstained tumour cells under the phase microscope am often uncertain whether they are alive or dead. These problems may be approached in various ways, but they should, I think, be studied together and every endeavour made to place the observations on a quantitative basis so far as the materials permit.

ANTICOAGULANT THERAPY*

BY

H. W. FULLERTON, M.A., M.D., F.R.C.P.

AND

G. ANASTASOPOULOS, M.D.Athens

(From the Department of Medicine, University of Aberdeen)

There is little disagreement about the value of heparin in the prophylaxis and treatment of thrombosis, and considerable quantities of this expensive drug are now used. The control of the dosage, however, often seems to be unsatisfactory, and we feel that more would be gained by giving larger and fully effective doses to a smaller number of carefully selected cases. The aim should be to maintain the clotting time at about 30 minutes instead of the normal 6–10 minutes, and this seems seldom to be achieved by the usual practice of intravenous injections of 50–75 mg. four-hourly. It is probably more efficacious to give a continuous intravenous drip of heparin in saline (say 100 mg. per pint, or 175 mg. per litre) at a rate of 15 to 25 drops a minute, the rate being adjusted at intervals so as to maintain the desired prolongation of coagulation. But until we have available effective preparations of heparin with an action lasting many hours when given intramuscularly it is unlikely that this drug will be employed for more than a few days at a time, and in the great majority of cases of thrombosis effective treatment for much longer than this is desired.

Dicoumarol

This brings us to consider dicoumarol, which is given orally and is thought to prevent the development or extension of thrombosis by lowering the prothrombin and thereby the coagulability of blood and we propose to confine the rest of the paper to a consideration of this drug, which is now widely used in the treatment of many forms of venous and arterial thrombosis.

Dicoumarol has not proved to be one of those drugs which fade into disuse after a short period of popularity. Rather the reverse is true, and as time has passed and more and more reports have appeared its place in the treatment of thrombosis has become more firmly established. It is true, of course, that many of these reports have dealt with such small numbers of cases that their value has been negligible, but several large and well-controlled series have been published, and these are impressive enough to justify its use. A committee of the American Heart Association has recently reported the results in 800 cases of coronary thrombosis (Wright *et al.*, 1948). Of these, 368 patients admitted on even days received conventional treatment without anticoagulants; and 432 admitted on odd days were given the same conventional treatment with the addition of anticoagulants, mainly dicoumarol. While the mortality rate in the control group was 24%, in the treated group it was 14.9%, and this reduction was accounted for mainly by the much smaller number of deaths after one or more thrombo-embolic complications in the treated group.

More than 25% of the control group developed one or more thrombo-embolic complications, as compared with about 12% in the treated group. Moreover, in only about 6% did these complications occur at a time when the anticoagulant therapy could reasonably be expected to be effective.

*Read in the Section of Medicine at the Annual Meeting of the British Medical Association, Harrogate, 1949.

The incidence of the various thrombo-embolic complications was noted, and it was found that for extensions of the original infarct, for new infarctions, for pulmonary, cerebral, and peripheral emboli, and for venous thromboses the incidence was notably less in the treated group.

These results provide striking confirmation of the effectiveness of dicoumarol as an anticoagulant and are likely to increase its use in coronary thrombosis considerably The results of its use in venous thrombosis are also striking, although frequently the findings have not been so well controlled

Unfortunately two considerations have to be borne in mind before a decision to use it as a routine can be adopted First, no uniform scheme of dosage can be prescribed, because of the marked individual variation in response Secondly, dosage must be carefully controlled, because not infrequently a haemorrhagic tendency, which may be severe, complicates treatment. This is often due to too great lowering of the prothrombin level of the blood Accordingly, dosage in each case must be controlled by regular estimations of plasma prothrombin—ideally every day, certainly not less often than every second day. In our opinion this consideration should limit the use of dicoumarol to patients in hospitals with adequate facilities for these tests. Even in these circumstances haemorrhage —e.g., severe haematuria—will occasionally occur. Without such careful control one of two things is likely to happen: either small ineffective doses will be used or effective doses will lead to some disastrous haemorrhages

On the question of what test should be used to control the dosage there has been much difference of opinion and confusion of thought. It is now possible to clear away some of the misconceptions which have arisen in the past few years and therefore to understand better the significance of the different techniques of so-called "prothrombin estimation." Certainly the lack of knowledge concerning these techniques and the resulting confusion have prevented dicoumarol being used on a much wider scale.

The simplest theory of blood coagulation is that of Morawitz, who describes the process as occurring in two steps: (1) thrombokinase + prothrombin + calcium → thrombin; (2) thrombin + fibrinogen → fibrin. It used to be thought that thrombokinase was derived mainly from disintegrating platelets in shed blood and from tissue cells damaged in a wound; now its main source is believed by some to be a precursor in the plasma (Lozner *et al.*, 1942) According to this theory it converts prothrombin to thrombin in the presence of free calcium ions. When enough thrombin has accumulated the soluble protein fibrinogen is converted to strands of fibrin which contain the red cells and serum in their meshes.

Prothrombin Estimation

(*a*) *Quick's Method.*—This is based on the above theory, and is widely used in America and this country in the control of treatment with dicoumarol. In this method the source of thrombokinase is a suspension of acetone-dried rabbit brain. A similar substance can be obtained from most tissues—e.g., several workers have used an extract of lung, and now human brain is widely employed.

The essential steps in the test are: (1) 4.5 ml. of blood is mixed with 0.5 ml. of oxalate solution. The calcium is thereby removed and development of Stage 1 is prevented. (2) To 0.1 ml. of plasma the same volume of brain-powder suspension is added—the tube being held in a water bath at 37° C. (3) Then 0.1 ml. of calcium solution is added

quickly and the time between this addition and the formation of fibrin is noted, a stopwatch being used.

This is the so-called "prothrombin time." The theoretical justification for regarding this time as an indication of the prothrombin content of the plasma is that when optimal amounts of thrombokinase and calcium are added the only variable in Stage 1 is the amount of prothrombin. Therefore the smaller the amount of prothrombin the longer the time before enough thrombin is formed to bring about Stage 2.

Various workers have found different times with Quick's method in normal plasmas, usually ranging between 15 and 30 seconds. This is because different batches of brain extract vary in potency, and the normal time for each batch must be carefully determined before the test is used in patients. Moreover, the preparation of the powder is tedious.

(*b*) *Russell Viper Venom.*—The foregoing considerations led one of us (H.W.F.) to suggest the use of Russell viper venom as the source of thrombokinase in this test (Fullerton, 1940). Six years earlier Macfarlane and Barnett (1934) had investigated the possibilities of this substance in their search for a local haemostatic effective in haemophilia. They found that the venom was capable of accelerating the clotting of haemophilic blood in dilutions of 1 in 10^{12} or more. It did not clot oxalated or citrated blood unless calcium was added, and it did not clot solutions of fibrinogen. Accordingly, its action was that of a powerful thrombokinase.

As a result of this work Russell viper venom was produced commercially. The best-known preparation is "stypven" (B.W. and Co.): 0.1 mg. of dried venom and 1 ml. of distilled water are supplied in separate ampoules and the solution is made shortly before use. Different batches differ little in potency, and with normal plasmas "prothrombin times" of 18–25 seconds are usually obtained; consequently the careful standardization of each batch is unnecessary. Apart from this difference in the source of thrombokinase the technique is the same as Quick's.

(*c*) *Venom plus Lecithin.*—The venom method was quickly followed by a third. Witts and Hobson (1940) described a series of observations in which they used a mixture of venom solution and ovo-lecithin as the thrombokinase. Normal plasmas gave very short "prothrombin times" of 6–10 seconds, so it is evident that some substance in the ovo-lecithin potentiates the action of the venom. Witts and Hobson, and recently Biggs and Macfarlane (1949), added an alcoholic solution of lecithin to the venom. With this method we have had variable results. We believe that it is much more satisfactory to use water instead of alcohol as the solvent. When ovo-lecithin is dissolved in water containing 0.5% phenol the solution retains its full activity for several months. This solution is added to a freshly opened ampoule of venom in the usual proportion (1 ml. to 0.1 mg. venom). With this modification the method is therefore a very simple one to use. With it we have not observed the marked day-to-day variations recorded by Biggs and Macfarlane during treatment with dicoumarol, nor have we found it insensitive as an indication of the effects of this drug; in fact, definite prolongation of the time has usually been observed on the second or third day of treatment—i.e., at the same time as changes occur when brain powder is used.

The questions then arise: How do these three methods compare? Do they measure the same factor when they are used to control the dosage of dicoumarin, or is one to be preferred to the others when it is used in this way? These questions can be answered satisfactorily if we base our deductions on a theory of coagulation slightly different from that of Morawitz.

Role of the Lipoid Factor

There seems no doubt that a lipoid substance is essential for the coagulation of blood. For example, Macfarlane *et al.* (1941) have shown that oxalated plasma from which the fat has been removed by high-speed centrifuging or by extraction with carbon tetrachloride will not clot after the addition of a fat-free thrombokinase such as viper venom and calcium unless some lipoid material like ovo-lecithin or cream is added as well. We believe that it is not only essential in the first stage of coagulation but that it is a separate and distinct substance—in a way similar to calcium but with the difference that while it is simple to free a plasma of the calcium ions without disturbing the other factors concerned in coagulation it is very difficult to free it entirely of the lipoid substance. Moreover, alterations probably occur in the concentration of this lipoid factor in the plasma of a degree sufficient to alter the coagulability of blood.

If we accept this theory then the following is clear:

(1) That with the venom+lecithin method optimal amounts of thrombokinase and the lipoid activator are added in the test. Therefore this method measures the prothrombin level but will not reveal alterations in coagulability due to variations in the plasma level of the lipoid factor.

(2) Brain extract contains optimal amounts of lipoid factor and variable and suboptimal amounts of thrombokinase. The results of a representative experiment illustrate this point (Table I). All the estimations were made in one sample of plasma. With venom alone an average time of 22.5 seconds was obtained. With the particular batch of brain we were then using the time was 24.1 seconds; with venom+lecithin it was 9.3 seconds. Adding ovo-lecithin to the suspension of the brain powder produced no shortening of the time: this indicates that the brain extract already contained an optimal amount of the lipoid factor. But the addition of venom (0.1 mg. per ml.) to the brain suspension reduced the time to 10.8 seconds, which is not significantly longer than the result with venom+lecithin (9.3 seconds). This indicates that the concentration of thrombokinase in the brain suspension is suboptimal.

TABLE I.—*Prothrombin Time with the Various Methods*

Thrombokinase	"Prothrombin Time"
Venom	22·5 secs.
Brain powder	24·1 "
Venom + Lecithin	9·3 "
Brain powder + Lecithin	25·4 "
Brain powder + Venom	10·8 "
Brain powder + Venom + Lecithin	10·2 "

We believe, therefore, that Quick's test, like the venom+lecithin method, measures prothrombin but not changes in coagulability due to variations in the lipoid factor. Since optimal concentrations of thrombokinase and the lipoid factor can be assured with the venom+lecithin method it would seem preferable to the brain extract method.

(3) When venom alone is used we have a thrombokinase which is free of lipoid factor. Accordingly, by this method the so-called "prothrombin time"—the "accelerated clotting time" is a better term—is an accurate measure of prothrombin only if the concentration of lipoid factor in the plasma is within the normal range. And, conversely, if the prothrombin is constant this test will measure variations in the lipoid factor in the plasma.

The justification for these statements and their practical importance is based on the following experimental work.

Effect of Alimentary Lipaemia

The effect of lipaemia on the coagulability of blood following a high-fat meal was determined by the "accelerated clotting time," venom being used as the thrombokinase.

When the ordinary ward meals are taken there is no significant variation in the accelerated clotting time throughout the day; this conclusion is based on a study of eight patients. But in a group of six patients given a breakfast containing 85 g. fat (bacon and eggs and bread-and-butter) the results were striking (Table II).

TABLE II

Fat Intake 85 g.				
Case	Fasting	During Lipaemia	Difference	Time of Shortest Reading After Meals
1	24·5 sec.	10·9 sec.	13·6 sec.	5 hours
2	22·3 ,,	13·4 ,,	8·6 ,,	4¾ ,,
3	23·0 ,,	12·8 ,,	10·2 ,,	3 ,,
4	24·3 ,,	17·5 ,,	6·8 ,,	2¼ ,,
5	22·3 ,,	14·8 ,,	8·0 ,,	3¼ ,,
6	24·7 ,,	13·1 ,,	11·6 ,,	3¾ ,,
Average ..	23·5 ,,	13·7 ,,	9·8 ,,	

In the second column is shown the accelerated clotting time in seconds with the patients fasting (average 23.5); in the third the shortest accelerated clotting time during the lipaemia (average 13.7 seconds); next the difference between the fasting and the shortest times (average 9.8 seconds); and lastly the time of the shortest reading in hours after the meal. In each patient a much shorter time was found at the height of the lipaemia.

Chart I shows the details in one case. The curve marked V represents the accelerated clotting times with venom as the thrombokinase falling from about 25 seconds fasting to 10.9 seconds at the height of the lipaemia. The line V+L was obtained by using venom and lecithin as the thrombokinase; it runs in a more or less horizontal line. The line R.B. was obtained by using rabbit brain extract; it too runs horizontally.

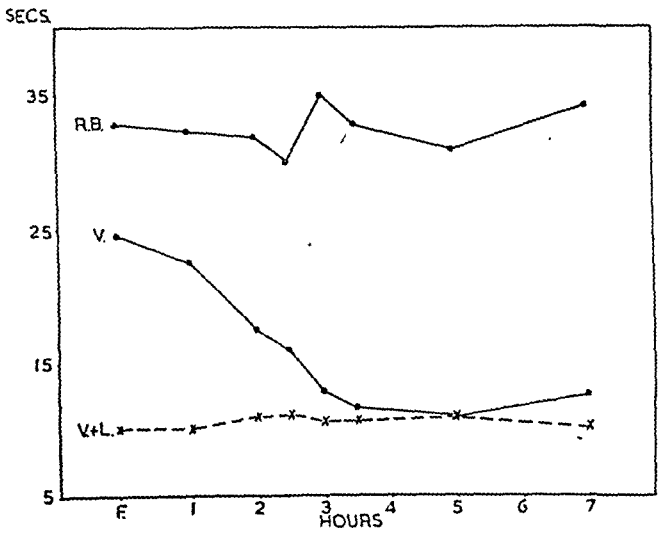

CHART I.—Accelerated clotting times in a patient after a meal containing 85 g. of fat.

Therefore we can conclude that accelerated clotting times determined by the use of venom show marked shortening during lipaemia, a result which is obscured by the use of venom+lecithin and of brain extract, because both these reagents contain an optimal amount of the lipoid factor essential for clotting.

Effect of Alimentary Lipaemia during Treatment with Dicoumarol

The next step was to investigate the effect of alimentary lipaemia in patients in whom dicoumarol treatment had produced a low prothrombin level. This was done in eight patients. The results varied according to the time after the start of dicoumarol treatment when the test was done and also according to the degree to which the prothrombin level had been depressed by the treatment. But it was very clear that the shortening of the accelerated clotting time produced by alimentary lipaemia was much less marked during dicoumarol treatment, and in some cases it was absent altogether.

One example will suffice (Chart II). The patient had received dicoumarol treatment for coronary thrombosis. The accelerated clotting time with venom with the patient fasting was 33.7 seconds. He then took the meal containing 85 g. fat, and at intervals of one hour, two hours, two and a half hours, three hours, and three and three-quarter hours thereafter the times were 32.9, 33.6, 32.6, 31.1, and 33.2 seconds: that is, there was no significant shortening after the meal. The venom+lecithin curve runs horizontally and the rabbit brain extract curve horizontally with some irregularity.

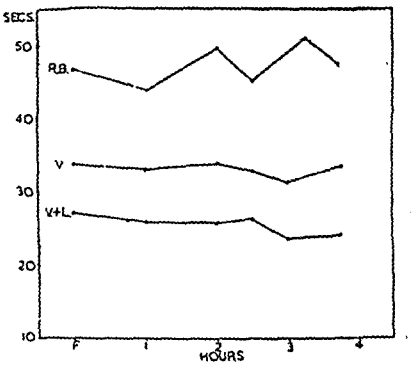

CHART II.—Accelerated clotting times in a patient undergoing dicoumarol treatment and after a meal containing 85 g. of fat.

We believe that the explanation for this striking difference is that when one component in the first stage of coagulation—viz., prothrombin—is depressed by dicoumarol a compensatory increase in another component—the lipoid factor—occurs and so lessens the reduction in coagulability produced by the drug. Alimentary lipaemia produces little or no shortening of the accelerated clotting time when the effects of dicoumarol are marked, because even in the fasting state the plasma level of the lipoid factor may be nearly optimal.

Further evidence in support of this theory is provided by comparing the results obtained by the use of the venom and the venom+lecithin tests throughout the period of dicoumarol treatment. Chart III illustrates the typical findings. Before treatment the accelerated clotting time with venom was 22 seconds; with venom+lecithin 10.5 seconds. Then 1,700 mg. dicoumarol was given over a period of seven days. Increases in the clotting times occurred with both methods, but the difference between the two became less, and it increased again as the effect of the dicoumarol passed off. We believe that this result is due to an increase in the lipoid activator in the plasma, which

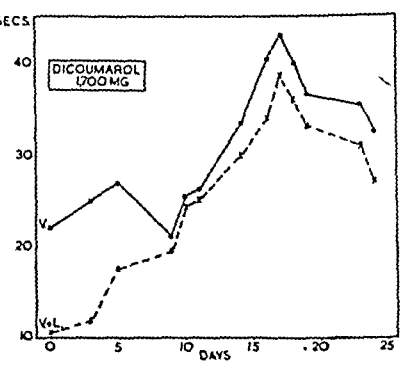

CHART III.—Typical findings when 1,700 mg. of dicoumarol was given for seven days.

after some time reaches nearly an optimal concentration. The effect of this is that the addition of lipoid factor to the venom—as in the venom + lecithin test—produces little or no potentiating action.

On the basis of these results it may be concluded that when dicoumarol is controlled by tests using venom + lecithin or brain extract a reasonably accurate assessment is obtained of the reduction in prothrombin produced by the treatment. But this reduction in prothrombin does not accurately represent the effect of dicoumarol on the coagulability of the blood, since an increase in lipoid factor follows the reduction in prothrombin. The test using venom alone reflects this alteration in coagulability, but does not accurately determine the reduction in prothrombin.

Effect of Haemolysis

One additional point of considerable practical importance is that slight haemolysis produces considerable shortening of the accelerated clotting time when the venom test is used, but not with the venom + lecithin and brain extract tests.

Chart IV illustrates this point. Haemolysed solutions were prepared by adding one volume of packed red cells

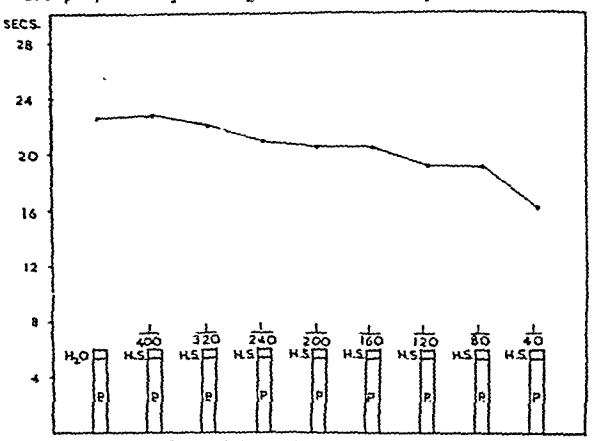

CHART IV.—The effect of haemolysis in shortening the accelerated clotting time with the venom test.

to different volumes of distilled water—one volume of cells in 400 of water, one in 320 of water, one in 240, and so on up to one in 40. One volume of the resulting solutions was then added to nine volumes of plasma, and as a control one volume of water was added to nine volumes of plasma. The accelerated clotting times using venom were then estimated in each, four determinations being made and the average taken. It is clearly seen that as the strength of the haemolysed solution increases the clotting time falls from the control level of 22.6 seconds to 16.1 seconds. We particularly wish to stress that in the range of haemolysed solutions used in this experiment the presence of haemolysis could be recognized macroscopically only at the right-hand end of the scale; in the last plasma slight but definite haemolysis was discernible; in the next a mere trace; in the next it was doubtful; and in the others haemolysis could not be detected.

It is clear, therefore, that when the venom test is used the greatest possible precautions must be taken to avoid haemolysis; the syringe must be dry and must be manipulated gently, and inversion of the tube to ensure mixing of blood and oxalate solution must be done very carefully.

Failure to appreciate the effect of haemolysis has been responsible for some of the confusing results reported. For example, recently there appeared an article by James (1949), who set out to compare the venom and the brain test in patients treated with dicoumarol. He used oxalate crystals instead of solution, and to ensure that they dissolved rapidly in the blood he shook each sample well. Obviously he was producing variable degrees of haemolysis, and accordingly his results with the venom test must be discounted.

The active agent in the red cells which produces this effect is probably the lipoid factor in the cell envelope; hence the effect is not seen with the venom + lecithin and brain extract tests.

Conclusion

Lastly the question arises, Which is the best test to use in the control of dicoumarol treatment? The answer is, I think, that it does not matter greatly which is used: the important points are to understand clearly the significance of the findings and to carry out the test with scrupulous attention to detail.

We use both the venom and the venom + lecithin method in each case. This entails very little extra work and the findings give important information. We aim to maintain the accelerated clotting times at about 25 seconds with the venom + lecithin test and at 35–40 seconds with the venom test—i.e., less prolongation proportionally with the latter. Prolongations of the time with the venom test require a larger dosage of dicoumarol and indicate a lower concentration of prothrombin than comparable prolongations with the venom + lecithin and brain tests. A failure to appreciate this point has caused much confusion and has been responsible for the view that the venom test is not suitable for the control of dicoumarol treatment. We do not express the results as a percentage of normal: this involves making unwarranted assumptions and confuses the picture. Until standard preparations of brain powder are obtainable we can see no theoretical advantage in using them. It would seem that their use is unlikely to give any more valuable information, but a careful comparison of the three tests has not yet been reported.

We give 300 mg of dicoumarol on the first day and 200 mg. on each of the two succeeding days. Further treatment is not given until the effect of these initial doses is seen, and then the dosage depends not only on the degree of prolongation of the accelerated clotting time but also on the speed with which this develops. No definite rules can be given; each case must be considered individually, and some experience is necessary before the desired prolongation can be attained and maintained. On several occasions haematuria has developed: we have used no special treatment for it apart from stopping dicoumarol, and no harm has resulted.

Summary

The value of heparin and dicoumarol is briefly appraised, and the difficulties of calculating accurate dosage are mentioned. Three methods of determining blood coagulability are described. The role of the lipoid factor in blood clotting is discussed from this standpoint. An account is given of experimental work showing the effect on the coagulability of the blood of lipaemia and haemolysis, and important points of technique in tests of blood coagulability are emphasized.

THE EXCRETION OF CHORIONIC GONADOTROPHIN BY PREGNANT DIABETICS

BY

J. A. LORAINE, M.B., Ch.B., Ph.D., M.R.C.P.Ed.

From the Medical Research Council's Clinical Endocrinology Research Unit, Edinburgh University

The quantitative estimation of chorionic gonadotrophin (C.G.) in the blood and urine of pregnant women has assumed new importance from the diagnostic point of view since the work of White (1937, 1943, 1946, 1947), White *et al.*, (1939), and White and Hunt (1943) on pregnancy complicated by diabetes and of Smith and Smith (1935, 1936, 1941, 1948), Watts and Adair (1943), and Smith, Smith, and Hurwitz (1944) on the toxaemias of pregnancy.

Although the introduction of insulin greatly reduced the maternal mortality rate in pregnant diabetics (Kramer, 1935; Lawrence and Oakley, 1942), the foetal mortality in such cases has not shown a corresponding decline (Herrick and Tillman, 1938; Gilbert and Dunlop, 1949; Barns and Morgans, 1949). It is evident that foetal wastage remains the great obstetrical problem in diabetes, and in some series of cases the foetal loss rate has been over 50%.

Set in this background, therefore, the great reduction in foetal mortality rate obtained by White (1946, 1947), using hormonal therapy in the form of oestrogens and progesterone in a proportion of these cases, is very striking indeed. Estimations were made by White of the serum chorionic gonadotrophin, using corpora lutea in immature female rats as the end-point of the biological assay: urinary pregnanediol was estimated by the Venning (1937) method and subsequently by that of Astwood and Jones (1941). A few assays of oestrogens in the serum were performed by biological methods.

From a study of 300 consecutive cases of pregnancy complicated by diabetes White (1947) found that such patients could be divided into two groups, each carrying an entirely different prognosis.

The first group consisted of 66 patients in whom the C.G. readings throughout pregnancy were classified as normal. In this group the foetal survival rate was 97%, the incidence of premature deliveries was 0, and that of pre-eclampsia 2%. The second group (over 75% of the 300 consecutive cases) was said to suffer from "hormonal imbalance" during pregnancy. The C.G. levels were abnormally high, and this finding was often associated with a low urinary pregnanediol and a low serum oestrogen. Of the patients in this group, 58 received no hormonal therapy and the foetal survival rate was only 47%; premature delivery occurred in 40% and pre-eclampsia in 50%. In addition many of these patients delivered babies which were grossly over weight.

Since this change in C.G. level preceded, often by some weeks, any obstetrical accident it was concluded that a rise in the serum C.G. could be regarded as the harbinger of an impending disaster. A group of 174 cases showing "hormonal imbalance" were treated with oestrogen and in most cases with progesterone as well. In these patients the foetal survival rate rose to 90%; premature delivery occurred in only 5%, pre-eclampsia in 5%, and the majority of patients receiving this treatment delivered babies of normal size.

method of assay of C.G. depending on the increase rostatic weight in immature rats and based on the use of the International Standard preparation of C.G. is described elsewhere (Loraine, 1949). This method was applied to the estimation of C.G. in the urine of normally pregnant women. In these normal cases very high readings, such as 25,000–30,000 i.u. of C.G. per 24 hours, were obtained from the 40th to the 80th day of pregnancy as calculated from the date of the last menstrual period. This was followed by a gradual decline, and from the 100th day until the end of pregnancy the excretion of C.G. was between 4,000 and 10,000 i.u. per 24 hours.

In Fig. 1 is shown the complete range of all the estimations made on the urines of normal pregnant women. The figures are quantitatively similar to those of Jones, Delfs, and Stran (1944), who also used the International Standard but estimated C.G. in the serum. Curves of the same general shape have been obtained by other workers, who expressed their results in arbitrary "rat units" (Cole and Saunders, 1935; Browne and Venning, 1936; Smith and Smith, 1936; Boycott and Rowlands, 1938; Browne, Henry, and Venning, 1939; Siegler, 1939; Rakoff, 1939; Taylor and Scadron, 1939; Venning, 1948). Although the series of cases was a relatively small one, the variations in the amount of C.G excreted per 24 hours during the second and third trimesters of pregnancy were smaller than has been generally supposed, and much of the apparent variation shown by previous workers has probably been due to the use of relatively inaccurate assay methods.

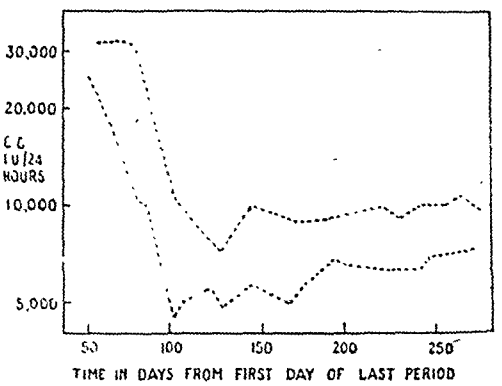

FIG. 1.—Total range of 136 estimates of the excretion of chorionic gonadotrophin in normal pregnancy.

The number of pregnant diabetics studied is as yet too small to assess adequately the effect of stilboestrol in reducing the foetal mortality rate. The present communication is concerned with the excretion of C.G. by diabetic women and the effect of oestrogens on this excretion in normal women and in diabetic women.

Methods.—The method used depends upon the increase in the prostatic weight in immature rats after subcutaneous administration of the urine to the animals. The results of the assay are always expressed in i.u. of C.G. per 24-hour specimen of urine. The technique is described in detail in the previous paper.

Results

The effect of orally administered stilboestrol on the C.G excretion in two normally pregnant women was investigated. Fourteen pregnant diabetics were considered in all, and 11 of these had C.G. estimations made at approximately weekly intervals after diagnosis. Only a few readings were made on the other three patients. Stilboestrol was administered to these diabetics, who after 100 days of gestation consistently showed an excretion of C.G. above the normal level of 10,000 i.u. per 24 hours. Six of the 14 cases were shown to have abnormally high C.G. readings at some stage of their pregnancy, and the findings in these cases are discussed below. In the other eight patients the excretion of C.G. appeared to be normal.

Normal Pregnancy

Case 1.—After two weeks' control period stilboestrol in dosage of 25 mg. a day was started at the 21st week of pregnancy (Fig. 2). The dose was increased to 30 mg. a day at the 23rd week. A sharp fall in the C.G. excretion occurred, the reading climbing back to just below its original level on cessation of the treatment.

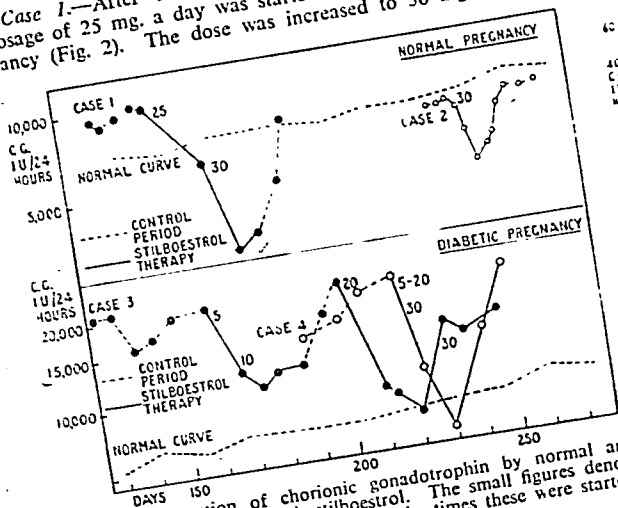

FIG. 2.—Excretion of chorionic gonadotrophin by normal and diabetic women treated with stilboestrol. The small figures denote doses (mg. per day) and are placed at the times these were started. (Cases 1–4).

Case 2.—After one week's control period stilboestrol in dosage of 30 mg. a day was given at the 34th week of pregnancy (Fig. 2). A modest depression of the C.G. level ensued initially, but when the same dose of stilboestrol was continued the excretion of the hormone returned to its original level, this occurring after approximately three weeks' therapy.

Pregnancy in Diabetics

Case 3.—Estimations made from the 17th to 23rd weeks of pregnancy showed an abnormally high excretion of C.G. (Fig. 2). Stilboestrol in relatively small dosage was started at the 23rd week and it produced a significant fall, but the reading rose to slightly above its original level on cessation of the therapy. Subsequent therapy with larger dosage started at the 28th week produced another dramatic fall in the C.G. excretion, but an "escape" phenomenon occurred when the same dosage was maintained. This patient was delivered at the 36th week by caesarean section. The weight of the baby was 6 lb. 7 oz. (2.92 kg.) and of the placenta 1 lb. 10 oz. (0.74 kg.).

Case 4.—An abnormally high C.G. excretion was found when the first estimations were made on this patient at the 27th week of pregnancy (Fig. 2). The dosage of stilboestrol started at the 31st week was rapidly increased by 5 mg. a day to 30 mg. a day and maintained at this level. A rapid initial fall in the C.G. excretion was observed, but this was followed by a rise to approximately the original level after four weeks' treatment. The patient was delivered vaginally at 36 weeks. The birth weight of the foetus was 4 lb. 11 oz. (2.13 kg.) and of the placenta 1 lb. 3 oz. (0.54 kg.).

Case 5.—The very high readings of C.G. obtained in early pregnancy in this patient were originally thought to indicate a delayed peak period, but the excretion remained consistently high well after the 100th day of pregnancy (Fig. 3). Stilboestrol in dosage of 25 mg. a day was started at the 15th week of pregnancy, and this was increased to 30 mg. a day at the 17th week. A fall in the excretion of C.G. occurred, but the titre rose again on cessation of the treatment. Therapy was restarted at the 20th week in dosage of 20 mg. a day, and this was increased to 30 mg. a day at the 25th week. This resulted in a fall in the urinary excretion of C.G. to 10,000 i.u. by the 27th week. After that, however, while the therapy continued the readings climbed steeply. Apparently the patient had become quite refractory to stilboestrol in the dosage given. The oestrogen was stopped at the 30th week of pregnancy and restarted at the 31st week. Some degree of sensitivity appeared to have been re-established as a slight fall in the

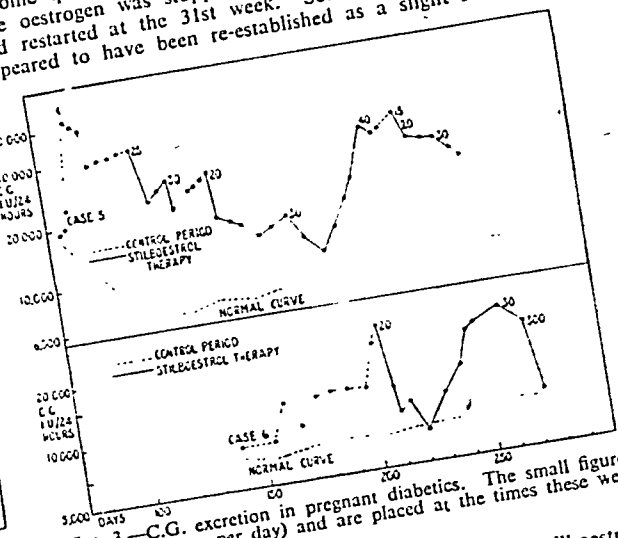

FIG. 3.—C.G. excretion in pregnant diabetics. The small figures denote doses (mg. per day) and are placed at the times these were started. (Cases 5 and 6).

excretion was obtained with a smaller dosage of stilboestrol. This patient was delivered by caesarean section at the 37th week. The weight of the baby was 6 lb. 1¼ oz. (2.76 kg.) and of the placenta 1 lb. 2 oz. (0.51 kg.).

Case 6.—The rise in C.G. excretion in this patient occurred at the 24th week of pregnancy (Fig. 3), readings before that time being comparatively normal. Stilboestrol in dosage of 20 mg. a day was started at the 29th week. A transitory depression of the reading was obtained, but again the "escape" phenomenon was observed. A dose of 300 mg. given to induce labour approximately halved the C.G. reading. This patient was delivered by caesarean section at 41 weeks. The foetus weighed 9 lb. 4 oz. (4.2 kg.) and the placenta 1 lb. 15 oz. (0.88 kg.).

Case 7.—The excretion of C.G. was relatively normal in this patient until the 28th week of pregnancy, when a steep rise occurred (Fig. 4). Stilboestrol in dosage of 20 mg. a day was

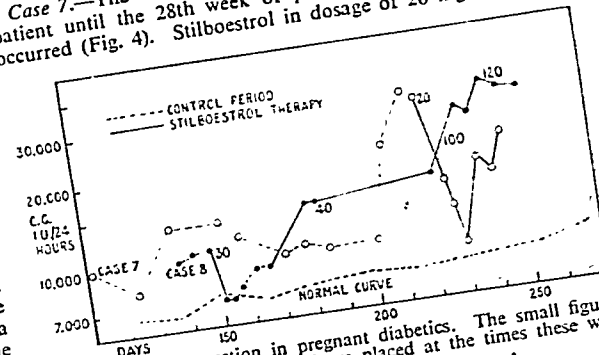

FIG. 4.—C.G. excretion in pregnant diabetics. The small figures denote doses (mg. per day) and are placed at the times these were started. (Cases 7 and 8).

started at the 31st week and produced a dramatic fall in the titre, but the reading climbed rapidly again while the therapy continued. This patient developed a mild degree of pre-eclampsia at 32 weeks. Delivery was by caesarean section at 34 weeks. The baby weighed 6 lb. 3 oz. (2.81 kg.) and the placenta 1 lb. 5 oz. (0.6 kg.).

Case 8.—Stilboestrol was administered to this patient at the 21st week of pregnancy for experimental purposes although the C.G. excretion was not unduly high (Fig. 4). A characteristic depression of the titre occurred, but the excretion rose when the treatment was stopped. No further readings were made until considerably later in pregnancy, when, although the patient was receiving massive doses of oestrogens (up to 120 mg. a day of stilboestrol supplemented by 100 mg. a day of oestradiol

benzoate at the 34th week), the C.G. level remained very high, again indicating refractoriness to the oestrogen. Delivery was by caesarean section at the 36th week of pregnancy. The foetus weighed 9 lb. 15¾ oz. (4.53 kg.) at birth and the placenta 2 lb. (0.9 kg.).

In Fig. 5 the results are shown in those pregnant diabetics in whom the excretion of C.G. was within normal limits.

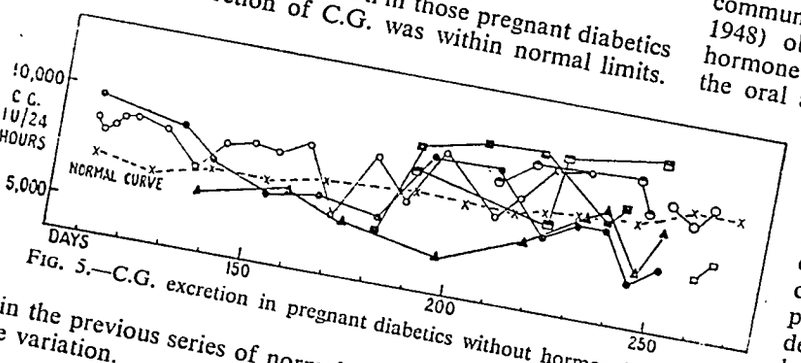

FIG. 5.—C.G. excretion in pregnant diabetics without hormonal therapy.

As in the previous series of normal cases, there is relatively little variation.

Discussion

From the evidence cited above it is apparent that a proportion of pregnant diabetic women (6 out of 14 studied) showed an abnormally high excretion of C.G. as compared with normally pregnant women. In the remaining eight diabetics the readings were perfectly normal (Fig. 5). Hormonal therapy was given only to those patients who after 100 days of gestation consistently showed a C.G. excretion of over 10,000 i.u. in 24 hours.

Stilboestrol when administered orally to normal and diabetic women, even in relatively small dosage, invariably produced a fall in the C.G. excretion. The degree of depression varied from case to case but tended to be more pronounced in early than in late pregnancy. On a constant dosage of the oestrogen, however, this depression was not maintained, the readings tending to climb back to their original level while the patient was still receiving treatment. This may be described as an "escape" phenomenon. At this stage an increase in dosage of stilboestrol temporarily produced another depression of the reading. Certain patients, however, seemed to become completely refractory to stilboestrol even in massive dosage. This is well illustrated by Case 8, which in the later stages of pregnancy was receiving 120 mg. of stilboestrol a day supplemented by oestradiol benzoate without depression of the C.G. level. There is some evidence (see Cases 3 and 5) that by cessation of the treatment for a few days sensitivity to the drug may be re-established and a depression of the C.G. level produced by a dose smaller than that previously employed.

The effect of stilboestrol on the C.G. excretion can therefore be considered to have five phases: (1) initial depression, (2) subsequent escape, (3) further depression by increase in dosage, (4) refractoriness after prolonged treatment, and (5) increased sensitivity to oestrogen on restarting treatment after stopping it for a few days.

The mechanism of action of oestrogens in producing these effects is not clear. Smith and Smith (1948), who first observed the rise in C.G., considered it a "compensatory" one due to lack of oestrogen and progesterone, and showed that oestrogen therapy will correct this.

Studies in the experimental animal have shown that oestrogen may suppress or inhibit the gonadotrophic activity of the anterior pituitary (Meyer and Biddulph, 1941; Meyer, Biddulph, and Finnerty, 1946). In the human, Jones and MacGregor (1936) observed that the injection of oestrogen into women at the menopause resulted in a cessation of the increased gonadotrophic hormone excretion in the urine, and Albright (personal communication to Professor J. H. Gaddum, September, 1948) obtained a depression of the follicle-stimulating hormone titres in the urine of menopausal women by the oral administration of stilboestrol. The rationale of oestrogen therapy in Cushing's syndrome (Dunn, 1938; Rakoff, Cantarow, and Paschkis, 1941) and in acromegaly (Schrire and Sharpey-Schafer, 1938; Goldberg and Lisser, 1942) is in virtue of the inhibitory effect produced on the anterior lobe of the pituitary. There does not appear, however, to be any previously published work on the effect of oestrogens in depressing the excretion of the gonadotrophic hormone elaborated by the placenta during pregnancy.

In the pregnant diabetics studied so far, no definite correlation has been found between the C.G. excretion on the one hand and the weight of the baby and placenta on the other. There also appeared to be no relation between the C.G. excretion and the insulin requirements during pregnancy in these patients.

Summary

Estimates have been made of chorionic gonadotrophin (C.G.) in the urine of 14 pregnant diabetics. The prostatic weight in immature rats was the end-point of the assay.

In 6 of these 14 cases the figures for C.G. excretion obtained were abnormally high when compared with that of normal women.

The administration of oestrogens caused an evanescent fall in the amount of C.G. excreted in the urine per 24 hours.

I am deeply indebted to Professor J. H. Gaddum for his help and guidance. I should like to thank Professor R. J. Kellar and Professor D. M. Dunlop for permission to study the cases under their charge. Thanks are also due to Dr. C. F. Rolland and Dr. G. D. Matthew for advice on the medical and obstetrical aspects of this paper. Finally, I am much indebted to Miss M. Mackay for the excellent technical assistance she has given me in carrying out the experiments.

VITAMIN A, TOTAL CAROTENOIDS, AND THYMOL TURBIDITY LEVELS IN PLASMA

TEST IN NORMAL SUBJECTS RESIDING IN THE MIDLANDS DURING 1947

BY

DOROTHY ADAMS CAMPBELL, M.A., M.B., B.S.

AND

EVA L. TONKS, M.Sc.

(*From the Research Department, Birmingham and Midland Eye Hospital, Birmingham*)

In the course of a previous investigation into the cause of nystagmus in coal-miners we estimated the levels of vitamin A and total carotenoids in the plasma (Campbell and Tonks, 1948). Thymol turbidity tests were performed at the same time on a number of cases in order to exclude the possibility of liver dysfunction as a cause of fluctuation in these constituents. Since the diet of the majority of people had been rather drastically altered by war and post-war conditions in Great Britain, we were obliged to establish "normal" figures for comparison. It was thought that the values obtained might be of practical interest to other investigators engaged on similar problems.

Methods

Estimation of Vitamin A and Total Carotenoids in Plasma

Clausen's application of the Carr–Price colorimeter method was the means used in this procedure. The colour was measured in a Hilger absorptiometer, using filters specially designed for these estimations. The results were read off from standard curves prepared as suggested by Yudkin (1941).

The following reagents were used: (1) ethyl alcohol (redistilled); (2) petroleum ether (boiling point 40–60° C.); (3) chloroform—alcohol-free and dried over anhydrous sodium sulphate; (4) antimony trichloride solution 30% (w/v) in dry chloroform; this is a saturated solution freshly prepared and filtered, and is cleared of any turbidity by the addition of one drop of acetic anhydride.

Preparation of Standard Curves.—Carotenoids:—For this purpose pure β-carotene was obtained from the National Institute for Medical Research. A weighed amount (about 0.25 mg.) was dissolved in 100 ml. of petroleum ether (boiling point 40–60° C.). Aliquots of this solution were made up to 5 ml. with petroleum ether, and readings were taken in the absorptiometer to determine the standard curve for β-carotene, using the special filter combination provided by Hilger for carotenoids. *Vitamin A*:—Capsules of vitamin A alcohol of high purity were very kindly given to us by Roche Products, Ltd., to whom we offer our thanks. The contents of one capsule were weighed and made up to a known volume with chloroform. Under our conditions 1 ml. of this solution contained 27.25 i.u. Each aliquot taken was made up to 0.5 ml. with chloroform, and then 5 ml. of antimony trichloride solution was added. The resulting colour was read off on the absorptiometer within 10 seconds of the addition of the reagent, using the special combination of filters designed by Hilger for the estimation of vitamin A.

Correction Curve for the Blue Colour Produced by β-carotene and Antimony Trichloride.—A solution of a weighed quantity of β-carotene (1.2 mg.) was made up to 100 ml. with chloroform. Aliquots were made up to 0.5 ml., and 5 ml. of antimony trichloride solution was added. The special filter for vitamin A was used in the absorptiometer, and readings were taken within 10 seconds of mixing the reagents.

From these readings graphs were constructed so that results could be ascertained with accuracy and speed.

Two millilitres of plasma was placed in a stoppered centrifuge tube, 2 ml. of ethyl alcohol was added slowly, and the contents thoroughly mixed. To this mixture was added 4 ml. of petroleum ether. The stopper was inserted and the tube shaken at frequent intervals for half an hour. The mixture was then allowed to settle into its two layers or was centrifuged. An aliquot of the top layer (usually 3.6 ml.) was then transferred to an absorption cell, made up to 5 ml. with petroleum ether, and a reading taken using the carotenoid filter. The equivalent value in terms of β-carotene was then obtained from the standard curves and calculated for 100 ml. of plasma.

The petroleum ether solution in the cell was evaporated to dryness by placing the cell in a bath of warm water (40–60° C.). A gentle current of dry air or nitrogen was used to assist evaporation. The residue was dissolved in 0.5 ml. of dry chloroform. With the use of the special vitamin-A filter the cell was placed in the rack of the absorptiometer and 5 ml. of antimony trichloride solution added. The reading was taken within 10 seconds of the addition of the reagent.

The amount of vitamin A present in the cell was calculated by reading the value from the standard curve for vitamin A and subtracting the amount of blue colour due to the reaction of the antimony trichloride with the estimated amount of carotenoids present. From this value the amount in 100 ml. of plasma was calculated.

Thymol Turbidity Test

This test was originally described by Maclagan (1944), but in order to get more precise comparable values the modification of Ley, Lewis, and Davidson (1946) was used, in which a barium sulphate suspension was employed as a standard and the turbidity was measured in the Hilger absorptiometer. The results given in this paper, therefore, are expressed as being equivalent to the corresponding amount in millilitres of barium sulphate suspension.

A slight modification was introduced—namely, the performance of a blank test with 0.1 ml. of plasma and 6 ml. of 0.9% sodium chloride. The reading of this blank test on the standard barium sulphate suspension curve was subtracted from the value obtained in the usual way in the case of lipaemic or slightly haemolysed plasma.

Results

Vitamin A and Total Carotenoids

Our series consisted of 133 normal adults (116 men and 17 women) varying in age from 18 to 73 years. They included housewives, office workers, factory hands of all types, and labourers, and came from all walks of life. They were tested only when free from infection, as Brenner and Roberts (1943) found that feverish colds reduced the blood level of vitamin A by one-half. All specimens of blood were collected at approximately three hours after

a meal, but no attempt was made to obtain fasting specimens, since Kimble (1939) found that ordinary meals do not cause a measurable increase in either vitamin A or carotene within two to six hours.

The figures in our 133 subjects were:

Total carotenoids (μg./100 ml.)	20–199	Mean	80
Vitamin A (i.u./100 ml.)	69–158	,,	108

These figures are strikingly different from those of Haig and Patek (1942) in America, based on 74 measurements on 44 normal people between the ages of 20 and 45:

Total carotenoids (μg./100 ml.)	69–240	Mean	144
Vitamin A (i.u./100 ml.)	109–309	,,	198

It is to be noted that all these subjects were on highly nutritious diets which were estimated to provide at least 13,000 i.u. of vitamin A daily.

Yudkin (1941) in England, in a series of 23 normal adults varying from 18 to 30 years of age, found:

Total carotenoids (μg./100 ml.)	50–240	Mean	120
Vitamin A (i.u./100 ml.)	72–157	,,	113

while Moore and Leitner, during the course of an investigation of the vitamin A requirement of human adults, published in the Medical Research Council Special Report No. 264 (1949), collected a series of 195 cases, comprising 112 subjects with illnesses not expected to affect the vitamin A value, and 83 normal subjects. They give the following figures as their mean values:

	All Cases	Normals
Total carotenoids (μg./100 ml.)	92	100
Vitamin A (i.u./100 ml.)	121	128

Their series was collected from residents in the London area in 1946, while ours, collected during 1947 in the Midlands, are lower than these, both in carotenoids and in vitamin A levels.

The long-continued low intake of fat due to rationing restrictions accounts for the fact that our standards for the average blood level of carotenoids and vitamin A in this country are lower than those considered normal by American standards. This must be borne in mind when assessing the nutritional state of persons suffering from disease.

Variation with Age.—Taking our cases in approximately 10-year age groups, the total carotenoids and vitamin A figures show a slight variation with age (Table I).

Influence of Season.—There was a slight fluctuation in the vitamin A values when grouped in two-monthly periods throughout the year, while the carotenoids showed a steady rise from March/April to November/December (Table III)

TABLE III.—*Seasonal Variation in Total Carotenoid and Vitamin A Content of Blood Plasma*

	Jan. Feb.	Mar. Apr.	May June	July Aug.	Sept. Oct.	Nov. Dec.
Total carotenoids (μg./100 ml.)	82	65	69	75	82	97
Vitamin A (i.u./100 ml.)	110	94	108	113	108	112

Influence of Occupation.—The cases investigated have been grouped into four categories to see if any difference in carotenoid and vitamin A blood levels resulted from hard physical exercise and consequent increased metabolism (Table IV). The "heavy" category of occupation in this series included all those people who do hard manual labour, with the exception of coal-miners. An additional group of 133 miners (divided into "surface" and "underground" workers) shows figures comparable with those for other heavy industries, the levels being particularly low in miners working underground (Table V).

TABLE IV.—*Influence of Occupation on Total Carotenoid and Vitamin A Content of Blood Plasma*

	Occupation			
	Heavy	Medium	Light	Sedentary
Total carotenoids (μg./100 ml.)	76 (37 cases)	79 (34 cases)	88 (32 cases)	81 (30 cases)
Vitamin A (i.u./100 ml.)	102	109	111	113

TABLE V.—*Variation of Total Carotenoid and Vitamin A Content of Blood Plasma in Coal-miners*

	Miners, Surface	Miners, Underground
Total carotenoids (μg./100 ml.)	72 (53 cases)	67 (80 cases)
Vitamin A (i.u./100 ml.)	102	97

Thymol Turbidity Tests

Thymol turbidity tests were performed on 110 normal adults, giving values varying from 0.2 to 1.85 ml. of barium sulphate suspension with a mean value of 0.59. Ley, Lewis, and Davidson (1946), in a series of 105 healthy young men, found a range of 0.16 to 2.19 ml. with a mean value of 0.63. In our series 84% of the cases had a value of less than 0.9 ml. and 93% a value of less than 1.06 ml. of barium sulphate suspension, while less than 3% had values exceeding 1.5 ml.

It is suggested that the introduction of the blank reaction into this estimation has the effect of reducing the upper limit of the normal range, and that the true range should be 0 to 1.5 ml. of barium sulphate suspension.

TABLE I.—*Age Variation in Total Carotenoid and Vitamin A Content of Blood Plasma*

	18–29 Years		30–39 Years		40–49 Years		50–59 Years		60–73 Years	
	Range	Mean	Range	Mean	Range	Mean	Range	Mean	Range	Mean
Total carotenoids (μg./100 ml.)	20–118	70 (26)	42–199	80 (32)	26–137	80 (26)	40–192	90 (24)	23–190	83 (25)
Vitamin A (i.u./100 ml.)	69–148	106 (26)	84–141	112 (32)	82–158	110 (26)	75–145	109 (24)	80–138	105 (25)

Figures in parentheses indicate the number of cases.

Influence of Sex.—Our series is predominantly male, but the results show the same trend as that found by Kimble (1939) and by Moore and Leitner, in that the carotenoids are higher in females than in males, while the vitamin A is slightly lower in females than in males (Table II).

TABLE II.—*Total Carotenoid and Vitamin A Content of Blood Plasma in Males and Females*

		Total Carotenoids (μg./100 ml.)			Vitamin A (i.u./100 ml.)		
		Range	Mean	No. of Cases	Range	Mean	No. of Cases
Our series	Males	20–199	79	116	69–158	109	116
	Females	52–155	90	17	75–155	105	17
Kimble, 1939	Males	50–300	166	30	87–193	127	30
	Females	90–340	187	34	65–165	91	34
M.R.C., 1949	Males		96	46		146	46
	Females		105	37		110	37

Conclusions

Our cases were collected from patients attending eye clinics for minor accidents, for refraction, or for correction of squint. They may be regarded as a cross-section of the

population of the Midlands, having no obvious disease or chance infection. This being so, our results show that the average blood levels of the total carotenoids and vitamin A are lower in this part of England than those found in other countries.

In the Medical Research Council's Special Report on Vitamin A Requirements of Human Adults are assembled all the available data on the normal value for the carotenoid and vitamin A content of human blood plasma in 195 subjects, and Moore and Leitner, who carried out the investigation, point out that some American authors, in calculating the values for vitamin A, do not appear to have made any correction for the blue colour contributed by carotenoids to the antimony trichloride reaction. They also state that some of the earlier workers in America used the U.S.P. unit, which is now held by Hume (1943) to have only 87% of the value of the international unit, and that it is not always possible in retrospect to be certain which unit was really meant.

These facts may account for the apparent discrepancies between American and English results, as well as the fact that the people of Britain do not have access to unlimited fat, and have not acquired the taste for large quantities of green vegetables and salads. In our series 85% of cases have total carotenoid plasma levels lying between 40 and 120 μg./100 ml., and vitamin A plasma levels between 80 and 130 i.u./100 ml., and these are suggested as being reasonable limits for normality under conditions prevailing in the Midland area of England during 1947.

The results of our investigation indicate slightly lower levels for vitamin A, and considerably lower levels in total carotenoids, compared with those found by other English workers (Yudkin, 1941 ; M.R.C., 1949).

Summary

The levels of total carotenoids and vitamin A in the plasma of 133 normal adults were estimated. The investigation took place throughout the year 1947. The normal range was found to be:

Total carotenoids (μg./100 ml.)	20–199	Mean	80
Vitamin A (i.u./100 ml.)	69–158	"	108

but since 85% of our cases gave values of

Total carotenoids (μg./100 ml.)	40–120
Vitamin A (i.u./100 ml.)	80–130

these are suggested as limits of normality under conditions prevailing in the Midland area of England in the year 1947.

Vitamin A levels showed a slight fluctuation during the year, while the level of the total carotenoids rose steadily from March to December.

Those subjects performing hard manual labour showed lower levels of total carotenoids and vitamin A than subjects engaged in light or sedentary occupations.

Thymol turbidity tests were performed on a series of 110 normal adults, and it was found that when allowance is made for a "blank" test the normal range is 0 to 1.5 ml. of barium sulphate suspension, with a mean value of 0.59 ml.

CHLORAMPHENICOL IN TREATMENT OF INFANTILE GASTRO-ENTERITIS

A PRELIMINARY REPORT

BY

K. B. ROGERS, M.D.
Clinical Pathologist

S. J. KOEGLER, M.D.
Registrar

AND

JOHN GERRARD, B.M., M.R.C.P.
Lecturer in Paediatrics at the University of Birmingham

(From the Children's Hospital, Birmingham)

Bray (1945), Giles and Sangster (1948), and Taylor *et al.* (1949) independently noted a close correlation between the same serologically specific type of *Bact. coli* and epidemic infantile gastro-enteritis. This *Bact. coli* is referred to in this communication as *Bact. coli* B.G.T. (Bray–Giles–Taylor).

During the last ten months one of us (K. B. R.) has studied the appearance of this organism in 86 infants under the age of 1 year admitted to the Birmingham Children's Hospital. Routine rectal swabs were taken on admission and in many cases five days later, and again if a case of gastro-enteritis appeared in the ward. The first isolation of the *Bact. coli* B.G.T. from the stool was noted and the subsequent progress of the infant observed.

Epidemiology

In 17 cases it was possible to calculate the interval between the time of the first isolation of this organism from the faeces and the development of a gastro-intestinal disturbance. In all cases except one this period was less than 22 days; the exception was a case which developed diarrhoea at home 24 days after the first positive rectal swab. The shortest interval was four days, in two cases; the average interval was 11 days. It must be emphasized that in 25 of the 86 cases observed the appearance of the *Bact. coli* B.G.T. in the faeces was followed by no untoward symptoms; these cases were followed for a period of at least one month.

This organism was isolated from the stools of 86 babies under the age of 1 year, 82 of whom acquired the organism after admission to hospital; 25 patients, 10 of whom were less than 4 months old, had no intestinal symptoms, while the remaining 61 developed gastro-intestinal disturbances which varied from a severe gastro-enteritis to a mild diarrhoea with or without vomiting; of these 61 patients 13 died. All of the deaths occurred in infants under the age of 4 months, except in two who were aged 10 months. One of the two, a mongoloid idiot, collapsed and died directly after discharge from hospital, but to what extent the *Bact. coli* was responsible is not known. The other, a case of pink disease, died primarily of respiratory failure associated with an extensive polyneuritis and diaphragmatic palsy, but she also had a severe terminal enteritis. The finding that *Bact. coli* B.G.T. is more commonly associated with severe gastro-enteritis in the younger babies is in agreement with the observations of Taylor *et al.* (1949). That the appearance of *Bact. coli* B.G.T. in the stools is sometimes associated with a fulminating gastro-enteritis is suggested by such typical case histories as the following.

Case 1.—A girl aged 3 months was admitted with pseudo-paralysis due to congenital syphilis, for which she received penicillin. A month after admission *Bact. coli* B.G.T. was isolated from the faeces; 15 days later, after her transfer to another hospital for further antisyphilitic treatment, she developed diarrhoea. Four days after the onset she collapsed and died.

Case 2.—A girl aged 2 months was admitted with cystic fibrosis of the pancreas. Her progress was satisfactory at first, but five days after *Bact. coli* B.G.T. was isolated from the stools she developed a watery diarrhoea and 10 days later she died. Necropsy revealed fibrocystic dystrophy of the pancreas complicated by enterocolitis, bronchopneumonia, adhesive pleurisy, and right otitis media; clinically the severe gastro-enteritis was the cause of her sudden death.

Case 3.—A girl aged 1 month was admitted because she had vomited with increasing severity since birth and had become jaundiced. Diarrhoea was present on admission and the stools contained *Bact. coli* B.G.T. In spite of intravenous alimentation the gastro-enteritis persisted and she died 13 days later.

Case 4.—A girl aged 1 month was admitted with generalized convulsions precipitated by an otitis media. From this she made an uneventful recovery. Four days after admission *Bact. coli* B.G.T. was isolated from the stools; 10 days later gastro-enteritis developed and after nine days she died. Necropsy revealed a haemorrhagic enterocolitis with intestinal pneumatosis and an early peritonitis.

Treatment with Penicillin and Sulphonamides

All cases of severe gastro-enteritis were treated as a routine with intravenous alimentation until the diarrhoea and dehydration were controlled, followed by graded oral feeding. Initially, penicillin and sulphonamides were also administered. These agents helped to control parenteral infections, such as otitis media, but they seemed to have little or no direct effect on the gastro-enteritis. In fact, *Bact. coli* B.G.T. appeared in the stools and gastro-enteritis developed in some cases while the infant was actually receiving both penicillin and sulphonamides. Case 5 is an example.

Case 5.—A girl aged 6 months was admitted with scalded buttocks, and developed gastro-enteritis associated with the isolation of *Bact. coli* B.G.T. while on penicillin, sulphonamides, and streptomycin.

In no case did either penicillin or sulphonamides remove *Bact. coli* B.G.T. from the stools once this organism had made its appearance.

Treatment with Streptomycin

Streptomycin proved to be equally disappointing in its failure to cure gastro-enteritis. Although only 12 cases were treated with this drug, four orally and the remainder by intramuscular injection, the results did not appear to justify further investigation. Our small experience supports that of Holzel *et al.* (1949) and not that of James *et al.* (1948). In Holzel's series 50 of the 79 cases were associated with *Bact. coli* B.G.T., but this organism was not mentioned by James *et al.*, whose cases might therefore have had a different aetiological agent.

In three of our cases which received streptomycin *Bact. coli* B.G.T. was actually isolated from the faeces for the first time while streptomycin was being given for other conditions (miliary tuberculosis, a large infected naevus, and infected scalds of buttocks). Two of these cases developed a severe gastro-enteritis necessitating intravenous alimentation; the third had no more than a mild diarrhoea preceded by a loss of weight. Of the remaining nine patients one died, a second deteriorated whilst on streptomycin, and seven recovered, but only one made a quick recovery. *Bact. coli* B.G.T. disappeared from the stools of only one child while it was receiving streptomycin.

Chloramphenicol

When it was decided to investigate the efficacy of one of the newer antibiotics, chloramphenicol ("chloromycetin") was chosen because all strains tested were sensitive to this drug; they were also sensitive to "aureomycin," but chloramphenicol was used because of its relative stability. Chloramphenicol was first described by Ehrlich *et al.* (1947), who mentioned that *Bact. coli* was sensitive to it. It is felt that the results with this

Table Showing Cases Treated with Chloramphenicol

Case	Sex	Age in Months	Reason for Admission	Days After Admission Before Onset of G.E.	Severity	Duration of Treatment with Chloramphenicol in Days	Complications	I.V. Alimentation	Days Taken to Clear *Bact. coli* B.G.T.	Result	Comments
S.B.	F	6	Scalds of buttocks	13	Severe	13	Infected scalds and G.E.	Yes	5	Died	Died 9 days after disappearance of *Bact. coli* B.G.T. from stools but after diarrhoea had ceased

J.C., J.N., and J.P. were carriers who had recovered from their initial G.E., but who still excreted *Bact. coli* B.G.T. G.E. = Gastro-enteritis.

antibiotic are hopeful enough to warrant a preliminary communication, although it is realized that the number treated is small. The age groups in the different series are not strictly comparable; moreover, individual cases vary so much in severity that, with small numbers, comparisons are invidious. These results can best be illustrated by the following case histories. (For further details of cases see table.)

Case 5 (already referred to).—In spite of treatment with sulphonamides, penicillin, and streptomycin her gastro-enteritis continued, but within five days of starting chloramphenicol *Bact. coli* B.G.T. disappeared from the stools and the diarrhoea ceased. Unfortunately she died from complications due to burns nine days after the disappearance of *Bact. coli* B.G.T. from the faeces. A post-mortem examination was not made.

Case 6.—A boy aged 5 weeks was admitted with meningococcal meningitis. Nineteen days after the first appearance of *Bact. coli* B.G.T. in the stools, and while receiving both sulphonamides and penicillin, he developed a severe gastro-enteritis. No improvement followed the administration of streptomycin, but within three days of starting chloramphenicol therapy the diarrhoea ceased; a day later *Bact. coli* B.G.T. disappeared from the stools. Further recovery was uneventful.

Case 7.—A boy aged 8 months was admitted with pink disease. Fifteen days after admission he developed gastro-enteritis associated with the isolation of *Bact. coli* B.G.T. from the faeces. With penicillin and sulphonamide therapy there was little improvement, but on chloramphenicol the organism disappeared within eight days, the diarrhoea ceased, and he started to gain weight satisfactorily.

Case 8.—A girl aged 4½ months was admitted with thrush and a left parotitis. The infection subsided with the application of gentian violet locally and penicillin systemically, but 10 days after the isolation of *Bact. coli* B.G.T. from the stools she developed diarrhoea and lost 12 oz. (340 g.) in weight in three days. The enteritis did not respond to symptomatic treatment, but when chloramphenicol was given the diarrhoea ceased; *Bact. coli* B.G.T. disappeared from the stools in five days.

In eight additional cases the administration of chloramphenicol, in conjunction with intravenous alimentation where necessary, and graded feedings, was followed by rapid amelioration of the diarrhoea, and *Bact. coli* B.G.T. could no longer be recovered from the faeces. In three cases there was a bacteriological relapse, although no case had a recurrence of the diarrhoea.

Carriers.—Three children who had had diarrhoea associated with the presence of *Bact. coli* B.G.T. but had recovered from their diarrhoea still excreted this organism in the faeces. They were given chloramphenicol. In one case *Bact. coli* B.G.T. was not recovered from the faeces after the third day of treatment. In a second the organism was not recovered from the fifth day of treatment until four days after the cessation of treatment, when a bacteriological relapse occurred. In the third case this organism was still present in the faeces after nine days' treatment.

Clearance of the Organism.—The average time for chloramphenicol to effect a clearance of *Bact. coli* B.G.T., except in the carriers already mentioned, was four days, within the limits of two and eight days. In two cases the organism reappeared in the faeces one and seven days after cessation of treatment which had lasted seven to eleven days respectively, but the organisms were still sensitive to chloramphenicol. These cases may have been either true relapses or reinfections, as neither had been discharged from the infected ward.

Parenteral Infection.—Six cases were admitted with an otitis media. No *Bact. coli* B.G.T. were isolated from their faeces, but before these infants were fit for discharge they had not only acquired the organism but had also developed gastro-enteritis. It is understandable that, in the absence of recognition of any organism as a potential pathogen in the stools, the diarrhoea might be ascribed to the inflammation in the ears. In point of fact, the sequence of events would seem to have been an initial infection necessitating admission to hospital, followed by a subsequently acquired intestinal infection. An otitis media was present at the onset of the gastro-enteritis in two cases; in three additional cases an otitis media developed from five to ten days after the onset of the gastro-intestinal infection. In no case was *Bact. coli* B.G.T. isolated from the middle ear.

Other Cases

Case 9 is worthy of special mention as it was the only one in which a primary urinary infection with *Bact. coli* B.G.T. was encountered.

Case 9.—A boy aged 7 weeks was admitted with anaemia, mild jaundice which developed during the week before admission, severe urinary-tract infection, and bilateral otitis media. The urine contained many pus cells, casts, and a few red cells, and gave a heavy pure growth of *Bact. coli* B.G.T. There was no evidence of any abnormality in the blood apart from anaemia. Gastro-enteritis developed three days after admission, but *Bact. coli* B.G.T. were not isolated from the faeces. The urinary infection was not influenced by penicillin, given on account of the otitis media, or by sulphonamides, but responded dramatically, as did the enteritis, to chloramphenicol.

Bact. coli B.G.T. may be associated with diarrhoea in older children; the oldest child known to be affected in this hospital was a girl 4 years old, and although, because of her age, she is not included in this series, her case history is of considerable interest. Soon after she had successfully negotiated a Blalock–Taussig operation she developed severe enteritis in which the only potential pathogenic organism that could be isolated was *Bact. coli* B.G.T. After three days' treatment with chloramphenicol, given for seven days, the diarrhoea ceased and *Bact. coli* B.G.T. was no longer isolated from the stools. Before this case occurred no gastro-intestinal disturbance associated with the presence of *Bact. coli* B.G.T. had been discovered in the general wards of this hospital. The enteritis in this 4-year-old girl began 15 days after a baby who was excreting the organism had been transferred to her ward.

Administration of Chloramphenicol

Chloramphenicol is marketed in 250-mg. enteric-coated capsules, but as infants cannot swallow these the drug has been given as a suspension with tragacanth flavoured with syrup of raspberry and chloroform water. The babies have needed little encouragement to take it in spite of its bitter taste. The dosage given has been 75 mg. per lb. (165 mg. per kg.) body weight per day in six or eight divided doses; the initial dose was twice the maintenance dose.

Complications of Chloramphenicol Therapy

The administration of chloramphenicol has occasionally coloured the stools bright green. Four of the cases developed sore buttocks followed by a spreading generalized dermatitis which cleared only after two weeks, but it is not established that chloramphenicol was responsible. Apart from this possible toxic reaction, no untoward effects have been noted; routine blood counts and urine examinations on all cases have shown no abnormalities.

Further Investigation

A trial with chloramphenicol is now being undertaken on all severe cases of infantile gastro-enteritis, irrespective of the presence of the known specific strains of *Bact. coli*. Although *Bact. coli* B.G.T. is often associated with gastro-enteritis there is no proof of its actual pathogenicity, and, moreover, a number of babies who excrete this specific strain of *Bact. coli* never develop symptoms: there may

have been a previous undetected infection with *Bact. coli* B.G.T. in these cases. On the other hand, an appreciable number of children are admitted with primary gastro-enteritis without any identifiable specific strain of *Bact. coli* in their faeces.

Bacteriology

Routine Examination.—Faeces from cases of gastro-enteritis were examined to exclude the presence of protozoa and cultured on Leifson's desoxycholate citrate medium as well as in selenite enrichment medium to exclude the presence of salmonellae and shigellae. A MacConkey plate was also inoculated and at least four representative colonies were tested by slide agglutination, using Bray and Beavan's (1948) technique, which gave very clear-cut and reliable results. All positive colonies were inoculated into sugars, and a culture was sent to Dr. Joan Taylor, who very kindly confirmed their identity.

Sensitivity of the Organism to Chloramphenicol.—*Bact. coli* B.G.T. was inhibited in concentrations of chloramphenicol varying between 2 to 4 μg./ml. Tests were made using representative colonies from each specimen from which *Bact. coli* B.G.T. was isolated whilst the child was on chloramphenicol treatment or if the organism reappeared after treatment had been stopped. No change in sensitivity of the organism was shown in these experiments. This is in agreement with the work of Smadel *et al.* (1949) and Alexander *et al.* (1949). This result is very different from those obtained with streptomycin, when insensitive variants began to appear in nearly all cases within 24 hours of the initiation of treatment. In most of the antibiotic-treated cases specimens of faeces were obtained once or twice daily during treatment and daily for two weeks after its cessation or until the patient was discharged.

Blood Levels.—Estimations of chloramphenicol blood levels were made; the technical difficulties were not fully overcome, but by the use of a modification of the technique described by Fleming and Smith (1947) levels up to 120 μg./ml. were obtained. The test organism used was a strain of *Bact. coli* B.G.T. from Case 5. There seemed to be definite individual variations in the absorption of the drug by the patient, so a relatively high dose of chloramphenicol was employed.

Summary

In Birmingham, as in many other parts of Great Britain where it is sought, *Bact. coli* B.G.T. has been found to be intimately associated with epidemic infantile gastro-enteritis. The enteritis did not respond to the administration of sulphonamides, penicillin, or streptomycin, but the response, both clinically and bacteriologically, to chloramphenicol has been most encouraging.

We would like to express our thanks to the staff of the Children's Hospital, Birmingham, especially to Professor J. M. Smellie for his encouragement and most valuable criticism, to Sister M. Coker for her co-operation, and to Dr. Joan Taylor for much advice and help; also to Dr. C. Giles, who supplied the first antisera used in this investigation.

PARATYPHOID B FEVER TREATED WITH CHLORAMPHENICOL

BY

MICHAEL CURTIN, M.D., M.R.C.P.I., D.P.H.

Registrar, Sheriff Hill Infectious Diseases Hospital, Gateshead-on-Tyne

The clinical course of paratyphoid fever is subject to much variation. Compared with typhoid fever it is in general a milder disease, although attacks of paratyphoid fever occur which both in severity and in duration rank with typhoid even of the most severe form. Owing to this variation in degree of clinical illness it is difficult to assess the response to any particular form of treatment. Reports on paratyphoid B fever treated with chloramphenicol (chloromycetin) have been few. Christie (1949) has reported briefly on seven cases, and Kiledjian (1949) and Montuschi (1949) have each reported on a single case. As much investigation remains to be done before the full effect of the drug on paratyphoid fever can be finally assessed, and as it will be some time before an optimum scheme of dosage can be arrived at, the following report may be of interest.

Betweeen June and October, 1949, six clinical cases of moderately severe paratyphoid B fever were admitted to Sheriff Hill Infectious Diseases Hospital. The diagnosis was confirmed in all cases by culture of *Salmonella paratyphi B*. All patients had been ill for some days before admission; treatment with chloramphenicol was started in three cases at the end of the first week, in two cases during the second week, and in the sixth case early in the third week of disease. The dosage and the period of administration of the drug varied, patients who were admitted later in the series receiving larger doses over a longer period. The frequency of administration remained constant, the drug being given at four-hourly intervals.

In addition to the above cases, three apparently healthy faecal carriers of *Salm. paratyphi B* were admitted and treated with chloramphenicol.

Case 1

A girl aged 11 was admitted on June 21, 1949, complaining of malaise, headache, anorexia, diarrhoea, and abdominal pain of five days' duration.

On examination she was obviously toxic, cerebration was dull, her mouth was dry, and her tongue was heavily furred. The abdomen was tumid and slightly tender. The spleen was just palpable. Her temperature was 99.4° F. (37.4° C.) and pulse 120.

Progress and Treatment.—On admission penicillin (200,000 units four-hourly) and sulphasuxidine (8 g. daily) were given and continued for five days. There was no improvement: diarrhoea, abdominal pain and tenderness, pyrexia, and drowsiness persisted. *Salm. paratyphi B* phage type 3A was cultured from faeces. On the tenth day of disease a course of chloramphenicol was

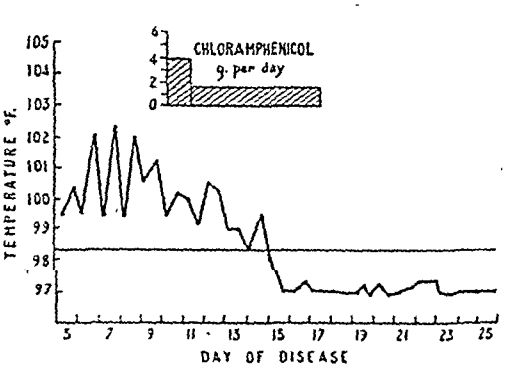

Chart 1.—Case 1.

started (1 g. in first hour, 0.5 g. four-hourly for 24 hours, and then 0.25 g. four-hourly for six days). On the following day the patient's general condition was improved and she was much brighter mentally. Within 48 hours diarrhoea and abdominal tenderness disappeared. Her temperature was normal in four days (Chart 1). There was no clinical relapse, but *Salm. paratyphi B* was excreted in faeces for six weeks after clinical recovery. *In vitro* tests showed that the infecting organisms were sensitive to chloramphenicol even when the temporary carrier state had developed.

Case 2

A woman aged 29 was admitted on July 1, 1949, with a history of the onset of headache, pyrexia, abdominal discomfort, and constipation 14 days previously. At the time of admission her only complaint was that of general weakness and fatigue. On examination her temperature was 100° F. (37.8° C.) and pulse 102. The tongue was furred, and there was evidence of recent wasting. A mitral systolic murmur was heard, but nothing else abnormal was found.

Progress and Treatment.—After admission the patient progressed favourably for three days. *Salm. paratyphi* phage type 3A was isolated from faeces. On the fourth day there was a sudden rise in temperature accompanied by headache, abdominal discomfort, and mild abdominal tenderness. As it was felt that a relapse had taken place, next day she was given chloramphenicol (1 g. in first hour, 0.5 g. four-hourly for 24 hours, and then 0.25 g. four-hourly for five days). Treatment coincided with general improvement. Her temperature did not show a dramatic response, returning to normal on the fourth day of treatment. A convalescent carrier state developed, and this persisted for eight weeks.

Case 3

A boy aged 5 was admitted on July 6, 1949, with a history of lassitude, anorexia, cough, abdominal pain, and diarrhoea.

On examination he was obviously toxic, drowsy, and irrational, and had bouts of noisy delirium. His tongue was heavily furred. The abdomen was distended, and palpation was resented. The spleen was moderately enlarged. A few rose-coloured spots were present on the abdomen. His temperature was 101.8° F. (38.8° C.) and pulse 98.

Progress and Treatment.—On admission on the seventh day of illness a course of chloramphenicol was started (0.25 g. four-hourly for six days). Next day there was a remarkable change in the patient's condition. He was alert and composed, and the abdomen was was less tender. Within 48 hours diarrhoea had ceased. His temperature returned to normal on the third day of treatment (Chart 2), coincident with clinical recovery. *Salm. paratyphi* phage type 3A was cultured from specimens of blood and faeces taken on the day of admission. A convalescent faecal carrier state developed and lasted for nine weeks.

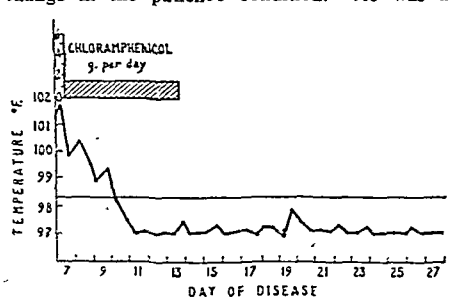

Chart 2.—Case 3.

Case 4

A boy aged 6 was admitted on July 18, 1949, with a history of headache, vomiting, drowsiness alternating with restlessness, and constipation.

On examination his general condition was fair, his tongue was furred, the abdomen was tumid, and a few rose-coloured spots were seen on his abdomen and legs. His temperature was 100.6° F. (38.1° C.) and pulse 112.

Progress and Treatment.—On admission on the seventh day of illness he was put on a course of chloramphenicol (0.5 g. four-hourly for 24 hours and 0.25 g. four-hourly for four days). On the morning following admission several fresh rose-coloured spots were noted. However, his general condition was much improved. The temperature settled to normal in 24 hours. *Salm. paratyphi* phage type 3A was isolated from specimens of blood and faeces taken on the day of admission. The patient continued to excrete the infecting organisms in faeces for seven weeks after termination of treatment.

Case 5

A woman aged 40 was admitted on August 27, 1949, with a history of headache, generalized abdominal pain, constipation, and malaise for six days.

On examination cerebration was dull and speech was sluggish. There was well-marked abdominal tenderness. The tongue was furred. The temperature was 101° F. (38.3° C.) and pulse 92. There were no other abnormal findings.

Progress and Treatment.—On admission the patient was put on a course of penicillin (200,000 units four-hourly) and sulphadimidine (sulphamezathine) (six tablets in the first hour, three four-hourly for 24 hours, and then two four-hourly to a total of 40 g.). Abdominal pain and tenderness, drowsiness, and pyrexia persisted. Faeces were reported as positive for *Salm. paratyphi B* phage type Taunton. Serum gave a positive agglutination with this organism to a titre of 1 in 250 (H). On the 14th day of disease a course of chloramphenicol was begun (2 g. in first hour, 0.5 g. four-hourly for five days, and then 0.25 g. four-hourly for four days—a total of 23 g. in nine days). Within 24 hours there was a change in the patient's condition. She was brighter and said she felt much better. This was in marked contrast to her previous outlook. The abdominal tenderness improved, disappearing after three days. Her temperature was normal on the fourth day (Chart 3). Faeces were still positive for *Salm. paratyphi B* on the fifth day of treatment, but negative thereafter. *In vitro* tests showed that the infecting organism (*Salm. paratyphi B* phage type Taunton) was sensitive to chloramphenicol.

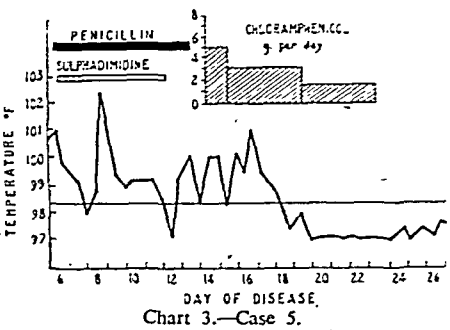

Chart 3.—Case 5.

Case 6

A boy aged 12 was admitted on September 19, 1949, with a history of headache, abdominal pain, pyrexia, and constipation for four days.

On examination the abdomen was moderately distended. The tip of the spleen was palpable. Rose-coloured spots were present on the abdomen and legs; there was slight generalized adenitis; and the tongue was furred. His temperature was 99.8° F. (37.1° C.) and pulse 94.

Progress and Treatment.—Cultures of blood and faeces were positive for *Salm. paratyphi* phage type 3A. Serum gave a positive agglutination with this organism to a titre of 1 in 250 (H). Chloramphenicol was begun on the seventh day of illness (2 g. in first hour, 0.5 g. four-hourly for five days, and then 0.25 g. four-hourly for four days—a total of 23 g. in nine days). There was a dramatic change in the patient's condition. Within 24 hours he no longer complained of headache or abdominal pain. His temperature became normal in 18 hours and, apart from a slight rise (99° F., or 37.2° C.) on the fifth day, remained normal. Faeces were negative for *Salm. paratyphi* on the fifth day. Four subsequent specimens were also negative.

Carriers

During July three apparently healthy faecal carriers of *Salm. paratyphi B* phage type 3A were admitted and treated with chloramphenicol. The dosage given was 16.5 g. in seven days (0.5 g. four-hourly for four days, and then 0.25 g. four-hourly for three days). This dosage had no effect on the carrier state.

Comment

The satisfactory evaluation of the effect of chloramphenicol is not possible in so small a series of cases, especially in the absence of a control group. The rapid improvement and clinical recovery which coincided with treatment, however, were most impressive. This was particularly so in those treated early in the disease.

The dosage of chloramphenicol adequate to produce a well-marked clinical response did not in all cases render the faeces free from the infecting organisms. A similar observation was made in the case of typhoid fever by Woodward *et al.* (1949) and by Rumball and Moore (1949).

In vitro tests showed that both *Salm. paratyphi B* phage type 3A, and *Salm. paratyphi B* phage type Taunton were sensitive to chloramphenicol. It was encouraging to note that in a case in which sensitivity tests were carried out after treatment the organism had not become resistant to chloramphenicol.

It remains to be seen whether larger doses over longer periods will prevent the development of the convalescent carrier state, and whether the drug is effective in treatment of the chronic carrier condition.

I am indebted to Dr. J. Grant, medical superintendent, for his invaluable advice in the preparation of this paper, and to Dr. R. Norton, Director of the M.R.C. Public Health Laboratory, Blakelaw, Newcastle-upon-Tyne, who carried out all bacteriological investigations, including the chloramphenicol sensitivity tests.

DIFFRACTION METHODS OF MEASURING RED CELL DIAMETERS

THEIR USE IN CLINICAL HAEMATOLOGY*

BY

ALAN J. HIRD, M.B., Ch.B., B.Sc., M.R.C.P.

(From the Gardiner Institute of Medicine, University of Glasgow)

An important feature of many anaemias is the alteration which occurs in the size of the average red cell. This alteration is important in diagnosis and in treatment, since, for example, many anaemias associated with increased red cell size have a common aetiological basis and respond to liver therapy.

The recognition of changes in red cell size can be made in various ways. Probably the oldest is direct inspection of blood films, stained or unstained, under the microscope —a method fraught with difficulty even for those accustomed to making blood examinations and with positive danger for those not so accustomed. Actual measurement of the diameters of a large number of cells (Price-Jones, 1929) converts the method into one of considerable accuracy but of such tediousness that it is ruled out except for special research. An entirely different method, depending upon measurements of the packed cell volume and of the red cell count, gives a value for the mean corpuscular volume (Wintrobe, 1946). While the packed red cell volume can be determined with an accuracy of ±1%, the red cell count (and consequently the mean corpuscular volume) is subject to errors of at least ±5%.

An ingenious alternative method for measuring the mean diameter of red cells depends upon the diffraction of light around the edges of the cells in an unstained film in a manner similar to that which occurs in a diffraction grating By suitable optical methods the diffracted light can be projected upon a ground-glass screen as a series of coloured haloes (when ordinary white light is used). The diameter of the haloes varies inversely with the average diameter of the red cells. This method was originally described by Pijper (1919), and a later article (Pijper, 1947) gives a full historical review, including references to modifications by other workers, together with a detailed account of the technique and its application. It is claimed not only that the mean cell diameter can be determined but also that the degree of anisocytosis can be estimated by the degree of spread between the inner violet and outer red rings Brief descriptions of the method will also be found in the standard textbooks on haematology (Whitby and Britton. 1939 ; Todd and Sanford, 1943 ; Wintrobe, 1946). Some workers have cast doubt upon the accuracy of claims made for diffraction methods (e.g., Fullerton *et al.*, 1933), and the general impression derived from a study of the literature is that the method is a useful confirmatory one but not reliable enough to be of use as a single critical method of diagnosis. A modification of the method, using two lamps (Pryce, 1929), has simplicity to commend it, but has been criticized by Pijper on the ground that it does not measure the diameter of the average cell but that of the smallest cell present in any considerable number.

Objects and Methods of Present Investigation

The object of this investigation was to determine whether the simple diffraction method of measuring the mean red cell diameter was of value in addition to or in place of more elaborate studies. Several uses were considered: (1) as a "screening" device in the diagnosis of untreated cases of anaemia ; (2) as a control in the treatment of cases of pernicious anaemia ; and (3) in the investigation of certain other conditions, particularly liver disease.

The study covers a period of almost two years, during which time all new cases showing features of haematological interest in one medical unit were personally investigated, and many followed up at intervals. In addition to conditions usually grouped under the heading of primary blood diseases a considerable number of disorders primarily involving other systems were also dealt with. Excluding a large number of investigations in which the diffraction method was used but for various reasons a complete blood examination was not made, there remain 353 blood examinations on 205 individuals in which haemoglobin, red and white cell counts, haematocrit, absolute values, sedimentation rate, and icterus index were determined in addition to the measurement of the mean cell diameter by the diffraction method and examination of stained films. Table I shows the numbers of each type of disease investigated.

Blood in all cases was withdrawn from a vein into a small bottle containing the appropriate amount of oxalate mixture (Wintrobe. 1946). Haemoglobin was determined by the oxyhaemoglobin method (Bell *et al*, 1945), using a

*The proofs of this article were passed by Dr. Hird shortly before his tragic death on December 11, 1949.

"Spekker" photo-electric absorptiometer; red and white cell counts were made with the same pipettes, counting-chamber, and cover-glass throughout the entire period, and packed cell volumes were measured by Wintrobe's method. Mean red cell diameters were measured on a "blood cell tester" of Pijper's (1935) design manufactured by Zeiss, the diameter of the yellow ring being used and the conversion table constructed by Pijper (1947) employed to express the value in μ.

In addition, 100 films were also measured by the two-lamp method, which was chosen on account of the extreme simplicity of the apparatus required. Little difficulty was experienced in obtaining consistent readings in films with pronounced macrocytosis, since in them the haloes were small and correspondingly bright: in some films with microcytosis, on the other hand, the colours, being spread out over a wider area, were lessened in intensity, and it was much more difficult to make measurements that could be duplicated. The Pijper apparatus can be read in an ordinarily illuminated room provided that the ground-glass screen is shielded from direct light, but the two-lamp method requires a practically darkened room and a considerable space in which to carry it out. The use of oxalated blood, the delay (never more than one hour) between the withdrawal of blood and the making of films, and the thickness of the film (provided that haloes could be elicited at all) appeared to have little effect on the reading by either method.

Results

Comparison of Pijper's Instrument with the Two-lamp Method of Merlin Pryce.—One hundred consecutive films were read by the two methods, both yellow and red rings being measured in Pijper's instrument, since the two-lamp method depends upon the position of the latter ring. The average mean cell diameter by the two-lamp method was almost exactly 1 μ less than by Pijper's method using the yellow ring (6.91 compared with 7.89) and 0.5 μ less when the red ring was used. There was moderately good correlation between individual readings.

Relation of Mean Cell Diameter to Mean Corpuscular Volume.—The mean cell diameters for the 353 observations were plotted against the mean corpuscular volumes obtained from the red cell count and the haematocrit (Fig. 1). As will be seen, there is a general correlation between the two values, but the degree of scatter is disappointingly wide—e.g., a mean cell diameter of 7.5 μ by the diffraction method was obtained with bloods in which the mean corpuscular volume varied between 58 and 98 c.μ (with an isolated figure of 116). Part of this error is likely to be due to the error in determining the red count, but the discrepancies are greater than can be explained solely on this basis. As a method of estimating macrocytosis (in the sense of increased corpuscular volume), therefore, the mean cell diameter as determined by diffraction methods must be considered unreliable except in the extreme upper range (>8.5 μ), being subject to errors of both commission and omission, while in assessing microcytosis it seems to be valueless, although, unfortunately, no cases showing microspherocytes were encountered in this series.

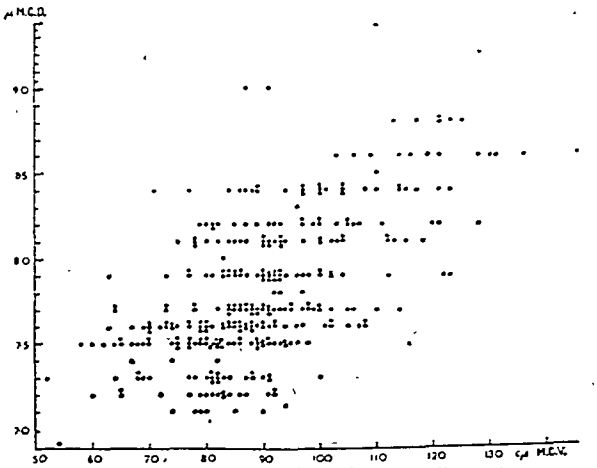

FIG. 1.—Mean cell diameters as determined by Pijper's instrument plotted against mean corpuscular volumes (353 observations).

Use as a Screening Examination in the Investigation of Untreated Cases of Anaemia.—Here the principal, if not the sole, interest centres upon cases showing a high mean cell diameter. Taking the figure of 8 μ as a dividing-line, there were 108 examinations in which a higher value was obtained. Fifty-five occurred in patients with pernicious anaemia or steatorrhoea (including some under treatment), 23 in liver disease, and 30 in miscellaneous conditions. No normal subject was found to have a mean cell diameter greater than 8 μ. There were 11 individuals in whom the value was higher than 8.5 μ, and 9 of these were patients with pernicious anaemia or steatorrhoea, untreated or in relapse. It is of interest that 18 cases of pernicious anaemia or steatorrhoea seen before treatment or in a state of relapse all showed a mean cell diameter of more than 8 μ. In some of these the anaemia was not severe (in one case which presented with subacute combined degeneration of the cord the haemoglobin was 13.9 g. %). It seems improbable, therefore, that an untreated case of pernicious anaemia will be missed by diffraction methods of estimating the mean cell diameter, but the exact diagnosis and the distinction from other causes of a high cell diameter depend of course upon fuller blood examination. Fig. 2 shows the distribution of conditions showing a mean cell diameter greater than 8 μ at the initial examination (excluding patients with pernicious anaemia first seen while under treatment).

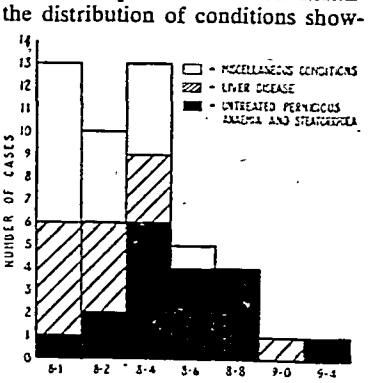

FIG. 2.—Distribution of cases (other than pernicious anaemia under treatment), showing a mean cell diameter greater than 8 μ. The variations in the scale for the mean cell diameter are due to the effect of the conversion table, which does not include certain intermediate values.

Use in Control of Treatment in Pernicious Anaemia.—Fig. 3 (average of 8 cases) shows the return to normal of mean corpuscular volume and mean cell diameter under specific therapy. The fall in mean cell diameter roughly

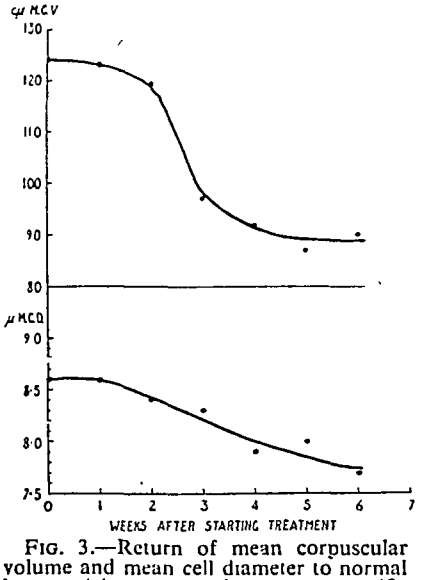

FIG. 3.—Return of mean corpuscular volume and mean cell diameter to normal in pernicious anaemia under specific therapy (average for eight cases).

parallels the decrease in macrocytosis but takes somewhat longer to return to normal levels. Of 25 cases of pernicious anaemia or steatorrhoea followed up as out-patients and about which sufficient data have accumulated, 17 have consistently displayed a mean cell diameter of less than 8 μ, and of these only one has been regarded as not being satisfactorily controlled by treatment. This patient, suffering from steatorrhoea, has shown a haemoglobin of around 10–12 g. % over long periods with, usually, a hypochromic picture, which has responded poorly to oral iron and not at all to increased dosage of liver or to administration of folic acid. Five patients have shown a mean cell diameter of more than 8 μ on one or two occasions, while symptomless and with otherwise normal blood findings. Three have shown a mean cell diameter fairly consistently above 8 μ. One was a woman of 68 years with a severe uterine prolapse for which no radical treatment was possible and which was associated with recurrent cystitis. Despite heavy dosage of liver preparations, haemoglobin averaged 10–11 g. % and macrocytosis persisted. Two other patients, both male, have enjoyed excellent health, with no neurological complications, and shown normal haemoglobin values, but have had persistent macrocytosis (confirmed by mean corpuscular volume determination) despite increases in dosage of liver. It can probably be said that most properly treated patients with pernicious anaemia will show a mean cell diameter of less than 8 μ; while a value higher than this should suggest the need for further investigation but is not by itself necessarily an indication of inadequate treatment.

Use in Other Conditions Showing a High Mean Cell Diameter.—These included a wide variety of diseases (Table II), but the most notable group was that of diseases involving the liver as shown in Table III. It is of interest that in only two of these 18 cases was the mean corpuscular volume greater than 100 c.μ. One case with cirrhosis and one with Banti's syndrome showed a persistently high cell diameter despite the presence of a severe hypochromic microcytic anaemia resulting from oesophageal bleeding.

The degree of spreading of the haloes was determined by measuring the diameters of the red and violet rings in 14 films from patients with liver disease and 12 from patients with pernicious anaemia in relapse, in all of which the mean diameter was greater than 8 μ. The results shown in Table IV, demonstrate no appreciable difference in the degree of anisocytosis in the two conditions. This finding is not in accord with the results of inspection of the films. The red cells in liver disease showed anisocytosis little greater than normal, certainly nothing like that seen in pernicious anaemia, nor was there greater rouleaux formation than normal in the thin parts of the film which were used in the diffraction method. It seems that diffraction methods by themselves are unable to differentiate between the macrocytosis of pernicious anaemia and that of liver disease, and the claim that separation of the rings in the halo represents anisocytosis seems debatable. It is hoped to make this macrocytosis of liver disease the subject of a further study

Pernicious anaemia	8·56	8·00–9·33 (−0·56 to +0·77)

Conclusions

The measurement of the mean red cell diameter by diffraction methods, as an alternative to the determination of the mean corpuscular volume, cannot be recommended, since the relationship between the two is not close enough.

The finding of a mean cell diameter greater than 8 μ by Pijper's instrument (using the yellow ring) will lead to detection of the great majority of cases of pernicious anaemia, either untreated or in relapse, but a number of other haematological conditions will also be included, of which the most strikingly consistent group is that associated with liver disease.

In the control of treatment of pernicious anaemia the presence of a normal mean cell diameter (<8 μ) suggests that treatment is reasonably adequate, but the satisfactory response to treatment of the majority of patients in this small series makes this difficult to assess. On the other hand, the finding of a mean cell diameter greater than 8 μ, even repeatedly, does not necessarily imply inadequate therapy.

Some doubt is cast upon the ability of the method to estimate the degree of anisocytosis.

Summary

The use of diffraction methods of measuring mean red cell diameters is described and their value in routine blood examination discussed. They are of value as a "screening" examination, particularly in detecting untreated cases of pernicious anaemia, but fuller blood examination is required for an exact diagnosis. In following up cases of pernicious anaemia under treatment these methods are of value, in conjunction with other blood findings, but moderately abnormal findings do not always imply an unsatisfactory clinical or haematological state. Liver disease

is often associated with a high mean cell diameter as shown by these methods, a result which may not be arrived at by other means.

My thanks are due to Professor J. W. McNee for advice and criticism in the preparation of this paper.

TWO SUCCESSFUL RESECTIONS FOR CARCINOMA OF PANCREAS

BY

HAROLD DODD, Ch.M., F.R.C.S.

Surgeon to King George Hospital, Ilford; the Royal Hospital, Richmond; the Royal London Homoeopathic Hospital; and the Princess Louise Hospital for Children, Kensington

Two cases of carcinoma of the pancreas in which a resection operation was carried out successfully are described below. The first patient recovered from the operation, gaining 5 lb. (2.27 kg.) in weight, but died five months later from recurrences in the abdomen. The second patient was alive and well when seen 12 months after her operation; she had put on weight, and was able to do her work as a housewife. Up to that date there was no sign of recurrence. The procedure included excision of the caecum, ascending colon, and right transverse colon.

So far no record of a colon excision with the pancreas has been traced in the literature. Hunt (1941) exhaustively reviews all cases of carcinoma of the ampulla of Vater up to that date, and includes synoptic tables showing the type of operation and the results achieved. Cattell (1948) goes more fully into technique, and Brunschwig (1942) reviews the different operative treatments but makes no mention of the colon.

Case 1

A man aged 55 was first seen in October, 1947, when he complained of jaundice of four months' duration. He gave a history of general lassitude, breathlessness, dizziness on exertion, and loss of weight for two years; he said that in the last five months he had lost 19 lb. (8.62 kg.). For 30 years he had had intermittent epigastric pain two hours after a meal, and this was relieved by taking more food and by alcohol. He had had the usual infectious diseases of childhood and also occasional attacks of influenza. In 1917, in Italy, he had had an attack of dysentery, and in 1922 appendicitis, which was treated medically. His mother had died of pulmonary tuberculosis, and his father, at 76 years of age, of heart disease.

On examination he was seen to be a thin spare man, deeply jaundiced. The liver was palpable ½ in. (1.25 cm.) below the costal margin, and the gall-bladder was felt to extend from the ninth costal cartilage to the right iliac fossa. On October 30 he was admitted to a medical ward with a tentative diagnosis of carcinoma of the head of the pancreas.

Operation, November 4.—On opening the abdomen under local analgesia supplemented with open ether (Dr. Goldman) the gall-bladder was seen to be distended to the caecum and there was the scar of a healed duodenal ulcer. The liver was normal in size and consistency, as were also the abdominal viscera. The pancreas was of hard consistency throughout; around the entrance of the common bile duct there was a stony-hard portion which, by inserting the blunt end of a straight needle, was proved to be composed of tissue and not a stone in the common bile duct. A diagnosis was made of carcinoma of the head of the pancreas around the entrance of the ducts into the duodenum. It was considered that a resection of it was possible.

Procedure.—The duodenum was mobilized from the posterior abdominal wall and the head of the pancreas exposed from behind, where a firm irregular mass the size of an almond was present around the opening of the ducts. The stomach was divided above the pyloric antrum. The common bile duct was ligated with stout thread and sewn over, and the duodenum was mobilized to 1 in. (2.5 cm.) beyond the duodeno-jejunal flexure. The pancreas was divided at the junction of its distal and middle thirds; its duct was found to be distended to a size rather larger than that of the ureter. The first 6 in. (15 cm.) of the jejunum was easily drawn up through the mesocolon, which was closed snugly round it. The neck of the gall-bladder was anastomosed to the distal end of the jejunum. The end of the pancreatic duct was anastomosed to the side of the jejunum about 2 in. (5 cm.) distal to the first anastomosis, where the two were easily approximated. The end of the stomach was anastomosed to the side of the jejunum, immediately below the pancreas. A soft rubber drain was passed to these anastomoses and the wound was closed.

Examination of sections of the hard mass around the common bile duct confirmed the clinical diagnosis of carcinoma of the head of the pancreas. The tumour was infiltrated by large anaplastic epithelial cells with pronounced hyperchromatosis and mitosis. Differentiation to glandular structure was seen in parts of the growth. Extensive lymphoid-cell infiltration was also present.

On January 16, 1948, the patient weighed 9 st. 3 lb. (58.51 kg.)—an increase of 5 lb. (2.27 kg.). By February 13 he was again jaundiced, and a recurrence was palpable in the scar of the abdominal incision. He died in April of asthenia.

Comment.—In this case the common bile duct was so large that its anastomosis to the jejunum would have been practicable, and I think this would have been a sounder operation. The patient had been jaundiced for four months when he was first seen, and I make a plea that in cases in which painless jaundice has been present for a month the possibility of carcinoma of the pancreas should be considered and a surgical opinion sought. The mortality of laparotomy is probably 1 to 2%; that following observation of carcinoma of the bile ducts or pancreas is 100%. Some 80% of the patients will recover after resection of the pancreas.

Case 2

A married woman aged 43 was first seen in September, 1948, when she complained of a symptomless lump in the right side of the abdomen, which she had first noted two and a half years before but which had enlarged in the last seven weeks. She had some flatulence and nausea, but no pain or vomiting. Recently her appetite had been poor. She weighed 7 st. 6 lb. (47.17 kg.), but her weight had never been more than 8 st. (50.8 kg.).

On examination a tense cystic, smooth globular swelling the size of a child's head was found on the right side of the abdomen (Fig. 1*a*). The tumour was movable from left to right but not up and down; on pressure it flattened into the loin, but reappeared on coughing; it did not move on respiration. The liver, gall-bladder, kidneys, and spleen could not be felt. On rectal examination the pelvis was found to be clear. Provisionally the diagnosis rested between (1) mobile retroperitoneal sarcoma in the area of the pancreas, duodenum, and transverse mesocolon; (2) an atypical carcinoma of the pancreas; and (3) an atypical pelvic tumour rising into the abdomen.

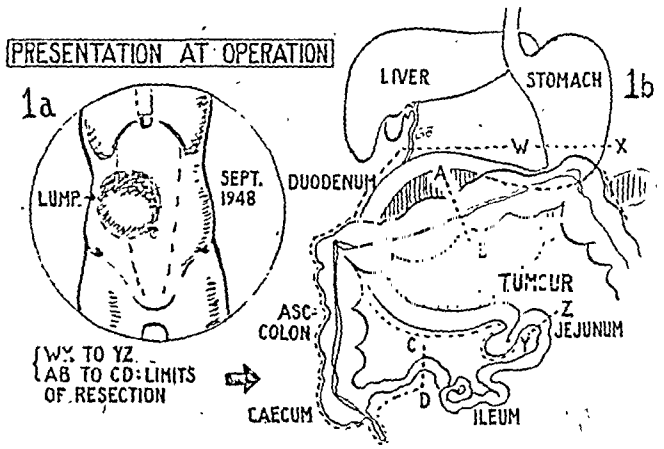

FIG. 1.—Case 2 (*a*) The site of the tumour. (*b*) The tumour as presenting at operation.

Examination of the blood showed: haemoglobin, 42%; red blood cells, 2,600.000 per c.mm.; leucocytes, 10,300 per c.mm. (polymorphonuclears 84%, lymphocytes 16%); blood urea concentration, 34%. A catheter specimen of urine yielded a negative quantitative result, both regarding the deposit and on culture.

Operation.—On October 12 an extended right paramedian incision was made under thiopentone and open ether anaesthesia (Dr. Badock), supplemented by local infiltration of the abdominal wall and splanchnic ganglia with 1 in 1,000 amethocaine hydrochloride. A large vascular, apparently cystic tumour somewhat smaller than an adult head was found lying within the curvature of the duodenum, which was stretched like a strap over it superiorly and laterally. It was adherent to the stomach, duodenum, pancreas, ascending colon, and transverse colon, and bulged through the stretched right mesocolon. The gall-bladder and liver were normal. The swelling was aspirated, but nothing was withdrawn (Fig. 1*b*).

Procedure.—An attempt to shell out the swelling through the mesocolon was abandoned because of copious bleeding and because no plane of cleavage was found. At this stage it was decided that the tumour arose from the pancreas and that its excision was possible and necessary. The colon and duodenum were mobilized from the flank into the wound and the tumour was brought forward with the duodenum stretched tightly over it. The common bile duct and the gastro-duodenal artery were divided between ligatures. The stomach was sectioned above the pyloric antrum. The duodenum was mobilized to the first inch of the jejunum, where it was incised. The mass was brought out of the abdomen attached to the descending and transverse colon and the pancreas; the latter was cut at the junction of the left and middle thirds, well removed from the swelling (Fig. 2). The tumour was so intimately associated with the right colic artery and mesocolon that there was danger, if they were separated, of disseminating the growth and of imperilling the blood supply of the colon; therefore the ileum was sectioned and the transverse colon was transected at its middle. The tumour, with the pyloric antrum, the duodenum and first inch of the jejunum, the last 6 in. (15 cm.) of the ileum, the caecum, ascending colon, hepatic flexure, and right half of the transverse colon, was removed.

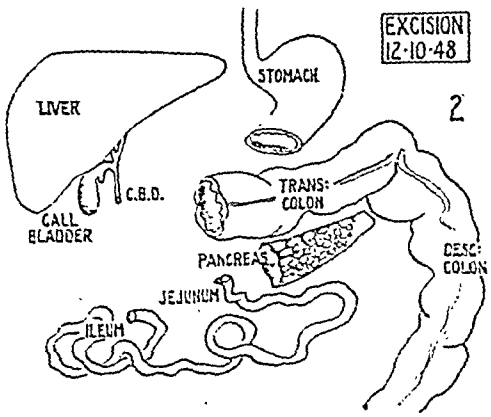

FIG. 2.—Case 2. Showing the parts after excision.

The Reconstruction.—The first 6 in. of the jejunum was drawn through the transverse mesocolon, and the opening in the latter was closed and sutured to it (Fig. 3). The common bile duct was anastomosed to the centre of the end of the jejunum; as it was not dilated, this was difficult. (In dealing with a similar case in future I intend to use the gall-bladder instead.) The pancreatic duct was not dilated, and was considered too small to connect to the jejunal mucous membrane. The end of the pancreas was oversewn and the stump was implanted into the side of the jejunum, the sero-muscular wall being incised to receive it. The stomach was anastomosed end to side to the jejunum. The ileum was united end to end to the transverse colon. This last step constituted a weak link in the chain, but, thanks to the use of penicillin and "sulphatriad" (sulphathiazole, sulphadiazine, and sulphamerazine) combined with plasma and blood transfusion, all was well. The abdomen was closed with nylon sutures, and drainage-tubes were inserted to the anastomoses.

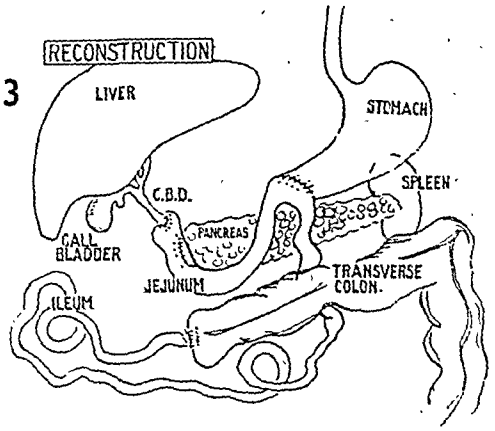

FIG. 3.—Case 2. Showing the reconstruction.

Pathological Report (*Dr. Cuthbert Dukes*).—The specimen consisted of a large oval tumour measuring 5 by 4 in. (12.5 by 10 cm.) and occupying the region of the pancreas. The growth was surrounded by the duodenum, all of which was removed with the operation specimen. The caecum and a portion of the transverse colon were also removed. Microscopical examination showed the tumour to be composed of fusiform epithelial cells arranged in small clumps and distributed irregularly. The histological appearances were those of an anaplastic carcinoma of the body or the tail end of the pancreas. Judged from its histology the growth was probably of a high grade of malignancy.

The patient was given infusions of salt, sugar, and water, and transfusions of plasma and blood, under the direction of Dr. Sterndale Bennett. The post-operative course was uneventful, except for a small discharge of bile for six days, beginning on the fifth day.

The following post-operative results of tests of blood, urine, and faeces were obtained by Dr. John Spencer.

October 18.—Catheter specimen of urine: occasional red blood cells in deposit; culture demonstrated presence of coliform organisms; total chlorides, 6 g. per litre. Blood: haemoglobin, 85%; red cells, 4,350,000 per c.mm.; blood urea, 35 mg. per 100 ml.; plasma proteins, 7.5 g. per 100 ml.

October 19.—Blood: haemoglobin, 90%; red cells, 4,820,000 per c.mm., blood urea, 24 mg. per 100 ml.; resting blood sugar, 160 mg. per 100 ml.

November 5.—Fasting blood sugar, 120 mg. per 100 ml. Thirty minutes after the administration of 50 g. of glucose the blood sugar was 120 mg. per 100 ml., one hour after the glucose was given the reading was 121 mg., and within another 30 minutes the level had fallen to 100 mg. per 100 ml. No sugar was found in the urine. Examination of the faeces gave the following percentage figures: total fat, 7.32; unsplit neutral fat 1.52; split fat 5.8. It was concluded that the fat-splitting mechanism was functioning adequately.

May 30, 1949.—Blood, normal; blood sugar, normal; faeces, fat-splitting mechanism normal; urine, normal. The patient was well in all respects and maintaining her weight and strength.

In December, 1949, the patient was well and was doing her work as a housewife without sign of recurrence.

Comment.—The magnitude of this operation was increased by the resection of the ascending and the transverse colon—a procedure which seems not to have been called for hitherto, as no record of such a step has been found in the literature.

I gladly acknowledge my indebtedness to Drs. Sterndale Bennett, Bentley, and John Spencer (of the King George Hospital, Ilford) for their help with this patient.

Medical Memoranda

Hernia through Foramen of Winslow

The following case was complicated by the fact that the herniated loop had re-entered the general peritoneal cavity through the lesser omentum.

CASE REPORT

A woman aged 41 was admitted to hospital complaining of severe abdominal pain which had come on some 20 hours previously. The onset had been sudden, and the pain had increased in severity, especially in the upper abdomen. Some seven hours after the onset she had vomited, and this had recurred about six times since. The bowels had not moved, nor had she passed flatus since the pain started. She had no other symptoms and the last menstrual period had been two weeks before. On specific interrogation she admitted to a vague type of indigestion which "came on before supper if I had a fatty dinner." The previous history was otherwise entirely negative.

Examination showed her to be a well-nourished woman, and in obvious pain. Her temperature was normal. There was a fine whitish fur on the tongue, and the breath was slightly fetid. The abdomen did not move on respiration, and tenderness and guarding were present all over, but more pronounced in the epigastrium. There was loss of liver dullness in front but not in the axillary line. Rectal examination revealed a rather bulky uterus but no other abnormality. No abnormal signs were found in the other systems except rather frequent extrasystoles. The pulse rate was 92 and the blood pressure 135/85. As she did not vomit after admission the character of the vomitus was not ascertained.

A tentative diagnosis of perforated peptic ulcer was made and a laparotomy performed. In all fairness to those who saw the patient I must record that this diagnosis was made with some trepidation. There were many features which did not fit in—e.g., the ingravescent nature of the pain and the absence of frank rigidity. It was also difficult to reconcile a perforation of 20 hours' duration with her extremely good general condition.

Operation.—Under general anaesthesia a high right paramedian incision was made. On opening the peritoneum the first significant finding was the absence of free fluid; next, the caecum presented in the upper part of the wound, grossly dilated and overlying the liver. This must have been the cause of the loss of liver dullness noted clinically. The findings at laparotomy are shown in Fig. 1. At first this was thought to be a case of volvulus of an abnormally mobile right colon, but on tracing the loop to its base under cover of the liver a fold of peritoneum was found under which the loop had passed. It then seemed that we were dealing with an obstruction by a peritoneal band, and the obvious treatment would be to divide it and thus free the imprisoned gut (Fig. 2).

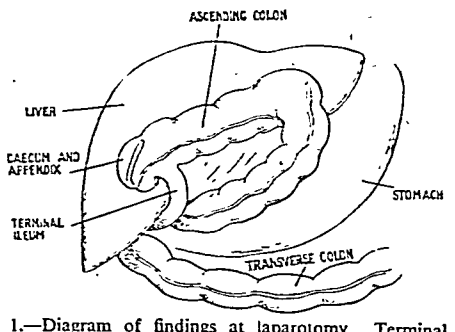

FIG. 1.—Diagram of findings at laparotomy. Terminal ileum, caecum, ascending colon, and part of transverse colon were lying superficially, forming a loop the base of which disappeared under the liver margin.

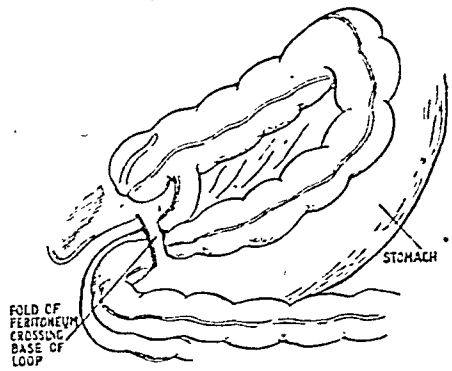

FIG. 2.—Diagram of findings after the liver had been turned up The band of peritoneum shown crossing the base of the loop was the right "free edge" of the lesser omentum.

The true diagnosis was not evident until palpation of the fold revealed forcible pulsation and investigation proved that it contained the hepatic artery, common bile duct, and portal vein, and that it was in fact the right "free edge" of the lesser omentum. The loop of gut had entered the lesser sac through the foramen of Winslow and traversed the gastro-hepatic omentum to reappear in the general peritoneal cavity between the liver and the lesser curve of the stomach.

It was impossible to reduce the hernia by traction, as the loop was so distended and the hiatus so small. Enterotomy was also in vain, and it was decided to resect the offending loop. This was considered feasible in view of the excellent condition of the patient under the anaesthetic; also, the length of mesentery was such as to render the procedure relatively simple. Resection of the loop was accordingly effected and an ileo-transverse colostomy performed. It was then considered that the patient had had as much manipulation as was desirable and no attempt was made to define the precise peritoneal anomalies or to close the gap between the liver and the stomach.

Apart from some infection of the base of the right lung convalescence was uninterrupted and the patient was discharged well three weeks later.

I am grateful to Mr. J. F. Heslop for permission to publish details of the case. Thanks are also due to Dr. S. Kay for the drawings, and to Mr. C. I. Raeburn for his invaluable assistance in the preparation of the report.

JOSEPH N. LEWIS, M.B., B.Ch.,
Late House-surgeon, Park Hospital, Davyhulme.

Treatment of Megaloblastic Anaemia with Vitamin B_{12}

In view of the interest aroused by the recent isolation of vitamin B_{12} simultaneously by Lester Smith (1948, 1949) in Britain and Rickes *et al.* (1948) in the U.S.A., and its action in megaloblastic anaemias (Ungley, 1949), we feel that it would be of interest to record our experience of this substance in the treatment of two cases of pernicious anaemia which were recently under our observation. The amount of substance available to us did not permit treatment to be completed and continued, but a satisfactory and unequivocal initial response was obtained in both cases.

The preparation employed was made by Glaxo Laboratories from the mould *Streptomyces* and was a clear brown liquid, each 1 ml. containing 10 μg. of vitamin B_{12}.

CASE 1

A housewife aged 65 was admitted on September 2, 1949, complaining of increasing lassitude, pallor, and dyspnoea on exertion. Sternal pain radiating down both arms brought on by exercise had also been experienced during the preceding few months. On examination she was found to be rather obese and very pale. There were no detectable abnormalities in the chest, abdomen, or heart, the blood pressure was 150/80, the tongue normal, and oedema was absent; apart from bilateral absence of vibration sense in both legs the central nervous system was normal. An electrocardiogram soon after admission revealed negative T waves in Leads I and II which were ascribed to coronary artery disease. The faecal occult blood was negative.

A blood count the day before admission showed: haemoglobin, 40%; red cells, 1,490,000 per c.mm.; colour index, 1.3; white cells, 5,700 per c.mm. Anisocytosis and poikilocytosis were prominent on examination of the film, and macrocytes were in evidence. The mean corpuscular volume was 143 c.μ, and the concentration method suggested recently by K. S. Rodan showed a few megaloblasts in the peripheral blood.

On September 4, 20 μg. of vitamin B_{12} was injected intramuscularly and no other therapy was permitted. The next day examination of the peripheral blood revealed 2% reticulocytes, and these continued to rise rapidly, reaching a peak of 17% on September 8 (Fig. 1).

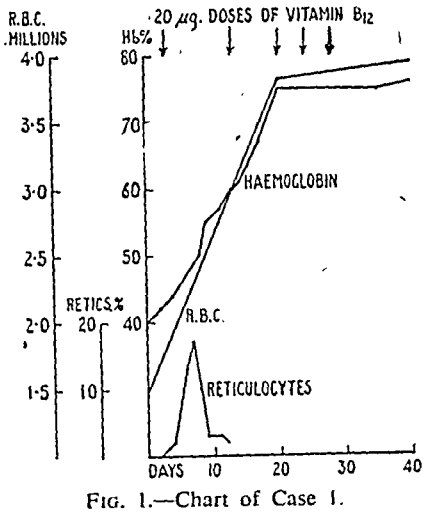

FIG. 1.—Chart of Case 1.

On September 9 the haemoglobin had reached 50%, and by September 14, 60%. Vitamin B_{12}, 20 μg., was administered on September 14, 21, 25, and 29, and on September 21 and 30 the haemoglobin was found to be 75%.

We were impressed by the patient's sense of well-being soon after the first dose, and no ill effects were observed after each injection except that the patient complained of being "drowsy and tired" for a few hours; this effect was thought to be psychogenic. Owing to exhaustion of the supply of vitamin B_{12} an orthodox liver preparation was started on October 8. The total amount of vitamin B_{12} administered was 100 μg.

CASE 2

A woman aged 77 was admitted on August 5, 1949, complaining of increasing weakness, pallor, dyspnoea on exertion, and persistent anorexia. These symptoms had gradually developed over a period of two years, but had become very much worse lately. For a few weeks before admission she had been much troubled by vomiting, and loss of weight had been severe.

On examination the patient was found to be very pale and looked ill. The tongue was smooth and she appeared to have lost a considerable amount of weight. There were no detectable abnormalities in the heart or abdomen, but rales were heard at both lung bases. The blood pressure was 150/90, and the central nervous system showed no evidence of subacute combined degeneration. At that time she was thought to have a carcinoma of the stomach, but a barium meal *x*-ray examination on August 12 showed no stomach-filling defect, although a hiatus hernia was revealed.

A histamine test meal revealed no free acid, and a blood count on August 9 showed: haemoglobin, 40%; red cells, 1,400,000 per c.mm.; white cells, 2,000 per c.mm., colour index 1.4. Marked anisocytosis and poikilocytosis were present in the blood film and macrocytes predominated.

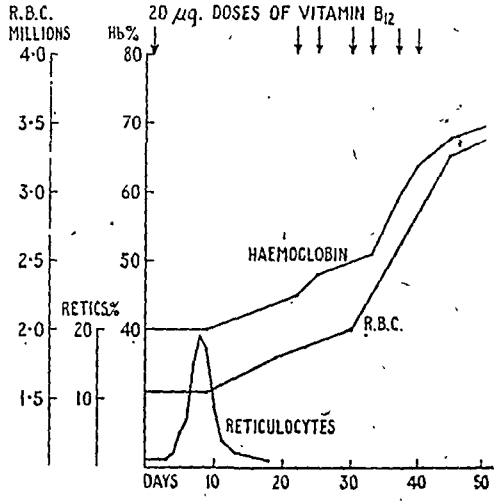

FIG. 2.—Chart of Case 2.

On August 22 a sternal puncture revealed a megaloblastic marrow, thus clinching the diagnosis of Addisonian anaemia. The faeces were negative for occult blood.

Vitamin B_{12}, 20 μg., was administered intramuscularly on August 23 (no other therapy being permitted) and daily reticulocyte counts were made. These were 1% until August 26, when 2% were detected in the peripheral blood. On the 27th the figure had risen to 5% and a peak of 19% was reached on the 30th (Fig. 2).

The haemoglobin was still 40% on August 31, but this now started to rise, although slower than we expected; on September 12 it was found to be only 45%, and in view of what was considered to be an unsatisfactory haemoglobin response a further injection of 20 μg. of vitamin B_{12} was given that day and a similar amount on September 15, 20, 23, 27, and 30—i.e., 20 μg. twice weekly. The total amount of vitamin B_{12} administered in this case was 140 μg.

By September 30 the haemoglobin had risen to 64%, and was 70% on October 11, but in view of the lack of a further supply of vitamin B_{12} an orthodox liver preparation was substituted, the first dose being given on October 11.

In this case, although the rise in haemoglobin was slow, the rapid general improvement was striking. Within two days of the first injection of 20 μg. of vitamin B_{12} vomiting, which had been troublesome, completely ceased, appetite returned, and the patient showed an active interest in her surroundings; this had previously been lacking.

Conclusion.—It seems that vitamin B_{12} prepared from *Streptomyces* is a potent therapeutic agent in megaloblastic anaemia.

We wish to thank Dr. E. Noble Chamberlain for his encouragement and advice, and Messrs. Glaxo Laboratories Ltd. for the supply of vitamin B_{12}.

Reviews

THE PROBLEM OF LABORATORY ANIMALS

Manual for Laboratory Work in Mammalian Physiology. By Fred E. d'Amour and Frank R. Blood. (Pp. 50; illustrated. 15s.) Chicago: University of Chicago Press. London: Cambridge University Press. 1949.

This laboratory manual describes 50 experiments that may be carried out by students on the rat. The authors, who are attached to the University of Denver, have experienced difficulty in providing larger mammals for class work and have therefore devised a course in which the rat is exclusively employed. The experiments are well distributed over the various systems, and if carried out conscientiously will provide the student with an admirable training. Some of the experiments, such as those involving cannulating the carotid artery or jugular vein, require a considerable degree of manual dexterity.

The shortage of cats, rabbits, or dogs is not peculiar to the United States; in this country research in mammalian physiology is grievously handicapped because of the inadequate supplies of suitable animals. Although tens of thousands of cats and dogs are destroyed annually the present state of the law apparently prevents any of these animals being made available even for acute experiments conducted throughout under full anaesthesia, at the end of which time the animal is destroyed. It has been suggested that breeding stations should be established to provide experimental animals. It has been reliably estimated that, apart from the capital costs for land and buildings, the cost of producing a one-year-old cat would be of the order of £10 or £15. It is believed that some of those in authority would rather have this indefensible extravagance allowed than antagonize the antivivisectionists by amending the law to permit the use of stray animals.

Work on the mammal is now everywhere reduced to a few demonstrations for medical students and an inadequate course even for students doing honours degrees in physiology. The shortage of experimental animals is bound to have a crippling effect on the progress of experimental physiology in this country. The use of the anaesthetized rat for class work would involve either re-interpretation or amendment of the Vivisection Act. It might be worth while for the Physiological Society to take up the matter officially with the Home Office. Should the rat ever become available for student work in this country, then d'Amour and Blood's *Manual* will provide an invaluable guide.

SAMSON WRIGHT.

GRADING MUSCULAR FUNCTION

Muscles: Testing and Function. By Henry O. Kendall and Florence P. Kendall. (Pp. 278; illustrated. £2 1s.) London: Baillière, Tindall and Cox. 1949.

There is nothing novel in the detailed testing of muscle function. What is new is the wholesome revival of interest in the subject, which has recently found expression in the appearance of several useful manuals and monographs. This book, the latest and most elaborate of them, is written by two physiotherapists who have given many years to the care of children suffering from poliomyelitis. No one who has visited the Children's Hospital at Baltimore can fail to have been impressed by the superb work being done there by Mr. and Mrs. Kendall, and this book gives a complete picture of the painstaking methods of examination on which this work is based. The action of every important muscle that can be demonstrated by clinical examination is shown in a series of remarkable photographs, and there are pictures of a number of important paralyses, contractures, and errors of posture. The text itself is equally informative.

The practical implications of their teaching must be considered, however. The disturbing feature, and it is an important one, of the Kendalls' work is the complexity of their system of grading muscle power. There can be no question that some method of recording the action of individual muscles (or where necessary muscle groups) is essential in the management of lower motor neurone disorders, of which poliomyelitis and nerve injuries are by far the most important. Even under epidemic conditions clinicians must be prepared to work out muscle charts in every case of poliomyelitis, and a chart is equally necessary for the squirming infant as for the co-operative adolescent. But one must choose a system of examination and assessment that does not make impossible demands on the examiner's time, and in which the differences between the various grades of muscle power are not less than the unavoidable errors of examination. These variations may be due to temporary fluctuation in the patient's condition and to slight differences in technique between one trained observer and another.

In Great Britain the 0 to 5 system of recording is becoming generally accepted, and, having had experience of it in some thousands of cases of nerve injury and poliomyelitis, I would not like to assist at the introduction of anything more elaborate. It is true that one often makes use of pluses, minuses, and half values—e.g., 2+, 3−, or 4½. Yet these "accidentals" must never be taken seriously; they are helpful to the individual observer but are not an argument in favour of a more elaborate system of notation. The Kendalls are no doubt well able to use all twelve of their grades of muscle power, but it would hardly be impertinent to ask what proportion of the residents leaving the Children's Hospital at Baltimore subsequently employ their elaborate system, and, if they do use it, with what degree of accuracy.

Another objection to the Kendalls' system is their employment of percentages to express the various grades. It is reasonable to suppose that a muscle graded as 80% is twice as strong as one graded 40%. Yet this is not so. Grading of such accuracy could be done only with elaborate machinery wholly unsuited to the needs of clinical practice.

Provided he is not repelled or led astray by this system of charting, the anatomist, the physiotherapist, and the clinician will find here a book that should be a constant source of profit. It cost 41s. before devaluation; it will cost more now, but it is still worth it

H. J. SEDDON.

FREUD: A FRESH TRANSLATION

Three Essays on the Theory of Sexuality. By Sigmund Freud. Authorized translation by James Strachey. (Pp. 133. 10s. 6d.) London: Imago Publishing Co. 1949.

When *Three Essays* made its first appearance forty years ago it may be said to have rivalled the work of Galileo in the storm of indignation, hostility, and recrimination which it evoked. It is remarkable that in spite of this it has been translated into most languages, and reached a fourth German edition by 1920. The book was the basis of a large part of Freudian teaching, and from its

conclusions, with the doctrines set out in *The Interpretation of Dreams*, there developed the theory and practice of psycho-analysis. Not only this, but the startling conclusions on the theory of sexuality have now become fairly generally accepted. This excellent new English translation is most welcome, for if the Freudian doctrine is to be learnt by the neophyte or appraised by the experienced psychotherapist (of whatever school) it is essential for him to refer to originals without the labour of pursuing the German text.

The first essay gives us a general conspectus of the sexual perversions. The second shows how psycho-analysis led to the discovery that sexuality did not start at puberty, and that any previous manifestations were not necessarily pathological. On the contrary, it revealed a real infantile sexual life in every child, which was repressed and forgotten about the age of 5 and remained latent, except for occasional outbursts, till the onset of puberty. This infantile sexuality is polymorpho-perverse, and its manifestations correspond to the temporary dominance of the various erotogenous zones—oral, anal, urethral, and phallic. The third essay shows how adult perversions and many neuroses, especially hysteria, could be explained by repressions, deviations, and irregular development of these various phases. A useful summary by the author recapitulates his discoveries and the conclusions which he draws from them.

R. G. GORDON.

The fourth edition of *Manual of Clinical Laboratory Methods*, by Opal E. Hepler (pp. 387; illustrated; £2 5s.; Oxford: Blackwell Scientific Publications, 1949), intended primarily for laboratory technicians and medical students, is much larger than its forerunners. About half the book is allotted to investigations in chemical pathology, and the techniques used in haematology, bacteriology, and serology are described in fairly extensive detail. There are also short articles on pregnancy tests, tissue sectioning, allergy extracts, basal metabolism, and even electrocardiography. For most investigations one method only is described, though two or more are given for important determinations. The methods chosen are usually those popular in Britain, but a notable omission is an account of the use of the spectroscope for the detection of porphyrin, urobilin, etc. Neither is the useful property of fluorescence in ultra-violet light described. The unusual features of the book are its format and arrangement. The large size of its pages has allowed the diagrams and nomograms to be drawn on a large scale and comprehensive tables to be made. Many of the tests are arranged under a series of headings; though the use of a uniform order of description is good, one cannot avoid feeling that the author has got into difficulties in allotting numbers and letters to the various sections and headings. Nor has sufficient attention been given to the spacing between different sections, and it is not easy to find where one subject ends and another begins. There are some useful nomograms for determining the red cell indices, and there are eight good colour plates showing the maturation of blood cells and development of malaria parasites, though these were prepared too early to allow the inclusion of the tissue forms of the latter. British readers may find a few of the words and phrases used in the text unfamiliar, and they may be a little surprised by such words as "urinalysis" and "dark-field examination," and by the instruction to fill a 500-ml. "graduate" with, say, alcohol. The distinguishing characteristics of the book are its explicit technical instructions and the attention it draws to sources of error. Its introduction into laboratories may well improve the standard of work carried out in them: if references were given it would have even wider appeal.

Schafer's Essentials of Histology (15th ed.; edited by H. M. Carleton, B.Sc., and E. H. Leach, B.Sc.; pp. 655; 25s.; London: Longmans, Green) is so well known by students of medicine and biology that little need be said about it. The general arrangement and character of the work show little alteration, but there are many minor changes throughout. It is unfortunate that the account of the circulation in the kidney does not include a more direct reference to the supply of blood to the medulla, which may be physiologically important as a shunt mechanism. As a foundation for the study of physiology and of pathology the book is probably unsurpassed, and its reasonable price is a further attraction.

PAS AND STREPTOMYCIN

We publish on page 1521 an important statement from the Tuberculosis Research Unit of the Medical Research Council. It is to the effect that in the treatment of pulmonary tuberculosis of a certain type the administration of para-aminosalicylic acid (PAS) in addition to streptomycin has unmistakably reduced the frequency with which the patient's tubercle bacillus acquires resistance to streptomycin. Acquired resistance is the bugbear of all streptomycin treatment, and, as was pointed out recently in these columns (November 12, p. 1098), it may have peculiarly disastrous results in this disease. Recent reports[1] from the U.S.A. provide interesting information about factors affecting the development of drug resistance. There is a clear relationship with the type of lesion, frank caseation or cavity formation favouring the emergence of resistant organisms. The system of dosage also affects it, the main point being that intermittent treatment, such as the administration of a single 1-g. dose at intervals of three days or more, tends to prevent or at least delay the development of resistance. The effect of the size and number of doses during continuous treatment is more complex, but it seems that large doses, such as 3 g. daily, tend to produce highly resistant bacilli and smaller doses bacilli of intermediate degrees of resistance, most of which nevertheless are probably unaffected by further treatment. Shortening the course from 120 to 42 days had been expected to obviate drug resistance but has apparently not done so.

The advent of PAS has greatly altered the whole aspect of this problem. This substance was first shown by Lehmann[2 3] to have a pronounced action on tubercle bacilli *in vitro*, and both animal experiments and later clinical trial confirmed that this action is also exerted in the body. Feldman, Karlson, and Hinshaw[4] reported over two years ago that the drug is well tolerated by guinea-pigs and has a pronounced suppressive effect on experimental tuberculosis in these animals. Youmans and his colleagues[5] confirmed this finding in mice, though they note that PAS is inferior to streptomycin. There have been several accounts of preliminary clinical trials in human tuberculosis by Lehmann himself and others, and various forms of the disease have been treated with, on the whole, encouraging results.

There seems to be little doubt that the most valuable use for PAS will be to reinforce the therapeutic action of streptomycin. That the two drugs together exert a greater effect than either alone, apart from the advantage that the sensitivity of the bacillus to streptomycin tends to be preserved, seems evident from the recent experiments of Karlson and Feldman.[6] In guinea-pigs treated in four different ways the smallest traces of disease—represented by an infection index of 2·8—were found in animals given 4% of PAS in the diet and 2 mg. of streptomycin daily. A dose of 2 mg. of streptomycin alone gave an index of 18.2, and 6 mg. one of 3.6: thus a larger dose of streptomycin was slightly inferior in effect to the combined treatment. The index in the case of the animals given PAS alone was 27.0 and in that of the untreated controls 85.5. Clinical trial of the two drugs given together has not proceeded far enough for it to be asserted that its direct therapeutic effect is superior to that of streptomycin alone, but American workers are convinced of its value in preventing the emergence of drug resistance. Combined therapy of several kinds has been under trial in the nation-wide studies controlled by the Veterans' Administration in the U.S.A., and the conclusion reached is as definite as that in the Medical Research Council statement published to-day. Among other combined treatments, streptomycin with "promizole" did not reduce the incidence of drug resistance. Streptomycin and PAS, on the other hand, gave rise in one series of treated cases to only three resistant cultures from 26 patients (12%), whereas in patients given only streptomycin the proportion of resistant organisms isolated at the same stage of treatment was about 50%.[1]

These and similar observations have led the authorities controlling the American Veterans' Administration research programme to take an important decision: of the various methods of treatment tested in cases selected at random from patients considered suitable for treatment, all those employing streptomycin alone in whatever doses or for whatever period have been abandoned.[7] The three regimens henceforth to be tested are all 120-day courses, in each of which 12 g. of PAS is given daily together with either 1 g. of streptomycin daily, 1 g. of dihydrostreptomycin daily, or 1 g. of streptomycin twice weekly. It is clear from this decision, more than from any published data on the effects of such treatment, that American opinion is convinced of the value and necessity of using PAS in conjunction with streptomycin.

PAS is given by the mouth with or after meals, the dosage adopted in the U.S.A. being four daily doses of 3 g. each. It is believed to be free from any dangerous toxic effects—unless the leucopenia sometimes observed proves other than temporary—but in a large proportion of patients it causes nausea, vomiting, and diarrhoea. This has been the main difficulty in its administration: Pfuetze and Pyle[8] found that only half their patients could tolerate a daily dose of 10 g. Enteric-coated capsules do not obviate this difficulty, but the addition of sodium bicarbonate and a flavouring agent has been found helpful. The difficulty may eventually be overcome by devising a method of parenteral administration. PAS given subcutaneously in the form of its sodium salt, according to Feldman and Karlson,[9] exerts full therapeutic effect on tuberculosis in guinea-pigs, but the injections cause very severe local reactions. Possibly the final solution may prove to be the use of the chemical compound of PAS and streptomycin described by Hobby.[1] This is a freely soluble substance to which tubercle bacilli are in general more sensitive *in vitro* than to a corresponding amount of streptomycin itself. Strains resistant to it could not be produced *in vitro*. It is more effective than streptomycin in the treatment of tuberculosis in mice, and repeated injections at the same site are said to be non-irritating. More information about this substance will be awaited with much interest. A further fact to be borne in mind is that tubercle bacilli can acquire resistance to PAS itself, at least if this is given alone. Karlson and his colleagues[10] tested cultures isolated from the same patient before and after treatment; the sensitivity of the bacilli to PAS rose from 0.024 to 3.2 mg. per 100 ml. As would be expected, the resistant variant produced disease in guinea-pigs which did not respond to treatment.

THE VIRUS THEORY OF CANCER

There is general agreement that the inciting cause of cancer may be any of a number of agents, such as *x* rays or chemical carcinogens. But having started the cancer off they cease to operate, and it is then necessary to find the continuing cause. About the nature of this continuing cause there is much disagreement. Two main theories have been put forward to account for the unrestrained growth of the cells forming a neoplasm. According to the virus theory there was in the cell long before any neoplastic change occurred a virus which was living quietly in symbiosis with its host until the balance was disturbed by the inciting cause. According to the other theory the inciting cause provokes a somatic cell mutation: this is pure speculation, but appeals intuitively to some. The virus hypothesis can be experimentally proved in a small number of instances, notably in the case of the Rous fowl sarcoma, but from the great majority of tumours no virus can be separated by filtration. Those who support the theory maintain that this failure to isolate a virus from most tumours is due to technical difficulties, for it can be shown with other virus suspensions that if only a few virus particles are present they are adsorbed in the pores of the filter and do not appear in the filtrate. Professor W. E. Gye, who was director of the Imperial Cancer Research Fund laboratories at Mill Hill from 1936 until his retirement earlier this year, is a firm believer in the virus theory, and he has been active for most of his professional life in collecting evidence to support this belief. About two years ago Dr. James Craigie, well known for his studies on bacteria and viruses, joined him at the Fund laboratories, and together they initiated a new series of experiments. Some account of this work, in which their colleagues Miss Ida Mann and Dr. A. M. Begg collaborated, has already been published,[1 2] and comment on it has appeared in this *Journal*.[3] In Gye's opinion these new experiments offer definite proof of the virus theory. However, this opinion has been challenged by Dr. C. H. Andrewes in his Imperial Cancer Research Fund lecture delivered at the Royal College of Surgeons on November 29 and shortly to be published in this *Journal*. Andrewes spoke as a believer in the virus theory of cancer and described in some detail the grounds for his belief, at the same time stating why, despite the new evidence which Gye and his colleagues have brought forward, he still cannot exchange the arduous exercise of faith for the serenity of complete certainty.

The experiments described by Gye seem to show that typical non-filterable mouse tumours can in fact be transmitted by agents other than intact cells. Since it has many times been demonstrated that the presence of a virus in these tumours cannot be revealed by filtration other methods of virus detection were tried. It was found that the tumours could be minced and frozen at −79° C. for long periods and yet, after thawing and injection into suitable animals, they provoked new tumours. It is argued that no living cell could have survived this treatment; moreover, mouse-embryo tissue which will provoke embryomas on injection was rendered quite inert by such freezing. Unfortunately there is no information about the relative potency of the two preparations in causing new growths before freezing, and without this it is possible to argue that a few cells survived in both instances, but that for the production of embryomas more cells were needed than for the initiation of a new tumour: freezing had reduced the number of viable cells below the minimum necessary for the one but not below the minimum for the other. Another series of experiments has shown that tumour tissue may

[1] *Brit. J. Cancer*, 1949, 3, 259.
[2] *British Medical Journal*, 1949, 1, 511.
[3] Ibid., 1949, 1, 531.

be dried from the frozen state and yet initiate tumours on re-hydration and injection into suitable animals. It is very unlikely that living cells can survive such treatment, but it is not absolutely certain that every single living cell was destroyed. In both instances it is lack of quantitative information that hinders assessment of the significance of the results.

Dr. James Craigie, who has succeeded Professor Gye as director of the Imperial Cancer Research Fund laboratories, is cautious in his remarks about the new evidence which he and his colleagues have brought forward. In the Imperial Cancer Research Fund Lecture given at the Royal College of Surgeons on November 22, and published in the opening pages of this issue, he asserts that no real progress can be made in solving the problem of whether the continuous cause of transplantable tumours is a coexistent virus until "an adequate foundation of quantitative data has been laid down." The evidence for or against will, he thinks, inevitably emerge if work is conducted towards this end. Craigie has therefore begun a series of studies which may well revolutionize cancer research. To the casual reader the preliminary work may seem mundane, for it is concerned with designs for tissue mincers, the fluids which are best for suspending the minced tissue, the way in which minced tissue may be stored and dried, and the methods of comparing the activity of different tumour preparations. But all these are points of fundamental importance if cancer research is to be put on a quantitative basis. What Craigie is now doing is to bring the more refined methods of studying viruses into the field of cancer research. Immediately ahead there lies enough work for a generation.

THE SHORT OESOPHAGUS AND HIATUS HERNIA

The condition often described as the short oesophagus is a form of hernia which may simulate a variety of clinical syndromes. The essential lesion is incompetence of the diaphragmatic oesophageal hiatus with herniation of the cardiac portion of the stomach above the diaphragm. This may sometimes pass upwards as a pouch of stomach alongside the oesophagus; in other cases the upper part of the stomach forms the hernia, leaving the thoracic oesophagus either with a normal length and tortuous appearance or apparently shortened. It is doubtful if it is correct to consider the three subdivisions as separate entities: the para-oesophageal hernia may become the oesophago-gastric, and this in turn may develop a shortened oesophagus. All three varieties are best considered under the general term of diaphragmatic oesophageal hiatus hernia. The final two words are short and alliterative, and by common usage connote the site of the herniation. The objection to describing one variety as the short oesophagus is that it implies an aetiological significance which is probably not justified. Congenital shortening of the oesophagus undoubtedly can occur, and probably accounts for the rare cases of oesophageal ulceration and stricture in children.

The majority of cases of hiatus hernia, with or without apparent shortening of the oesophagus, occur in middle-aged and elderly patients, in whom the primary defect is a weakness of an abdominal orifice. Such a weakness develops more commonly in the sthenic individual and is aggravated by the same factors which may lead to herniation elsewhere from the abdomen. It is likely that secondary shortening of the oesophagus may result from spasm of the longitudinal coat of the oesophagus: this might occur from direct irritation of the oesophagus by regurgitation of acid gastric contents causing peptic oesophagitis. If this should lead to peptic ulcer of the oesophagus shortening may then develop from cicatricial contracture, as is seen with "purse-stringing" of the lesser curve from gastric ulceration. It must, however, be mentioned that Gilbert, Dey, and Rall[1] have thought that shortening of the oesophagus could be due to a vago-vagal reflex from an intra-abdominal lesion such as cholelithiasis or duodenal ulcer, either of which are not uncommonly found with a hiatus hernia. Experiments on dogs have shown that vagal stimulation may cause oesophageal shortening, and the same result could be obtained by stimulation of the peritoneum or distension of the gall-bladder.

Dysphagia with hiatus hernia signifies severe oesophagitis or peptic ulceration. Only five patients were without this symptom in the series of 31 cases admitted to the Western Infirmary, Glasgow, during the past ten years and reported in last week's *Journal* (p. 1443) by Drs. J. B. Rennie, F. T. Land, and S. D. S. Park. Dysphagia is a relatively uncommon symptom with hiatus hernia, many of which may cause few or even no symptoms. Radloff and King[2] found dysphagia in 22% of their cases of hiatus hernia. The Glasgow series probably does not represent the total number of patients with this condition seen at the Western Infirmary, but essentially those with dysphagia as a presenting symptom. The diagnosis of hiatus hernia requires special radiological technique, and it is the responsibility of the clinician to remind the radiologist of its likelihood, for routine barium meals in a busy department may fail to demonstrate the herniation. The symptoms are protean and include unexplained haematemesis, obscure cases of anaemia, dyspepsia of all degrees—from heartburn to intense boring retrosternal pain after meals—pain simulating angina but occurring at rest or after meals, breathlessness, and cough. These symptoms may result from

[1] *J. Amer. med. Ass.*, 1946, 132, 132.

associated peptic oesophagitis or from the mechanical effects of the hernia. The finding of a hiatus hernia in an elderly patient may occasionally be misleading and direct attention away from a more important intra-abdominal condition. Factors causing a rise in intra-abdominal pressure may lead to incompetence at the cardia. Rennie and his colleagues draw attention to pregnancy as a possible precipitating cause of peptic oesophagitis or stricture. Lewis's[3] case of oesophagitis caused by an indwelling gastric tube suggests that another mechanism might account for the three post-operative cases included in the Glasgow series. Post-operative regurgitation of gastric contents, possibly seeping round a gastric tube in a supine, comatose patient, might cause an acute peptic oesophagitis.

Although patients with hiatus hernia and shortened oesophagus may be able to lead reasonably comfortable lives if they select their food with care and chew it well, nevertheless surgery can offer relief in many cases. The experience of Allison[4] with transthoracic repair of the hiatus hernia is particularly encouraging; in cases with much shortening and stenosis of the lower oesophagus local resection and anastomosis to the jejunum has been successfully performed.

PREGNANCY IN DIABETICS

Many workers have shown that the pattern of production of chorionic gonadotrophin (C.G.) in normal pregnancies, as reflected by its level in the blood or its excretion in the urine, is remarkably uniform. After conception the hormone rapidly increases in amount, so that between the fortieth and eightieth days of pregnancy a peak excretion occurs of 25,000–30,000 i.u. in 24 hours. There follows a rapid fall, and from the hundredth day of gestation until parturition about 4,000–10,000 i.u. are excreted each 24 hours. Departures from the norm have been claimed to occur with statistically significant frequency in pregnancies complicated by diabetes and by late toxaemia. For these observations credit is principally due to Priscilla White and to O.W. and G. van S. Smith, who have elaborated a complex theory of hormonal imbalance in a long series of papers. The characteristics of this imbalance are said to be deficiencies in production of oestrogen and progesterone by the placenta, with a reciprocal rise in C.G. levels, the latter being explained as a failure of "utilization" of this hormone by the placenta. White[1] found such an imbalance in more than 75% of patients in a consecutive series of 300 pregnant diabetics. By treatment with oestrogen and progesterone she obtained a foetal survival rate of 90%, compared with only 47% for an untreated control group (which, it should be noted, was one-third less in size), and the incidence of pre-eclampsia was reduced from 50% to 5%. The effectiveness of the treatment was ascribed to its having restored the hormone balance to normal. The Smiths[2] have maintained that late pregnancy toxaemia, which occurs frequently in diabetics, is always preceded by the hormonal imbalance mentioned above, and they have obtained encouraging results by the prophylactic administration of stilboestrol to patients whose previous pregnancies had been complicated by toxaemias. On the other hand, by no means all workers have been able to confirm these findings, either in so far as they relate to the hormone levels in blood and urine or to the effects of treatment with oestrogens. Indeed, Snaith[3] has recently reported an unexpectedly high incidence of toxaemia in a group of patients with habitual abortion treated with oestrogens, even though the proportion of live births in the treated patients was higher than would have been expected on a chance basis.

Elsewhere in this issue Dr. J. A. Loraine reports the results of his studies on the excretion of chorionic gonadotrophin by pregnant diabetic women. This careful work clears up at least some of the obscurities in the endocrinology of obstetrics, for it leaves no doubt of the existence of increased C.G. excretion in some cases of diabetic pregnancy, though the absence of a departure from normal in no less than eight out of fourteen cases is noteworthy. That the administration of stilboestrol depresses the level of C.G excretion in both normal and diabetic pregnancies also appears to have been established beyond doubt. However, the important additional information provided by these studies is that in spite of continued administration of stilboestrol, even in increasing dosage, the C.G. excretion soon rises to, and may indeed surpass, its previous levels. Temporary interruption of stilboestrol treatment seems to restore the sensitivity of the response, at least for a time. It might, therefore, be a wise plan to administer stilboestrol in interrupted courses to these patients, if it can be accepted that depression of the elevated C.G. excretion is an object to be desired. Dr. Loraine's paper provides no evidence on this last point, since most of his patients were delivered before term by caesarean section. In no case was the baby characteristically oversize, and in one case at least mild pre-eclampsia developed while the patient was actually receiving stilboestrol. Clearer understanding of the underlying causes of these abnormalities will eventually lead to improved methods for reducing the foetal mortality and preventing the onset of late toxaemia in diabetic pregnancies.

ANIMAL EXPERIMENTS

It is constantly being asserted by anti-vivisectionist societies that animal experiments have not made any contribution to medical progress. Little attempt is made to counter this distortion of fact, for the publications and lectures of the Research Defence Society, excellent though they are, do not reach the general public. Another organization doing useful work is the Universities Federation for Animal Welfare: its handbook, *The Care and Management of Laboratory Animals*, was reviewed in the *Journal* some months ago (July 20, p. 20), and an annotation on laboratory animals appeared in the same issue (p. 26). The Federation's latest publication[1] is entitled *How to Befriend Laboratory Animals*. The sincerity of the author is obvious, and the problem is looked at from many sides by one

[1] *Penn. med. J.*, 1947, 50, 705.
[2] *J. clin. Endocrinol.*, 1941, 1, 461.
[3] Report of the Sixth Annual Conference on Infertility in the *British Medical Journal*, 1949, 2, 809.

deeply sensitive to the infliction of unnecessary pain on either man or beast. Not everyone will agree that "there is no reason except prejudice for preferring that an animal rather than a random human being should suffer pain," but nevertheless the general conclusions about the value of animal experiments are stated in unequivocal language. "Anyone who says that medicine, in as far as it has become scientific, does not depend on physiology, pathology, or pharmacology, or that these sciences could have progressed so far as they have without experiments on animals, is so obviously talking through his hat that he puts himself out of court and wrecks his chance of being taken seriously."

While justifying the need for animal experiments, the author of this pamphlet makes valuable criticisms. The improvement of the status of the animal attendant is important. Too often the position of "animal boy" is a despised one, and yet the care of animals requires very special abilities, and the success of experimental work largely depends on the handling of the animals before and after their time in the laboratory. Need for increased expenditure on animal accommodation is also stressed and should be considered in future schemes of development. This is particularly important in view of the need for developing techniques for the study of function by long-term experiments uncomplicated by anaesthesia. Inclusion of a veterinary surgeon among the Home Office inspectors is also an excellent suggestion. The author also does good service in pointing out the irrational attitude towards certain favoured species, notably dogs. It would seem that if the dog were exempt from experiment the causation of pain to less popular animals, such as rats, would be a matter of much less concern. No good reason exists for making such a distinction. The scientist, who does not wish to cause unnecessary pain to either dog or rat, prefers to choose his species for its suitability to his problem and not on emotional grounds. Choice of experimental animal is referred to elsewhere in this issue by Professor Samson Wright, who draws attention in a book review to the great difficulty of obtaining dogs and cats in sufficient numbers. This is undoubtedly having a deleterious effect on both teaching and research in physiology and, ultimately, on medical progress.

The present position is ridiculous. Parliament has recognized the value of animal experiments in medical research, and through licences issued by the Home Office gives protection to those doing the work. The University Grants Committee and the Medical Research Council, financed by the taxpayer and responsible to the Government, make money available for the purchase of animals which are both very scarce and very expensive. At the same time the police, under Home Office guidance and also financed by the taxpayer, assist in the collection and destruction of tens of thousands of stray animals every year, with the express aim that these shall not become available for medical research. This is both hypocritical and wasteful. Professor Samson Wright suggests an official approach by the Physiological Society to the Home Office, but it would seem that the approach might have more chance of success if supported by other bodies with wider interests. Any Government must hesitate about introducing legislation which might lose votes. But it is possible that the risk is exaggerated. A few years ago diphtheria immunization was a similar controversial subject, and now, thanks to courageous action and a well-conducted campaign of public enlightenment, it has proved to be a great boon to the health of the public.

MEDICAL PRACTICES ADVISORY BUREAU

A year ago the B.M.A. set up the Medical Practices Advisory Bureau to help doctors enter medical practice. Most of its work has been done in the field of general practice, since hospital appointments are advertised in the Press and applicants compete for them as before. But it has nevertheless been able to advise many doctors in finding suitable posts outside general practice. The most popular way of entering general practice is still by means of assistantship, and the Bureau has performed a valuable service in bringing together principals and assistants.

An unexpected finding of the Bureau's first year of work is that entry into general practice is easier than many believe, though lack of suitable housing is an obstacle in some places where an assistant or partner is sought. In general there is no difficulty in entering practice for a young man with ordinary qualifications who does not mind where he practises and is willing to accept the remuneration attached to the bottom rung of the ladder. Increasing age is a hindrance as in other walks of life, and doctors over 40 are certainly handicapped by their years. It is also regrettably true that refugees from foreign countries, among whom there are many doctors, have greater difficulty in finding openings than their British colleagues—a situation confined neither to the medical profession nor to Britain. But perhaps the greatest problem that the Bureau has had to contend with arises from the "territorial demands" of the applicants, who naturally enough often specify certain areas of the country where they wish to practise. In most cases these areas already have sufficient doctors. Even so, the Bureau has had some disappointing experiences. On several occasions it has informed over 100 doctors of a vacancy that seemed to conform with their desires, yet only a dozen or so have applied. Recently, for instance, a principal in the Home Counties earning over £5,000 a year offered a one-third share of the practice after a preliminary assistantship of twelve months, the share rising to two-fifths in five years, and to 48% in ten years. A small modern house was available to rent at 30s. a week. The Bureau sent the details to more than 130 doctors: fewer than 20 responded.

Now that general practitioners are gaining experience of the Health Service many of them who a year ago were doubtful about taking assistants or partners are deciding to do so. At present the Bureau is filling about 50% of the vacancies referred to it, whereas nine months ago the figure was about 30%. Certainly the Bureau has found no evidence to support allegations that principals tend no longer to seek partners but prefer a succession of assistants. As the director said in his report[1]: "Contrary to expectation, there seems to be an increasing tendency for the retiring doctor to wish to preserve the practice as an entity by securing the introduction of a 'logical

[1] *British Medical Journal Supplement*, 1949, 2, 226.

successor' or by taking in a partner for a longer or shorter period."

The services of the Bureau are free to members of the B.M.A., and that doctors are finding it useful is clear from the steady increase in the numbers who seek its help. Its offices are at B.M.A. House in London, at 7, Drumsheugh Gardens, Edinburgh, and at 33, Cross Street, Manchester.

VITAMIN C AND BENZENE POISONING

Having observed that the symptoms of scurvy resembled those of benzene poisoning, Meyer[1] carried out the experiment of giving large amounts of ascorbic acid to guinea-pigs in order to find out if they became more resistant to benzene: he found that they did. Friemann[2] measured the output of ascorbic acid in the urine of men exposed to benzene fumes and found it reduced, and Forssman and Frykholm[3] observed signs of vitamin-C deficiency in the majority of 26 men exposed to benzene fumes, as compared with 23 men in the same industry who were not exposed to the fumes. The relation between vitamin-C deficiency and exposure to benzene fumes has now been more fully studied by Ekman,[4] who used large numbers of guinea-pigs and came to the following conclusions. Guinea-pigs exposed to benzene vapour daily lose weight and die. The administration of large amounts of ascorbic acid gives some protection, since they gain weight and not all of them die: to obtain complete protection the guinea-pigs must be given not only ascorbic acid but also cucumber or citrin. Cucumber contains large amounts of ascorbic acid oxidase, an enzyme which increases the breakdown of ascorbic acid in the body. Ekman considers that this oxidase accelerates the rate at which ascorbic acid breaks down the benzene molecule. Thus the protection given against benzene by ascorbic acid and cucumber depends on the fact that these agents furnish a means of destroying cyclic compounds like benzene.

PAIN OF VISCERAL ORIGIN

The mechanism of visceral pain is still a matter for speculation, mainly because it is difficult to obtain reliable factual information. The investigator is dependent on the patient's interpretation of the sensations which various manœuvres may provoke. Furthermore, the patient may be under the influence of drugs at the time or affected by a very natural anxiety. Nevertheless, certain constant responses have been noted, and recent investigations have added fresh information about visceral sensitivity. The earlier teaching that the viscera are at all times insensitive to ordinary stimuli must be modified in the light of the findings of Kinsella,[5] Brown,[6] and Bentley.[7] There can be no doubt that an inflamed or diseased area in a viscus can be tender to direct pressure, and even normal organs—for instance, the testes—may be sensitive. The pain is not well localized, due partly to the relatively small numbers of afferent nerves from the viscera and partly to the sensorium being uneducated to interpret these rare sensations. As a result, the tendency is to relate the pain to the embryonic position of the viscus. Bentley[8] has demonstrated that the afferent fibres travel via the splanchnic nerves, since he found that splanchnic block abolishes the tenderness of a peptic ulcer. Stretching or spasm of the muscle of the hollow organs of the abdomen causes pain which is mediated by the same nerves. Such pains may be associated with voluntary guarding, but not as a rule with true involuntary rigidity. This latter is largely dependent, as Morley showed, on irritation of the parietal peritoneum and, with acute local tenderness, is the most reliable sign of inflammation in the abdomen.

Though it seems clear that visceral and parietal irritation causes distinct sensations of pain carried by different nerves, the question remains whether there is a place for Mackenzie's old theories of the viscero-cutaneous reference of pain and of viscero-motor reflexes. So far as the abdomen is concerned there is little need to invoke these hypotheses, except perhaps for the unilateral rigidity of renal colic. But the radiation of pain in angina pectoris is difficult to explain otherwise, and the concept of an irritable focus in the spinal cord has recently been reintroduced to account for certain ill-understood painful states in the upper limbs.[9] Though much remains to be learned, it is now possible to interpret with fair accuracy pain and tenderness due to visceral disease.

MEDICINE, 1900–50

Anyone born in the year 1900 probably likes to think of himself as a child of the twentieth century. But according to the Astronomer Royal he is not; he belongs apparently to the nineteenth century. The cause of the disappointment is that there was no A.D. 0, or at least no A.D. 0 has been admitted by the chronologists. The error having started so far back, no one has yet had the common sense to say outright that the first century by some mishap contained only 99 years. If this convenient and charming fiction had been adopted there would not have occurred at intervals of 50 years since pedantic discussions about the beginning and end of centuries. According to *The Times*[10] Kaiser Wilhelm II declared firmly that 1899 was the last year of the nineteenth century. To-day we find ourselves in the much better company of France, whose Ministry of Justice has decreed that on Sunday, January 1, 1950, France will enter the second half of the twentieth century.[11] On the reasonable assumption that 50,000,000 logical Frenchmen cannot be wrong, this *Journal* in its issue of January 7 will celebrate the first half of the twentieth century by publishing a special symposium on the theme "Fifty Years of Medicine." It will do that firm in the conviction that at least no one will hesitate to celebrate January 1, A.D. 2000, as a remarkable date in the history of the human race.

Dr. Howard Nicholson will deliver the Goulstonian Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, January 10 and 12, at 5 p.m. His subject is "Suppurative Pneumonia."

TREATMENT OF PULMONARY TUBERCULOSIS WITH PARA-AMINOSALICYLIC ACID AND STREPTOMYCIN

PRELIMINARY REPORT

A clinical trial of *p*-aminosalicylic acid (PAS) and streptomycin in pulmonary tuberculosis was undertaken in 1948 by the Medical Research Council, with the co-operation of the British Tuberculosis Association. The trial is not yet completed, but certain results already obtained are of such importance that the joint committee responsible for guiding the trial has decided to issue the following preliminary statement.

A major disadvantage in the use of streptomycin is that the period of effective therapy is limited in many patients by the emergence of streptomycin-resistant strains of tubercle bacilli after five or more weeks of treatment. It has been thought by many workers that the addition of another tuberculostatic agent might be sufficient to suppress the resistant strains, which in the initial phases are present in very small numbers; published reports on a few cases treated with PAS and streptomycin have been encouraging. The present investigation was planned to examine, by the method of controlled trial, the possibility that PAS has this property, and at the same time to assess the clinical effect of this drug alone and in combination with streptomycin. Accordingly, three treatment groups of over 50 cases each were observed: (*a*) PAS alone (20 g. of the sodium salt daily); (*b*) streptomycin alone (1 g. daily); and (*c*) both drugs together (20 g. of the sodium salt of PAS and 1 g. of streptomycin daily). The methods were similar to those employed in the first M.R.C. clinical trial of streptomycin in pulmonary tuberculosis (*British Medical Journal*, 1948, 2, 769), and the type of case was again defined as follows: acute rapidly progressive bilateral pulmonary tuberculosis, of recent development, unsuitable for collapse therapy, in young adults aged 15 to 30. After acceptance for the trial by a panel, patients were allocated to one of the three treatment groups by a method of random selection. The prescribed treatment was given for three months in each case. Clinicians and pathologists at eleven hospital centres have co-operated in this investigation, keeping uniform records, employing standard clinical and bacteriological procedures, and reporting results at regular intervals to the Council's Tuberculosis Research Unit, where the grouped results have been analysed.

For this well-defined type of case of pulmonary tuberculosis the trial has demonstrated unequivocally that the combination of PAS with streptomycin reduces considerably the risk of development of streptomycin-resistant strains of tubercle bacilli during the six months following the start of treatment. This conclusion is applicable so far only to the acute form of disease treated, and it remains to be seen whether the same results are obtainable in other forms of tuberculosis amenable to streptomycin therapy. Furthermore, the conclusion is applicable only to the large dose of PAS used; this dosage causes discomfort in some patients, and it has been agreed to find out, by further trials, whether smaller doses would achieve the same result. It must be stressed also that streptomycin is effective only in certain forms of tuberculosis, and the finding reported here must not be interpreted as indicating that a combination with another drug will be effective in those forms in which little result would be expected from streptomycin alone.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

ANALGESIA IN CHILDBIRTH

BY

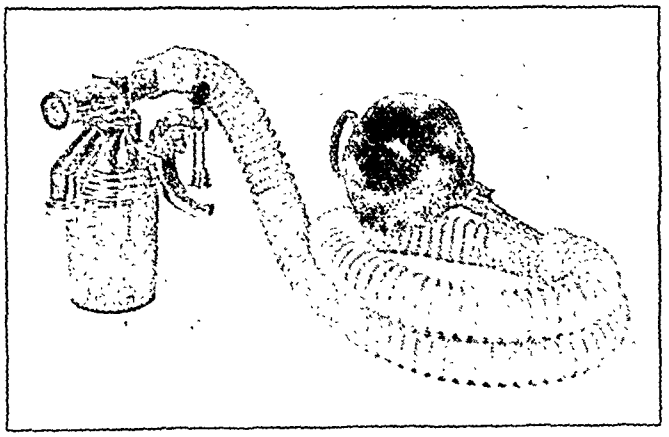
C. LANGTON HEWER, M.B., M.R.C.P., F.F.A.R.C.S.

Senior Anaesthetist, St. Bartholomew's Hospital

One of the first facts the medical student is taught when starting his course in obstetrics is that labour is a physiological function. It does not take him long to find out that however physiological the process may be it is usually accompanied by pain, which may be severe. To alleviate this pain without danger to mother or child has been a problem facing obstetricians and anaesthetists for over a century: now it is known that not only the mother but the baby benefits from painless childbirth.

Suggestion

It can safely be said that there is no known method of achieving general or local analgesia with drugs which may not either affect the course of labour or have some deleterious action on the mother or foetus. The only absolutely safe method of analgesia is that obtained by suggestion, one form of which is associated in this country with the name of Dr. Grantly Dick Read. The theoretical basis of this technique depends upon the assumption that fear causes a sympatheticotonia which makes the circular fibres of the cervical sphincter contract. In turn the longitudinal fibres of the upper uterine segment increase their tension to overcome the obstacle, and eventually the threshold of pain is crossed—"A tense woman means a tense cervix and a long and painful labour." This is probably an over-simplification of a complicated process, but there is no doubt that antenatal suggestion combined with relaxation at crucial times of the labour can work wonders with a co-operative patient. Unfortunately, this technique makes heavy demands on the doctor's time and patience, and in these days it is frequently impracticable.



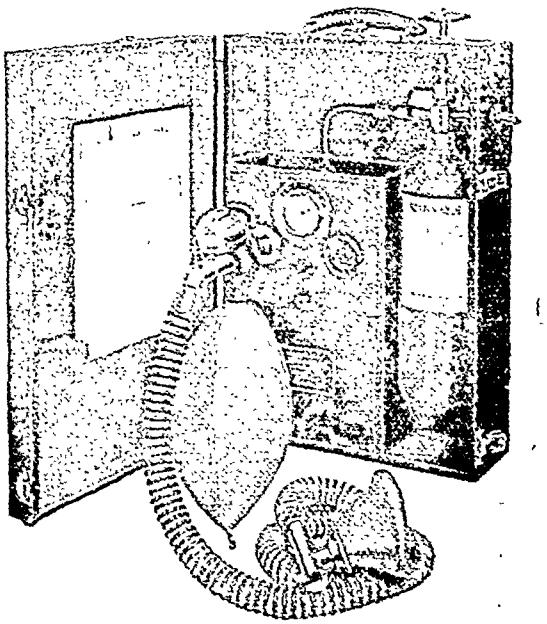
General Analgesia by Volatile Drugs: Chloroform

All volatile anaesthetics are to some extent analgesic when given in subnarcotic concentration, and most of them have been employed in this way in obstetrics. Chloroform analgesia has been in use for over a century, and the method is known as "à la reine," since John Snow practised it on Queen Victoria in 1853 during the birth of Prince Leopold. Chloroform analgesia is still widely used in rural areas of Great Britain, and general practitioners often fit up some type of Junker's apparatus and mask so that the patient

can obtain relief by hand-pumping. If chloroform must be used, Mennell's bottle is probably the safest auto-inhaler as it cannot be upset and is difficult to overfill. The tubes cannot be connected up wrongly, and the vapour concentration is normally insufficient to produce loss of consciousness. Capsules containing 20 min. (1.2 ml.) of chloroform have also been used; they could be crushed and placed under a mask to produce analgesia. Although it is probable that primary cardiac failure is less likely to occur during labour than at other times, chloroform is a toxic drug to both mother and child and its use is not to be encouraged.

Trichlorethylene

"Trilene" (purified trichlorethylene) has largely replaced chloroform as an analgesic in labour, since there is no doubt that it is less toxic to the liver and much less likely to cause primary cardiac failure. The most popular auto-inhaler in this country is Freedman's, a "draw-over" apparatus which delivers a vapour concentration of about 0.65% trilene in air. A hole near the facepiece must be covered by the patient's finger before trilene vapour can be inhaled, and thus acts as a safety device. This method is so convenient and reliable that an investigation was instituted by a committee of the Royal College of Obstetricians and Gynaecologists to see whether it could be used by unsupervised midwives. A study of 2,354 cases showed that the technique was most efficient, only 7% of the mothers being



The Freedman inhaler. (By permission of A. Charles King, Ltd.)

dissatisfied with the relief obtained. There was no evidence of increased risk to mother and child, but the committee did not recommend that legislation be passed for the method to be used without medical supervision. Other "draw-over" inhalers have been devised with which the vapour concentration can be varied to suit the individual patient, one of the simplest and most efficient being the "cyprane." The Oxford ether vaporizer can also be used for the same purpose; 7.5% on the ether calibration is equivalent to approximately 1.5% trilene.

Nitrous Oxide and Air

Nitrous oxide and air analgesia was popularized in 1933 by Minnitt, who adapted a McKesson oxygen-therapy apparatus for the purpose. Modern machines deliver about 45% nitrous oxide in air and work on the intermittent-flow principle, so that no gas escapes when the patient raises the facepiece. The air-hole normally covered by the patient's finger acts as a safety device. Gas and air should not be started too early in labour, and certainly not before the uterine contractions are causing discomfort. This will probably be at about five-shillings dilatation of the cervix. It is essential that inhalation be started at the very first warning of a pain. Between the pains, restful sleep is usually obtainable.

During the second stage of labour, inhalation of gas and air is stopped at the height of a pain and the patient asked to bear down while holding her breath. Further inhalations of the mixture can be taken after each effort. As the head

The Minnitt gas-air apparatus (portable model). The Chassar Moir attachment has been added to the delivery tube where it leaves the machine. With the cylinder valve open the 2.5-litre bag will fill with pure nitrous oxide—the first three or four breaths will be of nitrous oxide alone, after which the patient inhales the standard nitrous-oxide–air mixture. (By permission of A. Charles King, Ltd.)

is crowned, continuous inhalation should be given until the birth of the child, the patient being instructed not to bear down.

Pure nitrous-oxide–air analgesia administered from an approved apparatus is the only form of inhalation which may be given without medical supervision by midwives trained in its use. Since July, 1946, all pupil-midwives must take a course of instruction and be found proficient before enrolment as midwives. Nitrous-oxide–air analgesia is extremely safe and non-toxic apart from the slight risk of anoxia. The analgesia is, however, not always so complete as is desirable and the onset is rather slow. The former disadvantage can be overcome by adding a trace of trilene vapour to the mixture by some device such as a Rowbotham's bottle plugged into the circuit. A more rapid onset of analgesia can be obtained by starting each inhalation with two to three breaths of pure nitrous oxide followed by the gas-air mixture. A Chassar Moir attachment enables this to be done. It must, however, be clearly understood that any modifications to standard machines disqualify midwives from using them without supervision. The weight and bulk of the necessary apparatus constitute a definite disadvantage when gas-and-air analgesia is used in domiciliary practice. In addition to Minnitt's apparatus certain other types of intermittent-flow machines, such as the "Amwell" and the "Jecta," are recognized as safe for use by midwives.

Nitrous Oxide and Oxygen

The substitution of oxygen for air diminishes the risk of anoxia but renders the method impracticable for midwives and increases the bulk and weight of the apparatus. It is,

however, probably the safest form of inhalation analgesia for obstetrics and tends to shorten the course of labour by increasing the force of the uterine contractions. During the birth of the child a brief period of anaesthesia is easily obtained, but some obstetricians hold the view that from a psychological aspect it is better for the mother to retain consciousness. Light narcosis is desirable, however, should perineal sutures have to be inserted.

Analgesia by Non-volatile Drugs

In 1902 Von Steinbüchel and Gauss introduced "twilight sleep," which consisted of an initial injection of morphine and scopolamine followed by supplementary doses of scopolamine alone. Some analgesia and considerable amnesia resulted, but the frequent prolongation of labour resulting in the birth of a narcotized baby soon diminished its popularity. Most obstetricians now feel that morphine and its derivatives should seldom be used before the birth of the child.

The many non-volatile drugs which have been tried as substitutes for morphine include rectal paraldehyde and bromethol ("avertin"), and oral barbiturates such as pentobarbital ("nembutal"). More recently pethidine and physeptone have been employed, but unfortunately all these drugs tend to diminish uterine contractions and to depress the infant's respiration. It is impossible in this article to give details of the various techniques, or even to mention the many combinations of drugs which have been tried.

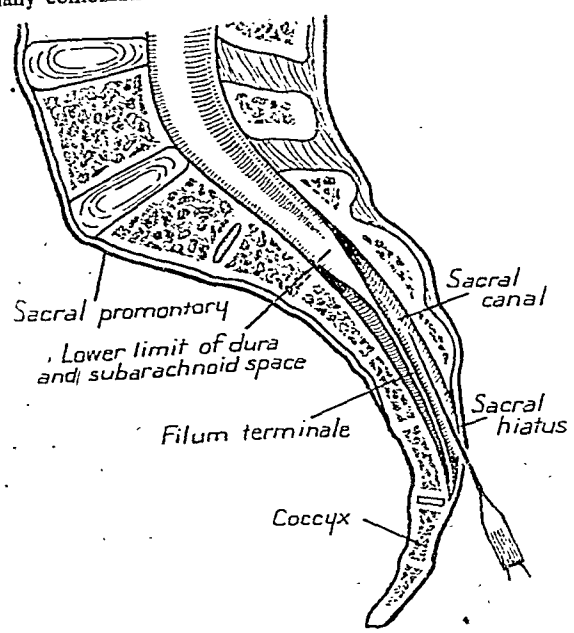


Diagram to illustrate the principle of caudal analgesia. The analgesic solution is injected through the sacral hiatus to render the nerves in the sacral canal insensitive, but remains outside the dural sac.

Intravenous procaine has also been used, and is said to be satisfactory. It is injected as a slow intravenous drip in a dilution of 1% in 5% aqueous glucose solution. It should be noted that it is unwise to exceed the rate of injection of 20 mg. of procaine per minute, or tachycardia, muscular twitching, and finally convulsions may ensue.

Local Analgesia

In order to be successful local analgesia for childbirth must obviate the pain both of the uterine contractions and of the dilatation of the birth canal. The method known as fractional caudal block has come to the front recently, and extremely good results are claimed for it. Very briefly, the technique consists in the insertion of a malleable needle or a ureteric catheter through the sacral hiatus into the caudal canal and injecting at intervals an analgesic solution such as 1% procaine. It should be clearly realized that this technique alters the whole course of labour. The patient has no urge to bear down or to use her abdominal muscles in the second stage, so that this is usually prolonged, while interference with the normal flexion of the head and rotation of the occiput result in an unusually high proportion of occipito-posterior presentations. The incidence of forceps deliveries is also increased. The insertion of the needle may prove difficult or impossible, particularly in fat patients, and inadvertent spinal block is a possible complication. Furthermore, sepsis and broken needles are not unknown. It will therefore be seen that the method demands a skilled team working in hospital, and it is outside the scope of the general practitioner. In an emergency some relief can be obtained from the pain of stretched tissues by infiltration on each side of the midline half-way between the anus and the edge of the perineum.

Spinal analgesia has been given a good trial, and, though it still has some advocates, the general feeling is that it is unsatisfactory for labour. There would seem to be an overaction of the circular fibres of the uterus combined with underaction of the longitudinal muscle, so that the organ contracts violently with diminished expulsive power. This would appear to be borne out by the fact that spinal block is frequently successful in the treatment of post-partum haemorrhage due to uterine atony.

Conclusions

From the foregoing remarks it will be obvious that there is an almost infinite choice in the possible techniques of analgesia for childbirth. There are bound to be considerable differences of opinion about their relative merits, but my own views are as follows:

(1) If an experienced anaesthetist is available, the safest and best method is nitrous-oxide–oxygen inhalation, intermittent during the pains of the late first and second stages and continuous during the birth of the child.

(2) If a general practitioner is present, the midwife can give trilene and air under his supervision with some type of auto-inhaler such as Freedman's. Alternatively, the gas-gas-air sequence can be used with the Chassar Moir attachment to a Minnitt's apparatus.

(3) If only the midwife is present, inhalation of a gas-air mixture from an approved machine is the only permissible method.

(4) If the delivery is taking place in the service of an obstetrical unit at a large hospital some local technique such as fractional caudal block may prove excellent.

It should be mentioned that only normal labours in healthy mothers have been considered in this article. Pathological conditions may necessitate some modifications of the analgesic technique.

The Scientific Film Association is conducting for its information service a national survey of makers, owners, and users of scientific films. It would be glad to be informed of the name and address of the makers of such films, the gauge and running time, and a brief synopsis of contents. Particulars of the association's work may be obtained from the secretary at 4, Great Russell Street, London, W.C.1 (Telephone: MUSeum 2403).

BRITISH ORTHOPAEDIC ASSOCIATION

ANNUAL MEETING

The annual meeting of the British Orthopaedic Association was held at Bristol from October 13 to 15 under the presidency of Mr. S. A. S. Malkin (Nottingham).

Orthopaedic Surgery and Traumatic Surgery

A discussion on the relationship of orthopaedic surgery to traumatic surgery was opened by Mr. William Gissane (Birmingham). He said that 80% of patients were admitted to casualty departments because of accidents, and only 10% required reference to the medical or general surgical departments. The casualty department had often proved a barrier to prompt and effective treatment, and control of these departments might justly be claimed an orthopaedic commitment. Fractures provided but a small part of the work of accident services. Accident hospitals like that at Birmingham could be developed for a population of about two million people, and should receive at once, both on economic and on clinical grounds, injuries of a specialized nature. An accident unit should retain and develop its relationship with surgery as a whole, and every accident hospital should be attached to a teaching hospital. After preliminary experience in general surgery and full training in orthopaedic surgery, intending traumatic specialists should acquire at least the first principles of plastic surgery and thereafter gain practical knowledge of the work of a special accident unit.

Mr. E. A. Nicoll (Mansfield) said that traumatology was now practised in three ways: in conjunction with orthopaedics; as part of general surgery; and as a specialty in its own right, a status which was hardly yet justified, and which in any event was inseparable from an orthopaedic training. Better distribution of orthopaedic surgeons was required.

Mr. H. Osmond-Clarke (London) considered that accident units should usually be situated in general hospitals, maintaining close contact with teaching hospitals. Whether the surgeon confined himself to traumatic work or not, training in general and orthopaedic surgery was essential. Mr. Rainsford Mowlem (London) emphasized the importance of full co-operation in any traumatic unit between plastic and orthopaedic surgeons. Mr. R. H. Metcalfe (London) referred to one Metropolitan region in which registrars had been enabled to gain a varied experience by working in rotation through appointments in casualty departments, wards, consultative out-patient departments, and long-stay orthopaedic hospitals.

Mr. Bryan McFarland (Liverpool) considered that an accident unit should be within a general hospital, with an orthopaedic surgeon in charge. The co-operation of a plastic surgeon in the treatment of injuries and in the training of orthopaedic specialists was desirable. Miss M. Forrester-Brown (Bath) referred to the Ontario scheme of postal advice upon radiographs. The president hoped that this expedient would not be followed. Mr. H. Langston (Southampton) considered that Mr. Metcalfe's scheme for registrars was excellent, pending the formation of large accident units.

Mr. Norman Roberts (Liverpool) said that the accident unit should be situated in a general hospital. The casualty department should be controlled by the accident service and directed by the orthopaedic surgeon. Mr. J. C. Scott (Oxford) deplored the inadequate orthopaedic training of many traumatic surgeons. Mr. E. N. Wardle (Liverpool) regretted the frequent appointment of the most junior member of a general hospital staff to the casualty or accident department. Mr. Roland Barnes (Glasgow) advocated an accident unit under the control of the orthopaedic department in every teaching hospital.

Professor George Perkins (London) thought it was generally agreed that everyone practising orthopaedic or traumatic surgery must be properly trained, and also that traumatology was not to be encouraged as a specialty. The president took the same view and said that practical experience was more important than a special degree. The emphasis should be on training in general orthopaedic surgery, and thereafter on special training in the principles of plastic surgery and traumatology.

Lesions of the Lumbar Intervertebral Disk

Mr. J. Pennybacker (Oxford), on the basis of 800 cases, mentioned first the importance of differentiation from cases of neoplasm, which were often misleading in their symptoms, but in which the neurological signs were usually progressive. Occasionally radiographs would show scalloping of the vertebral bodies or increased width between the pedicles; lumbar puncture usually revealed an increased protein content of the cerebrospinal fluid, and as a rule myelography established the diagnosis. Other conditions which might cause difficulty in diagnosis were tuberculous arthritis, metastatic carcinoma, and spondylolisthesis.

No lesion was found at operation in 3% of cases. Naffziger's sign and pain on lumbar pressure with the patient prone were important diagnostic aids. Treatment should follow the lines of rest in bed, a plaster jacket for six weeks, and thereafter a corset, operation being reserved for cases which were resistant or in which there were frequent recurrences. Manipulation was dangerous. Exploration must be extensive, including the fourth and fifth lumbar and the first sacral roots without laminectomy; both sides should be explored and the theca opened. Arthrodesis was usually performed only if relief was incomplete.

Mr. E. N. Wardle (Liverpool) regarded retropulsion of a disk as secondary to loss of equilibrium of the whole spine and loss of elastic reaction in many disks. A plaster jacket, applied in head suspension, had given complete relief in 60% of cases. Mr. J. R. Armstrong (London) detailed the causes of operative failure. Sometimes there was no lesion, or, more often, exposure was at the wrong level or a midline disk lesion made disclosure difficult. A double lesion was found in about 20% of cases; a bilateral lesion might need exposure on both sides. In some cases insufficient removal might allow further protrusion; or a previously healthy disk might prolapse. In other cases a nerve root might be damaged or might become adherent; there might be arthritis of intervertebral joints. Arthrodesis at the time of the first operation he condemned as unnecessary. It increased the complications and danger, and demanded a more prolonged post-operative immobilization. Where it was necessary, arthrodesis could more conveniently be undertaken later; it was difficult to repeat an operation on a nerve root after an unsuccessful arthrodesis.

Other Subjects

A number of short papers were presented on a variety of subjects.

Protrusions of Cervical Disks.—Mr. G. L. Alexander (Bristol) referred first to nerve root compression. He ascribed the frequent involvement of the sixth and seventh cervical roots to their thickness; the eighth cervical root, also thick, escaped because its course was less oblique and it was less prone to stretching by cervical and shoulder movements. In cord compression the symptoms and signs were often confused; lumbar puncture seldom helped, but myelography might. Cord compression called for laminectomy and removal of the displaced material. Operative results were imperfect.

Lambotte.—Professor J. Verbrugge (Antwerp) painted a vivid picture of Monsieur Lambotte, an early pioneer of bone suture. At 85 this versatile and ingenious surgeon still operated occasionally.

Fractures of the Upper End of the Radius in Children.—Mr. C. C. Jeffrey (Birmingham) confined his remarks to fractures through the neck of the radius and separation of the upper epiphysis. Most were abduction injuries, the position of the forearm determining the direction of the tilt, which could be estimated before reduction by radiography in various positions of rotation. Closed reduction was performed by digital pressure on the radial head in an appropriate degree of rotation with adduction of the elbow. The late results were good provided the radial head had not been completely displaced. Occasional premature fusion was much more likely if there had been complete separation, and would lead to deformity of the head of the radius and limitation of movement.

Experimental Rupture of the Medial Ligament of the Knee.—Mr. E. A. Jack (Edinburgh) had studied the results of

AN ADVANCE IN PENICILLIN THERAPY

'AVLOPROCIL'

TRADE MARK

PROCAINE PENICILLIN G OILY INJECTION

(With 2% Aluminium Stearate)

'Avloprocil' contains the procaine salt of crystalline penicillin in oily suspension (300,000 units of penicillin per c.c.) and offers important advantages to both doctor and patient :—

Therapeutic blood levels of penicillin maintained for 36-48 hours or longer

Effective penicillin therapy achieved with a single daily injection

Administration comparatively free from irritation and pain

1 c.c. vials, in boxes of 10. 10 c.c. vials, singly and in boxes of 5.

Literature and further information available, on request, from your nearest I.C.I. Sales Office—London, Birmingham, Bristol, Manchester, Glasgow, Edinburgh, Belfast and Dublin

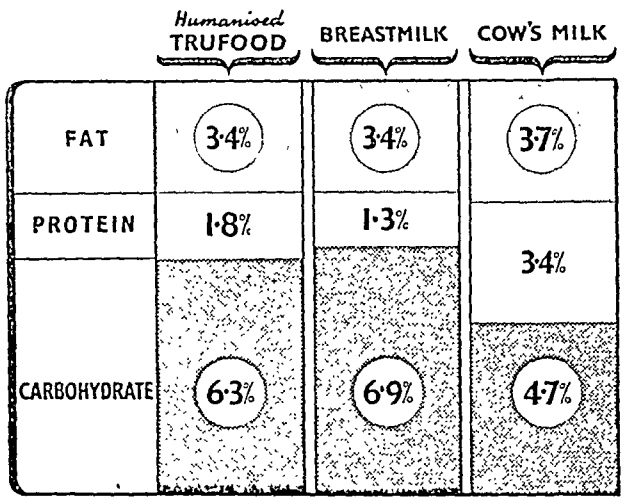
WHAT SHOULD BE THE CRITERION FOR AN INFANT MILK FOOD—



economy... or the provision of optimal nutrition?

Breast milk is the natural food for the human infant. Surely then, the indicated substitute is one which approximates most closely to breast milk?

In Humanised Trufood this close approximation to human milk is achieved by breaking down cow's milk into its constituents, and then re-assembling them in proportions similar to those of breast milk. Spray-drying at a low temperature then ensures that the fat is in a finely emulsified state. Naturally all this entails the use of costly technical processes.

The result is not a cheap product, but a reasonably priced one which has a balance of nutrients similar to that of breast milk: the protein, for instance, is similar not only in quantity but also in ratio of casein to soluble protein. For this reason Humanised Trufood is the indicated substitute in all cases where breast-feeding is not possible.

Note the similarity between Humanised Trufood and breast milk and the contrast of both with cow's milk.

THERE ARE PLENTIFUL SUPPLIES OF TRUFOOD AVAILABLE

THE INTRAVAGINAL TAMPON IN MENSTRUAL HYGIENE

An important clinical study

Significant facts obtained by the close observation of 25 parous and nonparous women

In view of the increasing use of the intravaginal tampon for the absorption of the menstrual flow, the following important study was undertaken to determine whether or not this method of sanitary control is safe and not prejudicial to health.

Twenty-five women—parous and nonparous—were selected and were under daily institutional observation during two successive catamenial periods. Ranging in age from twenty-one to forty-five, some had previously used tampons, others had not.

The following summary indicates clearly the findings of the study.

1. In not a single instance was there any evidence of local irritation brought about by the use of the tampons.
2. No uterine cramps, suggestive of block of the uterine flow or damming back into the tubes were reported in any case of this series.
3. No bladder irritation was reported.
4. The average number of tampons used in a period was ten.
5. In cases in which a cervical erosion was present, neither the amount of bleeding nor the character of the erosion was altered by the use of the tampons.
6. There was no appreciable difference in the bacterial flora of the vagina and cervix, as determined by smear and culture, before menstruation and after the use of the tampons during the menstrual period.
7. There was no appreciable difference in the pH of the vaginal or cervical secretions before menstruation and after the use of the tampons during the period.
8. Absolute comfort and complete absorption of the flow was obtained by the proper correlation of the size of the tampon with the length and calibre of the vagina.
9. *The evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health.*

MEDICAL INQUIRIES: TAMPAX LTD., 110 JERMYN ST., S.W.1

experimental rupture of the medial ligament of the knee in the cat. Ligamentous recoil always left a gap which could no longer be closed after seven to ten days. Healing occurred except when the rupture was at the upper end of the ligament. These experiments suggested that the ligament should be sutured during the first week, with the least possible damage to its blood supply.

Experiences in Mauritius.—Mr. J. M. Fitton (Mauritius) described the island's peculiarities and the orthopaedic service which had been developed since 1945, when an epidemic of poliomyelitis occurred. Mr. H. J. Seddon (London) referred to the magnitude of Mr. Fitton's task and his modesty. Other Colonial orthopaedic centres had now been established in Malta, Nairobi, and Lagos. It was imperative that the men who built up these centres should find places on their return home.

STAFF COLLEGE FOR HOSPITAL ADMINISTRATORS

KING EDWARD'S HOSPITAL FUND FOR LONDON

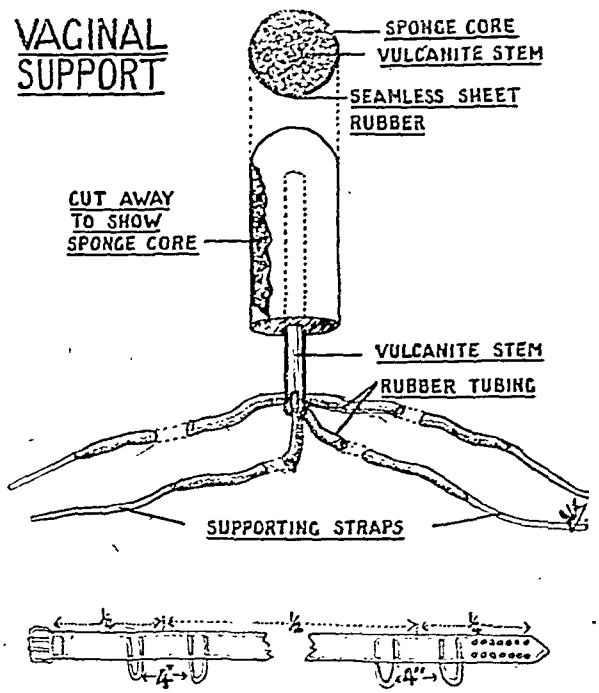
At a meeting of King Edward's Hospital Fund for London held on December 14 at St. James's Palace, H.R.H. the Duke of Gloucester said that the management committee had been giving careful consideration to the ways in which the Fund's resources could best be used. They now sought approval for three main proposals.

It was proposed that a sum of £100.000 should be placed again at the disposal of the Distribution Committee for grants to hospitals. The second proposal involved the allocation of £80,000 to the Convalescent Homes Committee. Thirdly, there were grouped together a number of activities and projects.

Some of these are already well known, for example, the Emergency Bed Service. Others, such as the division of hospital facilities, the staff college for ward sisters, the training school for medical records officers at the Middlesex Hospital, and the projected training centre for hospital caterers at St. Pancras Hospital, were discussed at previous meetings, and have been described in the *Journal*.

The most important new proposal is the establishment of a residential staff college for hospital administrators. On this subject there have been consultations with the Institute of Hospital Administrators, and the Fund has already acquired suitable premises. Mr. Constable, the present house governor of St. George's Hospital, has agreed to resign his hospital appointment and he will become the first head of the new college. Some months must elapse before the college can be opened, but it is already assured of the support of the Ministry of Health.

At the same meeting Sir Wilson Jameson pointed out that in the metropolitan regions there were more than 120 hospital management committees each with a chief administrative officer, and there were, in addition, several hundred senior officers in charge of unit hospitals. Though hospital management called for special inborn qualities of mind and spirit, he thought that much could be done to develop and strengthen these qualities by an enlightened system of training. In some countries training in hospital administration was provided by universities, but in England such provision on any scale was most unlikely, though in the teaching of the subject some of the methods of university instruction might well be used. A college of the kind now proposed—in part residential for students, in part a centre for the exchange of ideas between existing administrators, members of boards and management committees, doctors, nurses, and others connected with hospital work—would do much to raise the standard of hospital administration in this country.



Yugoslavia has made a voluntary contribution of $10.000 to the Supplementary Budget of the World Health Organization for 1950. WHO's regular budget is $7,500.000, but an additional $10.000.000 has been requested from member States in voluntary contributions for the development of health programmes.

Preparations and Appliances

A NEW TYPE OF VAGINAL SUPPORT

Dr. DAVID L. ARNOLD, D.R.C.O.G., writes: In the hope that some measure of relief may be afforded to those who are condemned to a life of semi-invalidism on account of a uterine prolapse for which surgical relief cannot be given, I bring the following appliance to the notice of practitioners.

The first case in which the support was used was one of a thrice-recurrent vaginal vault prolapse. The patient was a married woman aged 62, and was unable to move about without extreme discomfort and pain. She refused to undergo a Le Fort operation, but wished to have some sort of relief from her symptoms. A Napier cup-and-stem pessary was tried, but one week later she still complained of discomfort, and it

was found that the rim of the pessary had ulcerated the vagina over a large area; it was therefore decided to try to design a more comfortable support.

The pessary here illustrated was made and fitted to the patient. It was arranged that its diameter should comfortably fill the vagina, leaving the urinary meatus free of the body of the support, and ¼ in. (1.25 cm.) below its base. It is made of rubber sponge with a sheet-rubber covering and a vulcanite stem, and is supported by a waistband and four straps as used in the cup-and-stem pessary. The patient wears the pessary during the day, inserting it with a little "dettol" cream each morning, and removing it after retiring at night. It is washed and placed in a weak solution of dettol during the night and is ready for use next morning. She has been using the support for two years and continues to be entirely satisfied with it.

Five other cases of procidentia unfit for operation state that the appliance is a success.

It is not suggested that the support should be used in an operable case of prolapse, but it may be of value in any post-menopausal case in which operation is contraindicated. Its advantage over the cup-and-stem pessary is that the pressure area is evenly distributed over the vagina and not confined to one small part.

The appliance is made to order by Messrs. Allen and Hanburys, Ltd.

Reports of Societies

SOME ASPECTS OF UNDERNUTRITION

A meeting of the Section of Experimental Medicine of the Royal Society of Medicine was held on December 13, under the presidency of Professor G. W. PICKERING, when the subject of undernutrition was discussed.

Miss E. M. WIDDOWSON described an experience in 1946 in the British Zone, in the industrial town of Wuppertal, Westphalia. At that time the official German rations provided 1,050 calories a day for the normal consumer. Very few of the population, however, lived as normal consumers. There were many supplementary rations, for one or other of which almost everybody was qualified. The most extraordinary supplement was 30 eggs for the donation of half a litre of blood. Anyone certified as suffering from hunger oedema or as more than 20% underweight also qualified for extra rations in addition to any other extra allowance they might have. Moreover, these supplementary allowances were not the only means of getting extra food; everyone who had a garden cultivated it most diligently.

All the patients certified by their doctors as cases of hunger oedema had to go to a clinic before obtaining their extra rations; it was from these clinics that a group was drawn for more detailed investigation. These people were suffering from calorie deficiency, but not of the most severe type. They looked pale, and it was obvious from their clothes that they had lost a good deal of weight. Oedema was more common in men than in women, particularly in men over 40; it was confined to the legs and generally disappeared after a few days' rest in bed. No signs of vitamin deficiency were seen and there were no complaints of diarrhoea. So far as could be ascertained, there were no deaths in the British Zone which could be attributed solely to undernutrition.

Nineteen men were selected for an unlimited feeding experiment, their ages ranging from 26 to 80 years, and they were given unlimited food for eight weeks. All of them at the beginning showed signs and symptoms of undernutrition; all but two had oedema, and all but one were underweight. They had all been short of food for the previous 18 months. Their first "unlimited" meal was breakfast, at which one of them, aged 80, consumed in margarine, cheese, sugar, and bread the equivalent of 3,170 calories. The men had an unlimited supply of potatoes and other vegetables, tinned meats, dried milk, and cocoa. After a few weeks some were eating less than at first, but others were eating increasing amounts. The average calorie intake during the period was about 6,000 a day, compared with a previous 1,800 or 1,900. These 6,000 calories were obtained from 200 g. of fat, 200 g. of protein, and rather more than 800 g. of carbohydrate. The increase in the amount of food caused no digestive disturbance. The average gain in weight was just over 10 kg. The two octogenarians gained 10.3 and 9.5 kg., respectively. There was no significant change in blood pressure as a result of the feeding. The serum protein rose from 6.4 to 7.1 g. per 100 ml., entirely due to the rise in the globulin fraction.

At the end of the eight weeks, although a few of the men had lost some of their oedema, in others it was worse, and the frequency of the distribution of the various grades of oedema was the same as at the beginning of the experiment. A marked feature was the polyuria, especially at night. The men finally returned to their former rations, which, even when supplemented, amounted to only about one-third of the calories they had been receiving. It was possible to follow the progress of these men during the next two years. At first their weight fell sharply, but with better feeding for the community generally their condition improved considerably.

Professor R. A. MCCANCE spoke briefly on serum cholinesterase. The level of serum cholinesterase, he thought, was a measure of the general metabolic condition or plane of nutrition. For assessing the general nutritional level of a group of 50 or 60 people estimation of the serum cholinesteras level was about as good as any other single test, perhaps better than most. It agreed closely with estimates of the nutritional state from clinical and other tests. But it was good only for group testing. There was considerable variation individually even among normal people, so that it was not much use estimating the serum cholinesterase level of a single person and relating it to the normal average. The other interesting thing about serum cholinesterase was that everything known about it suggested that it had species specificity. Variations with the plane of nutrition, so far as could be discovered, applied only to man.

Birth-weight and Lactation

Dr. R. F. A. DEAN discussed the effect of undernutrition on the size of the baby at birth and on lactation. At Wuppertal the British investigators were fortunate in finding a maternity hospital which had escaped damage during the war, and at which the most meticulous records had been kept for 15 years.

In 1946 a pregnant woman in the British Zone was entitled to food providing about 2,400 calories a day. When she was feeding her baby later she was entitled to 3,500 calories. About 1,200 women in the clinic were interviewed; about half of them said that they got less than 2,400 calories, and 20% said that they got a little over the ration. Nearly all the women wanted more fat. One pint of milk a day was allowed during pregnancy and three pints during lactation. The women were not obviously undernourished and none of them had oedema. They might have been, on a rough estimate, 8% underweight at the beginning of pregnancy. Abnormalities of pregnancy during 1946–7 were not greatly different from those of 1937–8. The average birth-weight in 1937–9 had been about 3,340 g.: in 1945 the average was 3,155. There was a big drop in this respect in the first quarter of 1945, and a further drop in the second quarter, but towards the end of that year there was some recovery. The average daily milk yield of the mother at about the fifth to the ninth day in 1937 was about 320 g.: in 1945 it was 240 g.

It seemed, then, that during the time of the acute food shortage in Germany the children were smaller at birth, and that the mothers had more difficulty in establishing lactation. It was difficult to account adequately for these findings. Some diets which were analysed provided 2,500 calories and contained about 25 g. of animal protein in 75 g. of total protein. It might be that the diet of the women did not contain enough animal protein or that in one way or another it did not provide a good mixture of amino-acids. The psychological upset to which these women had been subjected had, of course, to be considered.

It was possible to follow the growth of 300 children born in 1946 during about six months in 1947–8. The children who were small at birth were nearly always brought up to the average, sometimes quite rapidly, as a result of good feeding. It seemed unlikely that the German children, who now had what food they needed, would show any signs of the hard times during which they were born.

EPIDEMIOLOGICAL RESEARCH ON VIRUS DISEASES

At a meeting of the Devon and Exeter Medico-Chirurgical Society on December 1 Dr. F. O. MACCALLUM spoke on the part played by the general practitioner in epidemiological research on virus diseases.

Virus diseases, Dr. MacCallum said, were coming out of the laboratory and into the field. By taking accurate notes of even a few cases the general practitioner could add to the sum of knowledge in this direction, as had already been done by Dr. Pickles, of Wensleydale. Incubation periods could be verified by noting single and only possible contacts. Material for the diagnosis of virus diseases was readily obtainable by the general practitioner. Material was wanted for labo[illegible] investigation in cases of suspected influenza. [illegible]

questions to be answered. Where did influenza go in the summer? Where did an influenza epidemic start? Vaccines prepared and given in advance might confer immunity to influenza, but it must be confessed that they were often ineffective owing to a change of strain in the virus.

Cases of atypical pneumonia, characterized by acute onset, intense headache, malaise, depression, hacking cough, and absence of fever or other physical signs were probably due to virus infections. One of these infections—so-called Q fever, due to *Rickettsia burneti*—appeared, at any rate in a proportion of cases, to be milk-borne. The incubation period was 14-25 days, and rashes were rare. The rickettsia could be excreted symptomlessly by cows, sheep, and goats for as long as three months, and had been found, though rarely, in cattle ticks and dog ticks.

No serological tests were yet available in this country for differentiating strains of the virus of poliomyelitis. The viruses responsible for a large group of cases labelled "encephalitis" had still to be worked out. The syndrome of lymphocytic meningitis was probably caused by many different viruses. In 80 of 100 cases investigated the virus had not been identified.

Finally Dr. MacCallum pointed out that the distribution of cowpox in this country had not yet been fully mapped, and he asked for scrapings from suspected cowpox lesions.

Correspondence

Colour Plates

SIR,—I am grateful to Professor L. J. Witts for his kind remarks (December 10, p. 1336) about my *Atlas of Bone-marrow Pathology*, but I am disappointed to find that he does not like the colour plates. This is, I am well aware, very much a matter of individual preference, and Professor Witts prefers the lithographic type of reproduction of which Blackfan, Diamond, and Leister's *Atlas of the Blood in Children* is a first-class representative.

There are, however, other views. The *Journal of Pathology and Bacteriology*'s (1948, 60, 648) review of my book said: "In tone, colour, and perfect register these plates do real justice to the skill of the artist, Miss Davison, and are among the very best available in haematological literature. Some of the cells appear small, but they are all drawn to the same scale and their size is actually that which one is accustomed to see with the magnifications usually employed." This last phrase gives the key; the reviewer understands that what I was trying to do was to reproduce the appearances seen down the microscope by those whose job it is to examine bone marrows for diagnostic purposes.

The lithographic illustrations of the *Atlas of the Blood in Children* are beautifully done, but many of the pictures, especially of the more primitive types, show types of cells that are only occasionally seen through the microscope in a blood or marrow film; the plates could not be used for day-to-day help in the laboratory—and were probably not designed for this purpose. Many of the cells in my plates appear not wholly distinct, because that is how they looked. I insisted on a high fidelity of reproduction from the original paintings, and Messrs. Heinemann deliberately rejected the lithographic process because they considered it not good enough to give the results desired. They went to immense trouble to ensure the right "tone, colour, and perfect register." I and Messrs. Heinemann embarked on this production because the many atlases in existence did not, in fact, show actual appearances; most of them showed fine, often very fine, reproductions of paintings of idealized type cells, and the best of the pre-war atlases, that published by Schulten in Germany, was no longer available.

This dilemma, whether to prepare fine reproductions of idealized type cells or whether to endeavour to reproduce actual appearances at the sacrifice of an artificial clarity, has to be faced whenever a colour atlas is contemplated using paintings from which to work. Professor Witts prefers the former; I think the latter of more practical value. Presumably, if colour photomicrography can be sufficiently improved, photographic reproduction will solve the question for us; but that time is not yet.—I am, etc.,

Manchester. M. C. G. ISRAËLS.

Hormones and Rheumatism

SIR,—Dr. Hans Selye's account (November 19, p. 1129) of his most recent work on the adrenal cortical hormones and their inhibiting effect on the development of arthritis makes fascinating reading. I am particularly interested in his interpretation of the results of one experiment.

Fifty rats were divided into five groups, one of which served as controls. The remainder were deprived of food for 24 hours and subjected to various forms of trauma or "stress"—exposure to cold, forced exercise, spinal transection, and injections of formalin—and as a result of these procedures some of the animals were obviously debilitated but others appeared to be in good condition. After subsequent injections of formalin into the paw the controls all developed "formalin arthritis," while the "treated" groups did not. In his interpretation of these results Selye rejects the possibility that the development of lesions was repressed by debility, since some of the animals were obviously in good condition. Instead he suggests—and in your leading article (p. 1159) you agree with him—that the "stress" provoked secretion of ACTH, which in turn stimulated gluco-corticoid production, the last being responsible for the inhibition of arthritis.

For some years I have been intrigued by the effect of debility on the development of lesions in disease. In the case of leprosy[1] and chronic rheumatism[2] I have pointed out that all the agents known to be effective in the suppression of lesions shared a common factor which I referred to as debility but which Selye, perhaps more accurately, describes as stress. I had put down the recession of lesions to the depressing effect of the debility on the reaction of the tissues. While I feel I have no right to dispute Selye's interpretation of this particular experiment, the extensions of this interpretation are sufficiently important to merit discussion.

"Cortisone" release through stress will explain the good results in rheumatism which follow parathyroidectomy and mock parathyroidectomy, fracture of a long bone, hysterectomy, or any major surgical operation. It will explain the effects of gold and atophan poisoning. But what of the success of local measures? Selye's rats injected with formalin between the shoulder blades failed to develop arthritis in the paws. I had believed that such measures as acupuncture, application of Corrigan's button, osteotomy, surgical manipulation, and local injections of distilled water, lactic acid, bee venom, and so on acted locally and produced local effects. While they were generally believed to raise the resistance, I choose to believe that they lowered it by depressing tissue reaction. If these effects are indeed achieved through release of cortisone generally, why should not an injection of lactic acid, say, into the hip cure arthritis in the knee, and why should not manipulation of the elbow improve movements in the ankle? I have discussed this question of local debility following trauma in the paper on rheumatism referred to above. I am convinced that local trauma or interference can operate locally to suppress the development of lesions without the intervention of cortisone.

In discussing the effects of debilitating agents in rheumatism I referred to the reputed efficacy of toxic doses of vitamin D. Here one would now say was a "stress" reaction with cure by cortisone effect. Will cortisone cure lupus, which yields even more spectacularly to vitamin D in toxic doses? And was the previous cure of lupus by Finsen-lamp treatment due to the depressing effect of local trauma or general release of cortisone? Dermatologists, so far as I know, treated all the lesions. Again, I had believed that the cure of general paralysis by malaria could be attributed to the effect of the general debility on the development of anatomical lesions in the brain. I also thought that the local trauma occasioned by the use of convulsants or leucotomy was the agent which repressed the exaggerated behavioural reaction of schizophrenia. Now it

appears that the alarm reaction of malaria or convulsant therapy could release cortisone, which is the final curative agent. But why then are not malaria and leucotomy interchangeable as therapeutic agents?

One more consideration. The effect of stress factors in preventing the development of lesions is beautifully illustrated in the epidemiology of poliomyelitis and in experimental studies of the infection in monkeys. There is the time-honoured observation that the disease attacks only the healthiest children in the community; the incidence is heavy in country districts and light in the towns; heavy in the suburbs and light in the slums; heavy in the well-cared-for children of countries with low infantile mortality and negligible in undernourished tropical children; higher in American whites than negroes; higher in officers than in men; higher in the autumn, when food and vitamins are more plentiful, than in the spring, the season of scarcity, of pellagra and rickets. Experimentally various forms of trauma and malnutrition lower the incidence of disease or give complete protection. Local trauma to the nose and throat region by application of caustics—including, incidentally, formalin—will lower the incidence of the disease. So will deprivation of thiamine or riboflavin. The agents which Selye used to provoke an alarm reaction in rats are all obviously potent in the prevention of poliomyelitis. Selye believes, and you concur in his belief, that these agents finally release cortisone, which prevented or cured formalin arthritis. Do you, Sir, accept the obvious extension of this interpretation of Selye's results? We must wait patiently, I suppose, for increased supplies of cortisone, when practical trial may provide the answers to our questions.—I am, etc.,

Bristol WILLIAM HUGHES.

Failed Forceps

SIR,—In discussing the management of occipito-posterior positions of the foetal head and deep transverse arrest your correspondent, Mr. Derek Freeth (December 3, p. 1298), states, "The correct procedure is, of course, the application of Kielland's forceps and not the displacement of the head above the pelvic brim during further attempts at rotation."

I am fearful that this will make many practitioners who have had to seek further assistance in a case of "failed forceps" feel that if only they possesed a pair of forceps with straight blades all would have been well. While not denying that the use of such an instrument may be attended with excellent results in expert hands, I would draw attention (1) to the words of Alan Brews,[1] "It is not easy to use except for an expert who has made himself well acquainted with it"; (2) to one of the few statistical reports on the use of this instrument and to the fact that it shows a higher foetal mortality than with traditional methods,[2] and (3) Monro Kerr's beautiful description of the technique of manual rotation, where stress is laid on the importance of rotation of the shoulders as well as the head.[3]

The successful management of such cases is dependent on an accurate assessment of the position of the foetal head and the skilled use of the hands and not upon whether one buys a new pair of forceps or not.—I am, etc.,

SIR,—With reference to the letter by Dr. Mabel F. Potter (December 10, p. 1353) I should like to have further particulars. At what stage of labour does she proceed to "spin the occiput"? Is it after full dilatation of the os, before or after rupture of the membranes, and is anaesthesia required? It puzzles me also how pressure with "three fingers on the occiput" could produce flexion of the head. I should have thought it would have extended it further. Further elucidation of these points would be gratefully received.—I am, etc.,

Rhyl, Flints. AUSTEN H. HOLMES.

SIR,—Since two correspondents, Mr. W. P. Hirsch (November 19, p. 1179) and Mr. Bryan Williams (December 10, p. 1353), have stated that there is inadequate consideration of transverse arrest of the head in the standard textbooks in this country, I would respectfully point out that they will find three pages devoted to this particular subject, as well as numerous references in different sections, in *Operative Obstetrics* (Munro Kerr and Chassar Moir, 1949, London).

I would implement the information contained therein by saying that there is no necessity to apply Kielland's forceps in the original manner, but that the "wandering method" with the anterior blade is excellent. This manœuvre removes the danger which has for long been held against the instrument—namely, rupture of the lower uterine segment. There is still another method of putting on the anterior blade when the head is low enough, and that is by direct application. One can easily feel the anterior ear just behind the symphysis pubis in these circumstances, making diagnosis of position easy, and the anterior blade can be directed between the baby's head and the symphysis pubis without disimpaction.

A combination of low spinal analgesia and Kielland's forceps, I believe, is the best method for dealing with transverse arrest of the head, whether deep or otherwise, and for occipito-posterior positions. The operator supplies the extra force required to effect delivery and imitates Nature's mechanism at the same time. I can state, and support with statistics, that foetal mortality is thereby reduced.—I am, etc.,

Oxford. G. GORDON LENNON.

SIR,—I consider that Dr. Mabel F. Potter's letter (December 10, p. 1353) is most misleading. It would appear that confusion exists regarding the definition of persistent occipito-posteriors. I have always understood this to mean direct occipito-posterior (i.e., occipito-sacral). It is established, and I have myself observed, that in many of these cases the head is already well flexed.[1] Hence, if Dr. Potter's interpretation of persistent occipito-posterior is the same as my own, it is difficult to appreciate why flexion—using H. L. Hodge's manœuvre (*Principles and Practice of Obstetrics*, Philadelphia, 1864)—results in anterior rotation.

I can only assume that she refers to occipito-posteriors lying in the oblique position; which leads one to wonder what term she applies to occipito-sacral positions. Furthermore, we know that some 70% of oblique occipito-posteriors rotate spontaneously, so any manœuvre would seem meddlesome unless adequate time has been allowed for this to occur.—I am, etc.

London, N.W.8. R. E. FFRENCH DEVITT.

Operative Treatment of Varicose Veins

SIR,—Mr. R. R. Foote (December 3, p. 1295) quotes me as stating "that elastic-adhesive bandage should not be used in the treatment of varicose ulcer." I advise against the use of an "elastoplast" type of bandage—i.e., one which owes its stickiness to a rubber-zinc spread, because many patients are sensitive to it. This rubber-zinc type of bandage is more adherent and elastic than that spread with the lead paste, and it suits a large number of patients when it is properly put on, but in my hospital clinics its ill-effects are well known and patients fear its application. For this reason I have given up its use. A test for allergy to this elastoplast type of bandage is by the application of a piece of it, the size of a shilling, to the leg: if there is no redness the next day then it can be safely used on that person. I have found that the old-fashioned emplastrum saponis type (diachylon or "lestreflex"), which is also reasonably elastic and adhesive, is almost universally acceptable and equally effective.

As regards Dr. H. M. Hanschell's remarks (p. 1296) on my results, I would say that one pulmonary embolism in a thousand is rather less than the incidence after any clean operation below the diaphragm. With regard to my two cases of deep thrombophlebitis, they affected the leg only and not the thigh.

IN ANALGESIA

1540: "*Take a fatte piece of veale or ellse a fatte capon and boyle it in water or ellse white wyne and strayne it from the fleshe, and sett the saide lycor over the fyre agayn, and putt therto these things folowing, of mallowes ii. unces, of violett leaves, of night shade ana ℥ i. lett them boyle untyll they be very softe and tendre, and powre awaye the licor from them. and putt therto barley water as shall suffise to make it a pulthes*".

(A pulthes to cease payne devised by DR. BUTTS)

Today the physician has, in 'Physeptone,' a specific agent for the relief of pain. 'Physeptone' is more powerful than morphine and does not cause hypnosis or constipation. It may with advantage replace morphine as an analgesic for patients confined to bed. 'Physeptone' is available as 5 mgm compressed products for oral administration (bottles of 25, 100 and 500) and as injection, 10 mgm. per c.c. (ampoules of 1 c.c., in boxes of 12).

'PHYSEPTONE'

dl-2-DIMETHYLAMINO-4:4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

THE ESTABLISHED ANALGESIC

BURROUGHS WELLCOME & CO. (THE WELLCOME FOUNDATION LTD.) LONDON

Relieves pain . . . . elevates mood

'EDRISAL' presents a different and unusually effective form of analgesia. It contains not only two recognized analgesic agents, but also the well-known anti-depressant, 'Benzedrine'. Thus 'Edrisal' relieves pain—*and* dispels the depression which almost always accompanies pain. 'Edrisal' is issued for prescription in bottles of 25 tablets.

ANTACID LUBRICANT

A pleasant and effective combination of *'MILK OF MAGNESIA' with a specially selected grade of MEDICINAL PARAFFIN. Particularly indicated in the treatment of chronic constipation and hyperacidity of the stomach due to disorder of the alimentary tract.

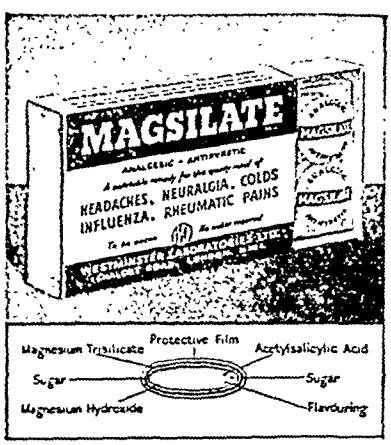
'MIL-PAR' neutralizes excess gastric acidity and checks the development of acid conditions in the food waste. Mixing freely with the fæcal mass it renders it soft and pliable and lubricates the intestinal tract without formation of oily pools and subsequent rectal leakage.

May freely be employed during convalescence from operation or protracted illness, for infants and children, expectant and nursing mothers.

Mil-Par' contains approximately 25% medicinal-paraffin and 6% magnesium hydroxide.

SUPPLIES ARE LIMITED BUT SUFFICIENT STOCKS ARE AVAILABLE FOR DISCRIMINATE PRESCRIPTION

The Chas. H. Phillips Chemical Co. Ltd.



1, WARPLE WAY, LONDON, W.3

Aspirin Therapy brought to Perfection

MAGSILATE

ANALGESIC, ANTIPYRETIC TABLETS

- Aspirin fully protected against deterioration
- Quicker absorption
- More effective action
- No gastric disturbance
- Palatable to eat
- No water required

In cartons of 12 tablets 1/10 (inc. P Tax). Dispensing Packs: 125 tablets, 9/- net and 500 tablets, 35/- net (free of P. Tax).

'ANAHÆMIN'

The *established* treatment for pernicious and other macrocytic anæmias

EVIDENCE is accumulating that the therapeutic action of liver extract in pernicious anæmia depends upon the presence, not only of a primary factor, vitamin B_{12}, but upon the presence also of accessory factors (*J. Clin. Invest.*, 1949, 28, 791).

For most cases of pernicious anæmia, therefore, whether complicated with subacute combined degeneration of the cord or not, Anahæmin is recognised as the preparation for effective treatment; this is acknowledged by the pre-eminent position it has held for more than a decade. Every batch of Anahæmin is clinically tested before issue.

'ANACOBIN'

Solution of PURE crystalline vitamin B_{12}

Occasionally, cases of pernicious anæmia arise which cannot be treated satisfactorily, even with Anahæmin, because of hypersensitivity. For such cases Anacobin is available.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

AnahAnac/B/3a

Both were slight, so that neither heparin nor dicoumarol was used; they responded progressively to compression bandaging. I think that the danger with the method used carries no greater risk from embolism or deep thrombosis than any other clean surgical procedure of similar magnitude. For instance, I recently followed up 300 routine herniae in patients over 50 years old; there were two deaths from pulmonary embolism and one temporarily swollen leg and thigh. Further, these varicose vein results are those of my assistants and myself, the former performing rather more than half.

Dr. Hanschell says, "In an unselected run of over 1,000 patients whose varicose veins are left unabraded and uninjected neither deep thrombophlebitis nor pulmonary embolism is to be expected." I wonder if instead of "is to be expected" he meant "occurred"? None of us expect complications after our clean operations, but . . .—I am, etc.,

New Mechanism of Vitamin Deprivation

SIR,—In his reply to my letter (November 19, p. 1177) Professor A. C. Frazer (December 3, p. 1294) states that his original paper (October 1, p. 731) deals with vitamin deficiency in the sprue syndrome. When this statement, as it seems to do, means "*in the sprue syndrome only*," it is incorrect, since the paper is concerned with the general aspect of vitamin deficiencies. This is obvious from the following items.

(1) The title, "A New Mechanism of Vitamin Deprivation, with Special Reference to the Sprue Syndrome."

(2) From many parts of the text, particularly the introduction, which deals with deficiencies not only of B vitamins but also of vitamins A and D, which are entirely unconnected with the sprue syndrome.

(3) The following passages of the last paragraph of the paper: "This paper is especially concerned with vitamin deficiencies in the sprue syndrome. Special consideration must be given, however, to the possible importance of intestinal bacterial competition in other conditions. A similar competition situation must arise in pernicious anaemia, in which vitamin-B deficiencies are well recognized. . . . The possibility of intestinal bacterial competition along the lines indicated in this paper should be investigated not only in the sprue syndrome but in various other conditions which are thought to be closely associated, such as pernicious anaemia, pellagra, and nutritional megalocytic anaemia (Manson-Bahr, 1940, 1941). The metabolic demands of a varying but essentially non-pathogenic flora may be the key to the problem of the multiple but selective vitamin deficiencies so commonly observed in these conditions."

If Professor Frazer had restricted his discourse to the sprue syndrome alone, as he does in his letter, I would not have commented on it, as I did not do on his former paper[1] on a similar subject but concerned with the sprue syndrome only. I have no personal experience with the sprue problem and I never pretended to deal with it. My comments were based on experience of nicotinamide deficiency as influenced by intestinal bacteria. All of Professor Frazer's replies which rejected my comments as invalid for the sprue syndrome can therefore be dismissed. They have been directed against the claim of having discovered a new mechanism of general vitamin deprivation, which he now withdraws or denies to have had in mind. There are many points in Professor Frazer's letter that would need reply. I limit myself, however, to a few of them.

Professor Frazer is perfectly correct in saying that I do not differentiate between the effects of the administration of natural and of synthetic vitamins. I had always accepted the fundamental pharmacological rule that the action of a chemical compound does not depend on the mode of its origin. Professor Frazer is, however, wrong in saying that I do not differentiate between the effects of different routes of administering the vitamins. A whole paper[2] has been devoted to this problem. I wonder on which experimental evidence Professor Frazer's statement on release or consumption of B vitamins by intestinal *Bact. coli* is based.

I have to apologize for "misquoting" a sentence of Professor Frazer's article by omitting the word "normal" before "human subjects," but this is materially irrelevant, because the investigations quoted were carried out on physically fit persons as well as on pellagrins, and not, as Professor Frazer wrongly states, on deprived subjects or those treated with sulphonamides. From the differences in nicotinamide methochloride elimination before, during, and after administration of succinylsulphathiazole, which changed the composition of the intestinal flora, conclusions were drawn on the importance of these bacteria for the vitamin requirements of the human body.

I fully agree with the statement of the reviewer[3] quoted by Professor Frazer that the full significance of the bacterial synthesis of vitamins by human intestinal bacteria for the vitamin requirements is not yet fully known, but this knowledge can be attained step by step by careful experimental examination only.—I am, etc.,

Vagotomy for Peptic Ulcer

SIR,—In the article by Messrs. I. M. Orr and H. Daintree Johnson on the above subject (December 10, p. 1316) we get the surgeons' point of view. We are now anxious to hear what the physician has to say about it. Meanwhile it would not be amiss to have the opinions of general practitioners, for after all it is they who have to guide the patient in arriving at a decision. The doctor thus asks himself, "If I have a peptic ulcer, would I submit myself to vagotomy?" I should say, "Definitely not." Why undergo the trouble and risk when one can quite well control the secretory activities of the vagus with atropine sulphate in gradually increasing doses? Some disagreeable symptoms are apt to follow vagotomy and it is rather a let-down when, after stopping the secretion of acid, the surgeon has to administer hydrochloric acid to stop the diarrhoea which ensues. He has also found that the best results follow vagotomy plus resection of the ulcer or a gastro-enterostomy.

But I have patients working regularly and apparently cured—some after gastro-enterostomy without vagotomy and others treated solely by medical means—and I maintain that uncomplicated peptic ulcer can be cured by this latter treatment if, and it is a big "if," the patient carries out his instructions faithfully not only for three months or so but for the remainder of his life. For I consider that such ulcers come under the heading of "deficiency diseases," like pernicious anaemia and diabetes. The normal, healthy stomach must form a secretion to protect the mucosa from the digestive action of its own juices. When this is deficient or absent ulceration is prone to develop. It is a permanent condition and therefore ulcers are apt to recur and may be multiple. It is significant that ulcers induced by traumatism in the stomachs of healthy animals heal rapidly.

One can quite understand why uncomplicated ulcers heal after vagotomy, which renders the stomach inert and changes it from an organ of digestion into a mere receptacle, and an uncomfortable one at that, since once the food gets in it is difficult for it to get out again owing to impaired motility. In the medical treatment of peptic ulcer I have learnt that it is imperative to give oils and cream before meals in the endeavour to supply a substitute for the natural protective secretion of the mucosa.—I am, etc.,

Upholland, Lancs. J. THOMSON SHIRLAW.

Aureomycin in the Treatment of Pneumonia

SIR,—Dr. J. G. Scadding's article on "The Management of Acute Pneumonias in Adults" (November 26, p. 1225) prompts me to write of a case I have attended recently.

A male aged 46, weighing 17½ stone (110 kg.), who indulges considerably in alcoholic beverages, came home on November 12, 1949, from watching a football match, feeling shivery and ill. He went to bed and called me in next morning. He was in a very dyspnoeic state with a continuous irritating and non-productive cough, and he complained of severe pain in his left epigastrium, radiating to

the left shoulder-blade and increasing with the slightest movement. He was obviously very ill. His temperature was 103° F. (39.5° C.). His abdomen was very distended. On percussion of the left hemithorax there was dullness of the lower two-thirds, with absence of vibration, the cough revealing crepitations in the upper limit of the dullness. Diagnosis of lobar pneumonia was made. He received 500,000 units of penicillin and 2 g. of sulphadiazine. He had the same amount of penicillin twelve-hourly and 1 g. of sulphadiazine four-hourly until November 22. During these ten days no great change was noticed in his general condition except a slight decrease of the fever. A radiograph taken on November 18, although unsatisfactory because of great technical difficulties in handling a very ill and obese patient, showed a large patch of hepatization of the lower left lung and a small amount of fluid in the costal diaphragmatic margin on the same side.

Penicillin and sulphadiazine were stopped on November 22, and he received 500 mg. of "aureomycin" at 6 p.m. on November 23 orally. This was repeated six-hourly until the total dose was 4 g. The response was dramatic: at 9 p.m. his temperature was 98.4° F. (36.8° C.) and the next day his condition was indeed changed—pain had disappeared, the cough became productive, there was no dyspnoea, and the dullness was less pronounced. His condition continued to improve, and on November 28 his lungs were clinically clear.

Unfortunately the unproductive cough made it impossible to examine the sputum at the beginning, but there was no doubt I was dealing with a case of a penicillin-and-sulphonamide-resistant pneumonia. The immediate response to aureomycin, so easy to administer and without any side-effects, will have to be considered in future in such pneumonias.—I am, etc.,

London, W.1 M. KENIG.

Pathological Fracture Treated by Methyl Testosterone

SIR,—The following case history shows how an ununited pathological fracture of the femur due to metastases from carcinoma of the breast united under the influence of methyl testosterone.

A woman aged 50 was admitted to hospital on March 12, 1948, having sustained a fracture of the middle of the shaft of the left femur after a fall in her home. Five years previously she had had a right radical mastectomy performed for carcinoma of the breast, and this was followed by a course of deep *x*-ray therapy. *X*-ray examination showed a complete transverse fracture of the middle of the shaft of the left femur with areas of rarefaction in the adjacent bone. The pelvis showed multiple areas of increased density due to metastases. *X*-ray examination of the chest showed the lung fields clear.

The fracture remained in perfect position on light traction and subsequently a plaster spica was applied. On September 30, 1948, the fracture was quite ununited clinically and the radiograph showed no callus at all. It was kept in position by strapping extension and a Thomas splint, but by this time the patient's general condition had greatly deteriorated. She was very feeble, was vomiting repeatedly, and required large doses of sedatives daily. On October 25—i.e., after the fracture had been ununited for seven and a half months, the patient being by this time in a state of advanced cachexia—methyl testosterone, 20 mg. three times daily, by mouth was commenced. This was increased to 30 mg. t.d.s. on November 4. She began to improve rapidly, vomiting ceased, and in a few weeks she was able to take full diet. No further sedatives were required and she put on weight. On December 10 her general condition had improved remarkably and she was mentally bright, but large masses were palpable in the abdomen rising from the pelvis. A hard fixed mass could be felt in the pouch of Douglas, and there was a pleural effusion on the right side. The fracture by this time felt firm clinically, and *x*-ray examination showed good callus formation—i.e., after seven weeks on methyl testosterone.

Subsequently she developed gross ascites, bilateral pleural effusions, and oedema of the legs, and she died on January 12, 1949. Necropsy by Dr. Keith Simpson showed advanced carcinomatosis in the chest and abdomen, with massive deposits in both ovaries. There were also deposits in the skull, spine, and pelvis. The left femur was dissected out and found to be soundly united by bone. There was apparently no growth in the shaft of the femur.

Pathological fractures due to metastases from carcinoma of the breast do, of course, frequently unite if properly immobilized. The recalcification of bony metastases from carcinoma of the breast under the influence of methyl testosterone is now well known. The interest of this case lies in the striking (though temporary) improvement in the clinical condition, and the rapid union following methyl testosterone administration of the pathological fracture after non-union for seven and a half months. The temporary effects of methyl testosterone and its lack of influence on the soft tissue growth are noteworthy. Adair's[1] findings are thus confirmed in this case. His observations lead him to recommend intermittent treatment with methyl testosterone, a second course being followed by further improvement.—I am, etc.,

Whipps Cross Hospital, London, E.11. S. G. NARDELL.

The Stability of Society

SIR,—As a mere medical student it is with extreme trepidation that I engage in a joust with Lord Russell. There were, however, one or two points in his erudite, if rather ethereal, Lloyd Roberts Lecture (December 10, p. 1307) to which I would like to draw your attention.

We are told that medical missions in China "do much to diminish the infant death rate; the consequence is that more children die painfully of famine at the age of 5 or 6. The benefit to mankind is very questionable." Medical missions would indeed be gratified if they had reduced the infant death rate by even a fraction of the "much" quoted, and the subsequent aside is hardly relevant to the argument. Is there one law for the Chinese and another for the European? Do we not pride ourselves on the improving record of antenatal and postnatal care? Is such care to be applauded in England and to be condemned in China?

World-wide advocacy of birth control or suitably controlled outbreaks of plague are suggested as means to keep down the world population. Surely a cheaper and more practical method would be for doctors to liquidate their patients instead of to heal them. The chronically sick and infirm, the aged, and the mentally subnormal could be dispatched and thus reduce the number of hungry mouths to be fed. This idea is not so fanciful as it might appear, as we all remember such experiments being carried out in Germany in recent years.

Surely the fundamental error in Lord Russell's thesis is that he tends to regard men *en masse* and not as individuals. He is asking people with hopes and fears and aspirations to submerge their identity in a homogeneous mass. They must forgo the joys and privileges of parenthood because perhaps in fifty years trouble may befall their descendants. I say, God bless those who work among the sick and suffering in China or India or any other country. Let us do all we can to help our fellow men wherever they are in need.—I am, etc.,

London, E.1. JOHN TESTER.

A Sign of Ruptured Ectopic Gestation

SIR,—There are few constant clinical signs in medicine, but I would like to draw attention to one which is, I think, insufficiently recognized. I refer to the loss of consciousness which invariably accompanies the rupture of a Fallopian tube due to an ectopic pregnancy. This is by no means meant as an original observation, for it is mentioned in many places, but it does deserve more prominence, as it may easily be the deciding sign in what may be a difficult diagnosis. I would go further. When one is faced with the usual picture of some six weeks' amenorrhoea, bleeding, and abdominal pain, and if careful questioning elicits a loss of consciousness, however momentary, at the onset of the pain, the diagnosis, in 100% of cases, is a ruptured tube.

This sign does not refer to a tubal abortion, which is different in pathology, symptoms, and prognosis, but I hope I am not labouring the point too much if I again use the word invariable, for I believe this sign to be constant. As such, therefore, it is of the very greatest diagnostic value, and deserves greater prominence than it has hitherto been given.—I am, etc.,

London, W.1. MORTIMER REDDINGTON.

POINTS FROM LETTERS

The Acute Throat

Dr. H. TUDOR EDMUNDS (Slough, Bucks) writes: I am sure many practitioners will feel indebted to Dr. T. Anderson (October 15, p. 860) for his clear exposition on the "Acute Throat" in general practice, but it is surprising he does not mention under the heading of treatment the importance of elimination therapy in throat infections. . . . There is a tendency to-day to over-emphasize the importance of the individual germ and forget the patient. . . . There is an old-fashioned remedy for throat infections which is so simple it is likely to be scorned in these days of complex treatments, but which, if tried, will surprise many practitioners of the younger school. At the onset a brisk purge is given, then calomel, ½ gr. (16 mg.) t.i.d., for three to five days. This dose can be the same for child or adult. The patient is encouraged to take large quantities of fruit juice and water as well as fruit pulp, and a blanket bath is given daily.

Weight Reduction

Dr. P. L. DESHMUKH (Poona) writes: I have been greatly interested in the correspondence on weight-reducing diet for personal reasons as well as in the interest of my patients. The letter of "Apollonian" (July 28, 1945, p. 136) and the subsequent correspondence was a great incentive to me to reduce my own weight. I found his plan very austere. I could maintain myself on it for barely a week doing full work and sport. But then I had to give it up, for the pangs of the plan were enormous for me. There was significant loss of weight for the period, but it soon relapsed to its original level very rapidly. . . . An essential principle in weight reduction, which is often lost sight of, is the stabilization, periodically, of the lower levels of weight reached. It is no use simply going on reducing, for when the restrictions slacken, as they are bound to slacken some time, the weight will start increasing with a vengeance. To prevent this a weight-reducing plan must include a "weight-stabilization" programme. This can be achieved by "re-educating" or "rehabilitating" the metabolism to a lower level or "tune." . . .

Chilblains

Dr. GORDON AMBROSE (Carshalton Beeches, Surrey) writes: Now that we are well into the chilblain season, I think it might be interesting to your readers that I have seen cases of painless swelling of the fingers, and in one case of the toes, following the use of calciferol. I hasten to add that these cases were young women: two were taking halibut-liver-oil capsules, and one was having a course of ultra-violet light at the local hospital for "rheumatism" before and during her course of calciferol. Metabolic disturbances with high doses of vitamin D are well recognized. The effect of painless swelling of the fingers in young women appears out of all proportion to its medical seriousness, and it appears worth while to stop all other sources of vitamin D during a course of calciferol

Angioneurotic Oedema Caused by a Bee-sting

Dr. C. W. A. SEARLE (London, S.W.5) writes: Having read the letter by Surgeon Commander W. R. S. Panckridge and Surgeon Lieutenant C. Q. Henriques (December 10, p. 1354) I am inclined to report a very similar case which occurred in Ahmednagar, India, in March, 1941. I was called to see the wife of the brigade major, who was said to be in great distress, having just been stung by a bee. I saw her within half an hour of having been stung and her condition was exactly similar to that described by the two authors referred to. I also gave a subcutaneous injection of 0.5 ml. of liquor adrenalin, with dramatic effect. Within a few minutes oedema of the glottis had subsided, followed by that of the lids, which was very marked. Within half an hour a clinical cure was effected. She then gave me a history of having been stung by a similar type of bee exactly ten days previously.

Aspirin as a Local Analgesic

Dr. S. HILLMAN (Glasgow) writes: I should like to remind Dr. G. Sclare (December 10, p. 1352) that the insertion of a crushed aspirin into a tooth socket after painful extraction gives real relief. This, in addition to Dr. T. Anderson's reference in his article on the acute throat (October 15, p. 860), adequately illustrates the action of aspirin as a local analgesic.

"Psychosurgery"

Dr. H. THISTLETHWAITE (Sedbergh) writes: I protest vehemently against the use of the word "psychosurgery." Unless you are prepared to equate "mind" (psyche) with "brain" (encephalon) the word can have no meaning. It has no etymological justification. Why could you not use the short, clear, English expression "brain surgery"?

Obituary

SIR CHARLES GORDON-WATSON, K.B.E., C.M.G F.R.C.S.

Sir Charles Gordon-Watson, whose career was one of distinction in military and civil surgery, died at York on December 19 at the age of 75. Before qualifying in 1898 he had enlisted at the age of 20 in the old Volunteers, and afterwards served in the Territorials. In 1899 he went out to the South African war, where he served until 1901 as a civil surgeon in the field force, gaining the medal and three clasps. At No. 1 Field Hospital he was associated with Sir Anthony Bowlby and Dr. Howard Tooth, two seniors from his own school, St. Bartholomew's. In the war of 1914–18 he began his service at the First London General Hospital, and then went to France. There he was in command of the Duchess of Westminster's hospital at Le Touquet. Later, with the rank of colonel, he was consulting surgeon to the Second Army, and afterwards to the British Army in Italy. In the war which began in 1939 he was made consulting surgeon to the British Army at home, and in 1943 he was promoted major-general.

Charles Gordon-Watson [Russell, London]

Charles Gordon-Watson was born in April, 1874, the son of the Rev. Henry George Watson, sometime vicar of St. Leonard's, Buckinghamshire He took the prefix "Gordon" by deed poll in 1920. He was educated at St. Mark's, Windsor, and at St. Bartholomew's Hospital. His service in South Africa followed a period as house-surgeon at his teaching hospital and at the Norfolk and Norwich Hospital. By the time he returned he had chosen general surgery as his career, and he obtained the F.R.C.S. in 1902. He was elected assistant surgeon to St. Bartholomew's in February, 1910, and later became joint lecturer in surgery to the medical school. Other appointments which he held were those of surgeon to St. Mark's Hospital, City Road, to the Metropolitan Hospital, and to St. Andrew's Hospital, Dollis Hill. He remained surgeon to St. Bartholomew's until his retirement under the age limit, when he became consulting surgeon.

In his early days Charles Gordon-Watson was specially interested in orthopaedics, and he collaborated with Howard Marsh in 1910 in the preparation of a new and enlarged edition of *Diseases of the Joints and Spine*, which Marsh had originally published fifteen years earlier. He also contributed articles on this subject to Latham and English's *System of Treatment*. Later he developed an interest in proctology. He was president of the Subsection of Proctology of the Royal Society of Medicine, and often took part in its discussions. He was also the author of the article on diseases of the rectum in Gask and Wilson's *Surgery*. Gordon-Watson served on the council of the Royal College of Surgeons from 1933 to 1940, and in 1937 he was Bradshaw lecturer. He also represented the College on the scientific advisory committee of the Radium Institute and Mount Vernon Hospital, of which committee he was vice-president. In 1931 he was made an Honorary

Fellow of the American College of Surgeons. He was a president of the Aesculapian Society and a member of the British Medical Association, to which he gave some useful assistance at the time—about 1931—when the Association was considering the question of patenting in the medical field. A body with which he was prominently identified for many years was the British Empire Cancer Campaign. He was a member of its executive and chairman of its investigation committee.

Gordon-Watson had an acute and inquiring mind, and never allowed the military cadre within which he worked for so many years to depress his initiative. In 1914 he made what was probably the first observation on trench frost-bite, on the basis of a number of cases admitted to the hospital in France of which he had charge. His military experience made him a strong advocate of the use of "bipp" (a dressing composed of bismuth, iodoform, and petrolatum), which he employed from an early stage of the last war.

To his many fine qualities of head and hand which made him an outstanding surgeon he added a manner of great charm and friendliness which must have been in many trying times a source of encouragement to his colleagues and of reassurance to his patients. At the Bath and Garrick and other London clubs, or on the golf links at Sandwich, he was an admirable companion. During the South African war he formed, with the late Sir Francis Fremantle, the South African civil surgeons dinner, which was held annually for many years. He was made a C.M.G. in 1916, and was knighted in 1919.

We are indebted to Mr. Reginald M. Vick for the following appreciation:

It must sometimes happen that the ordered details of a man's life fail to give an adequate picture of the man himself, and most certainly this is true of someone of the calibre of Gordon-Watson. His vivid personality, his untiring energy, his capacity for friendship, and his earnest desire to help others made him stand out among his fellows. Whatever he undertook he did with abounding enthusiasm. He was very keen on nearly all forms of recreation. As a young man he was a pioneer among motor-cyclists, and on more than one occasion he took part in the annual motor-cycle race from London to Edinburgh and back at a time when these machines were both novel and unreliable. Often I have ridden in the Row with him in the early hours of a summer's day, and I recollect one occasion when he was warned for exceeding the speed limit on his spirited mount He was a most strenuous golfer and an incredibly energetic tennis player. At Bart's, as a student, he played soccer In later years his interest lay in watching rugger, and I know that he always rather regretted that he had never taken part in the titanic struggles for the Inter-hospital Rugger Cup. He was one of the first members of the Bart's staff to drive a motor-car, and to ride with him in those early days of motoring was not without its thrills. In later life he took up horse racing and became a familiar figure on many a race-course.

When wars came, Gordon-Watson was always to the fore He went as a very young man to the South African War In the 1914–18 war he commanded the Duchess of Westminster's Hospital for Officers at Le Touquet, where his surgical skill and powers of organization had full play. He later became consulting surgeon to the Forces in Italy. In the recent war he once more became consulting surgeon to the Forces, which post he held until 1942.

As a teacher he shunned routine methods and taught with originality. As he grew older he spoke with the sure voice of a great experience. In surgery, his outstanding characteristic was courage. There was no operation too extensive for him to refuse to undertake, and he had some wonderful results. In dealing with carcinoma of the colon and rectum, which might be described as his specialty—although he remained a general surgeon to the end of his time—he always believed that it was right to tackle all cases where surgery offered any chance of cure. Needless to say, he had many disappointments, and I have known him to lose heart, but he always recovered rapidly and fought on. He was one of the first surgeons in this country to treat carcinoma of the rectum with radium. As is well known, this method proved a failure in many instances, but he saw to it that it had a full and fair trial. For a long period he treated suitable cases of this disease by the more conservative method of perineal resection, arguing, as was true in those days, that this operation was justifiable because of its lower mortality. Later he used to carry out the abdomino-perineal operation with considerable success. He was always a front-rank fighter in the battle against cancer, and took an active part in organizing research in that field.

One of Gordon-Watson's other lines was traumatic surgery in the days before all fractures automatically passed into the hands of the orthopaedic surgeons. He achieved excellent results with them, largely because of his mechanical turn of mind, which was well known to all who worked with him. He was an advocate of the Balkan beam, and was, I believe, the first surgeon (at Bart's) to affix the beam to a bed. His arrangement was somewhat primitive, but it was the precursor of the complicated fracture beds that we know now.

In his heyday Gordon-Watson had a very large private practice. To assist him at the hospital taught one a great deal, but to work with him in the more difficult surroundings of private practice was a liberal education indeed. He was always keenly interested in students' affairs, and was at one time or another either president or vice-president of many students' clubs. He took his duties seriously and regularly turned up at matches.

I had the privilege of living with him for many years in his house in Harley Street. The household consisted of four bachelors; in those spacious days entertaining on a large scale was the fashion, and it was indeed a gay bachelor establishment. Gordon married late in life, and he and Lady Gordon-Watson were absolutely devoted to one another. It might be said with truth that he never really recovered from the strain of her long and distressing illness, which ended with her death after they had been together for eighteen years. His son Michael now commands the 1st Battalion of the Scots Guards. Gordon-Watson had to undergo a major operation himself towards the end of his life, from which he made a wonderful recovery and came up smiling.

Gordon-Watson made many friends and held them, and there will be many to mourn him. He was always ready with a helping hand towards all those who worked with him. Generation after generation of chief assistants—many of whom are well-known surgeons to-day—house-surgeons, and dressers will bear witness to this splendid spirit in him. One of the most striking things about him was his delightful smile, which truly lit up his face. By his death another famous Bart's man—a great pioneer surgeon and a loyal friend—has passed on his way.

LANCELOT BROMLEY, M.Ch., F.R.C.S.

The sudden and unexpected death of Lancelot Bromley on December 17 at Seaford, Sussex, came as a great shock to his friends, by whom he had always been regarded as the personification of perfect health and physical fitness. The son of Sir John Bromley, he was born in London in

February, 1885. He received his early education at St. Paul's School, where he was captain of the cricket eleven and showed great proficiency as a gymnast. From school he went to Caius College, Cambridge. He played golf for the university and cricket and hockey for his college. He took his B.A. with honours in 1906, and began then his thirty-six years' association with Guy's Hospital. He qualified in 1909, took his F.R.C.S. in 1912, and the M.Ch., Cambridge in 1913.

Bromley made his mark as house-surgeon to Sir Alfred Fripp, and in 1911 he was appointed surgical registrar. He was an excellent teacher, who taught on the patients and not on the textbook description of their diseases. He was warden of the college from 1912 to 1919. In 1914 he married Dora Ridgway Lee, sister of the late Harry Lee, the ophthalmic surgeon of Leeds, who was his contemporary at Guy's Hospital. He was successively demonstrator of anatomy, deputy resident surgical officer, and dean of the medical school. Then in July, 1916, he was appointed assistant surgeon to Guy's. Bromley served in the R.A.M.C. from 1916 to 1918 in Salonika and Italy. On his return he was also appointed surgeon to the Surbiton and Putney Hospitals. It was at these latter hospitals that his ungrudging attendance at all times did so much to develop the scope and usefulness of the surgical service to the patients and their general practitioners. As a result he built up a large practice which continued until his retirement in 1946. In 1942 he resigned from the staff of Guy's in order to continue his work at the Ministry of Pensions Hospital at Stoke Mandeville, where he enjoyed working for ex-Service men—mostly naval ratings. For twenty years he was examiner in surgery at Cambridge, and found much pleasure in these visits to his old university.

His shy, modest, unassuming but helpful character gained for Lancelot Bromley the name of "Daddy," by which he was known to his intimates for over forty years. He had the happy knack of managing his life so well that he was able to combine a busy and successful surgical career with time somehow to satisfy his love of sport, especially golf, racing, yachting, and ski-ing. All these activities were carried out with his family, with whom he spent all his leisure. He was essentially a clinician with a sound knowledge of living pathology and a careful and tender craftsman. He wrote but little, because such time as he may have had for writing was devoted to his wife, children, and three grandsons. His elder son, John, a glider pilot, was killed on D Day near Caen. His daughter is the wife of Dr. R. A. P. Hogbin, a former Guy's rugby captain. His younger son is also a surgeon. As "Daddy" would readily have agreed, he owed his happiness and much of his success in life to the loving and tender care of his wife Dora, to whom all his colleagues and friends will extend sincere sympathy in her great loss.—W. E. T.

W. K. McKINSTRY, M.R.C.S.

Dr. William Kilbourn McKinstry died on December 7 at the early age of 50, after a short illness. The only son of Dr. W. H. McKinstry, now of Brighton and at one time pathologist to the Royal Northern Hospital, he was educated at St. Paul's School and Emmanuel College, Cambridge. McKinstry received his medical education at St. Bartholomew's Hospital and qualified in 1925. After qualification he was R.M.O. at the Westminster Hospital, where he had also been house-surgeon to the ear, nose, and throat and eye departments. He was later a house-physician at the Brompton Hospital.

While at the Westminster Hospital McKinstry had started to take an interest in anaesthetics, and he succeeded, while carrying on a busy general practice in West Kensington, in establishing himself in this specialty. In 1929 he was appointed honorary anaesthetist at the West London Hospital, a post he held until his death. He was also anaesthetist to the National Dental Hospital, and he had served, too, the Victoria Hospital for Children and the Royal Dental Hospital. During the recent war he was anaesthetist to the Royal National Orthopaedic Hospital. It is probable, however, that McKinstry's name will be best remembered in the realm of general practice, for he was in the best sense of the word a "family" doctor Good-looking and with delightful manners, he was soon on friendly terms with new patients, while by his old ones he was considered a family friend, counsellor, and, if necessary, arbitrator. At his memorial service at St. Paul's, Knightsbridge, the writer overheard an elderly man say, "I feel like a ship without an anchor." His friends and colleagues will mourn the untimely death of an always genial and helpful companion.

He leaves a widow, herself a doctor's daughter, and two young daughters. The expressions of sorrow and loss from all his colleagues, patients, and friends may help a little to mitigate for them the tragedy which has overcome a particularly united and happy family.—O. L. C. S.

Mr. Alex. E. Roche, writes: W. K. McKinstry was a friend of very long standing. We went to the same preparatory and public schools, the same university, and the same hospital, and were subsequently close colleagues at another hospital, he being my anaesthetist, and an excellent one at that, and always calm and unruffled. One was completely confident if "Mac" was at the head end. Another, and an astonishing, coincidence is that we married on the same day of the same month of the same year. He was most sane and level headed, and an excellent man from whom to seek advice. He radiated vitality, cheerfulness, and kindliness, and one feels permanently enriched by his friendship. The rapidity and tragedy of his sudden illness leave one stunned, but he was so full of life that he is, and will always remain, vividly present to the memory of those who knew him.

Dr. Redvers Ironside writes: Others may testify to the professional abilities of William Kilbourn McKinstry and his skill as an anaesthetist. May a word or two be added about the loss his friends and colleagues have sustained by his premature death in the fullness of a happy and busy life. He was incapable of an uncharitable thought or deed, utterly unselfish in his work, and with a wonderful quality of imparting cheerfulness and joy to others. His courage and cheerful fortitude in his last illness were an example to those few who were privileged to be with him towards the end. "To live in the hearts of those we leave behind is not to die," and we who mourn his passing will always feel the cheerful, kindly warmth of his personality in remembering him.

J. C. writes: If the men who were boys when I was a boy could sit and drink with me, W. K. McKinstry would be my choice as chairman of that bright band. Years ago we used to meet on Saturday nights at the University of London Union in Malet Street. He was all that a Cambridge man should be: kind, urbane, grave or gay as the occasion demanded. Even then he had acquired that deep wisdom which bids man to be an artist of life: to appreciate folly in season. His death, as it were, snaps the last link in my chain of living reminders of the long days of youth.

Dr. MINA LOUISA DOBBIE died in a nursing-home in Bournemouth on November 23. She was the third daughter of Dr. Robert Dobbie, medical officer of health and general practitioner of Ayr, who died of typhus when she was a girl. She decided to take up medicine early in life, and studied at the London School of Medicine, the Royal Free Hospital, and later in Ireland. After qualifying she was a medical officer at the Crichton Royal Hospital. She became interested in remedial gymnastics and gymnastics for women, and was a pioneer in this field, going to Sweden to study their methods and translating the current Swedish textbook on the subject. She was a close friend and collaborator of the founder of the Chelsea Physical Training School, and was their medical officer for many years. She was also medical officer of the Aske's Haberdashers Girls' School at Acton and New Cross; also of the Maria Grey Training College at Brondesbury. She started general practice in Haverstock Hill, Hampstead, in 1899. She was an active member of the Hampstead Division of the B.M.A. for many years.

Dr. JAMES KIRKWOOD DUNLOP died at Sanquhar on November 24 at the age of 65 He was educated at Kilmarnock Academy, and graduated M.A. in 1905 and M.B., Ch.B. in 1908 at Glasgow University. After a year's assistantship with Dr. Roger in Sanquhar he spent a year as a house-surgeon in the Western Infirmary, Glasgow. He then returned to Sanquhar and continued to practise there until his retirement in June of this year. He was known to everyone in Upper Nithsdale, and when he retired he was presented with an illuminated address as a token of appreciation and respect. He was in every sense the family doctor, and there are few homes in the district where his passing has not meant the loss of a friend. Interested in the community as well as the individual, he served for ten years on the local town council. He was a keen supporter of the British Medical Association, and was chairman of the Dumfries and Galloway Division in 1945–6. While a student he was a keen golfer, and he maintained his interest in the game until ill-health compelled him to stop. For the last few years of his life he suffered from angina, but carried on his practice as he had always done, unselfishly and without counting the cost. Unfortunately, he was able to enjoy only six months' retirement. He is survived by his widow and two sons, to whom his colleagues and friends will extend their sympathy.—J. W.

Dr. THEODORE OGG died at his home in Hampstead, London, on December 5 after a short illness. Born at Fyvie, Aberdeenshire, in 1873, he was educated at Robert Gordon's College, Aberdeen, and at Aberdeen and Edinburgh Universities. As a student he won first prize in obstetrics and gynaecology at the Royal College of Surgeons, Edinburgh, where he later became demonstrator in midwifery. He took the Scottish triple qualification in 1897, and, after practising at Jarrow-on-Tyne and at Rothes, in Morayshire, for a time, he acquired an extensive practice at Huntly, Aberdeenshire. There he was honorary medical officer to the memorial hospital, where he undertook a fair amount of major surgery. He was asked by the Ministry of Pensions after the first world war to form a hospital for the treatment of disabled men from five northern counties. Later, following two years of special postgraduate study at Edinburgh and at Lausanne, where he took an M.D. in 1930, Dr. Ogg came to London. He was clinical assistant to the Soho Hospital for Women, and later physician to the Charterhouse Rheumatism Clinic. He was also medical officer to the Royal Sailors Daughters' School and Home at Hampstead. Dr. Ogg wrote a number of papers on rheumatism and on gynaecological and other subjects. An able diagnostician, he was very conscientious in his work, and endeared himself to his patients by his sympathy and kindness. He is survived by one daughter.

Dr. L. Carlyle Lyon writes: It is with a sense of more than usual regret that I, one of his grateful Aberdeen students of the years 1922–7, read (December 17, p. 1418) of the sudden death on November 29 of Mr. William Anderson, or "Willie," as he was invariably affectionately referred to by us all. As he hurried away after our 1927 Class Reunion Dinner, held in London on March 26 of this year, none of us present could have imagined from his vigorous, though tired, appearance that he would not live to see the New Year. His clinics in the old Aberdeen Royal Infirmary at Woolmanhill, and in the surgical out-patient department across the road, were an example of how medical students should be taught. His kindly handling of patients, putting them at their ease by his spontaneous and friendly use of the native dialect, as well as his consideration for the naïveté of the surgical beginner and his courtesy to the nursing staff, endeared him to all around him. His clinics were therefore always overcrowded, and there was invariably a rush by the more enthusiastic students to be amongst the early arrivals. His lectures on systematic surgery at Marischal College were a model of clarity and lucidity, and a pleasure to attend; while his surgical technique when he was operating was masterly. His place cannot readily be filled, and those of us who worked under him will always be indebted to him. One hopes there will be some fitting memorial erected to William Anderson in his old teaching school.

Dr. C. F. Ross writes: It does not seem long ago since we were giving a tea-party in the lab. for Leslie Humphrey (December 24, p. 1478) on his leaving us to join the R.A.M.C Our chief had concluded a short speech with the words: "I am certain that Dr. Humphrey will make his mark in medicine." How sad it is to think that he was not to be spared to that end—to be cut off so near the beginning. Yet he seemed to have crowded into his short lifetime an amount of experience which some of us may never achieve. Knowing full well the eventual outcome of his illness, his constant solicitude for others shone to the end through the pain and blindness which he bore with such steadfast courage for so many months. Self-pity was entirely alien to his nature. Visits to him in hospital were not so much a consolation to the patient as a privilege to oneself, in making the most of all too fleeting a contact with his mind, too rare to be missed. The triumph of this mind over his body was exemplified in his behaviour, and will be an everlasting inspiration to those who had the honour to witness it. To his wife, whose perfect love and understanding must have given him infinite help in those last dark months, and to his two children, heartfelt sympathy goes out in abundance.

Medico-Legal

ADDICTION TO TRICHLORETHYLENE

At the Birmingham Assizes, on December 12, Mr. Justice Lynskey passed sentence on a man who was said to have killed his mother while under the influence of trichlorethylene, a drug to which he had become addicted.[1] Accepting a plea of not guilty of murder, but guilty of manslaughter, Mr. Justice Lynskey sentenced Peter Edwin Whillier, aged 26, of King's Heath, Birmingham, to five years' imprisonment.

For the prosecution Mr. Arthur Ward, K.C., said it would be difficult to prove intent at the time of the attack and therefore the prosecution was willing to accept this plea. Whillier had been employed at a power station near Birmingham where trichlorethylene was in use. He had got into the habit of soaking his handkerchief in trichlorethylene and inhaling the fumes. He was normally devoted to his mother, but on returning home after working a night shift he attacked her, and she died in hospital from a fractured skull.

Mr. Fearnley Whittingstall, K.C., who defended Whillier, said that he would have been able to call two doctors who would have given evidence that at the time of attack Whillier was in a state of delirium corresponding to that seen occasionally in people coming out of an anaesthetic. He was lashing out wildly without any control whatever.

[1] *Manchester Guardian*, December 13, 1949.

Medical Notes in Parliament

The King's Speech proroguing Parliament on December 16 made no reference to public health or to the passage of the National Health Service (Amendment) Act.

DEBATE ON NUTRITION

On December 15 Mrs. GANLEY opened a debate on nutrition. She commended the Government for continuing rationing, thus securing fair shares for all. She recalled that a leading French specialist had said in 1948 that in ten years England would have a generation of young men and women superior physically and mentally to that of any other European country. He was convinced that the excellent condition of these children was due to their feeding; their diet was perfectly balanced.

Viscountess DAVIDSON said that she had talked recently with two Australian doctors who had come back to this country for the first time since the war. They were deeply distressed at what they saw, particularly the appearance of the ordinary housewife. To produce more in the factories on a diet which only just reached the level of pre-war in quantity, but certainly not in quality, was impossible.

Mr. SOMERVILLE HASTINGS said there was a world shortage of food. Britain must take account of the needs of other countries and not demand more than a fair share of world supplies. In Britain about one-fifth of the people now received less food than before the war, about two-fifths received about the same, but the remaining two-fifths received much more food. He did not forget that there was a high incidence of tuberculosis, but this was probably due to the fact that the disease was more frequently recognized than before the war. There was no clear evidence that the death rate from tuberculosis was increasing. This death rate was the important guide to the nutrition of the people. He was a little unhappy, however, about the consumption of vitamins and fats. The fats the public now obtained were some some 16% below pre-war.

Colonel STODDART-SCOTT remarked that one could not get nourishment out of calories any more than out of a tape machine. What was nourishing was a balanced diet. Over many years this country had developed a diet suitable to its climatic conditions and industrialization. If the country was to get a more nourishing and attractive diet it must get more meat, more animal fats, and more animal proteins. He hoped consideration would be given to the question of food-poisoning. The handling of food was better than in the past and there were more refrigerators, yet the country never had so much food-poisoning as at present. He was sure that if Parliament got rid of rationing, nutrition and the health of the people would improve.

Dr. HADEN GUEST said that within a few years young people would look back on the medical reports of school doctors before the war and on Mr. Seebohm Rowntree's book, *Poverty and Progress*, almost as fairy tales. These conditions might return if food rationing was abolished. The nation was living at a very high standard of nutrition; rationing, price control, and subsidies were necessary to maintain that standard.

Tuberculosis and Nutrition

Mr. WALTER ELLIOT said that in Western Europe in the post-war years there had been a striking recovery in respect of many forms of illness, particularly tuberculosis. The Milroy Lectures, published recently in the *British Medical Journal* (November 12, p. 1065, and November 19, p. 1135), showed a remarkable clearing up of tuberculosis in Europe since 1921. In the years around 1947 the fall in France had been most spectacular. Since 1941 tuberculosis death rates in England and Wales had declined but did not reach the level which had been expected if pre-war trends had been continued. Scotland was the one country which showed no improvement since the end of the war. The trend there actually brought the tuberculosis rate in recent years above the worst period of 1930–1. The death rate from tuberculosis in 1946 in Scotland was 27, in Amsterdam 51, in Copenhagen 44, and in Stockholm 56. In Dundee it had gone up from 82 to 87. If progress was to continue Parliament must see that a more varied diet was available, moving towards the traditional high protein, big meat ration and not depending so much on the large starch ration.

Dr. EDITH SUMMERSKILL said that Mr. Elliot had failed to be objective. She contrasted his speech with his presidential address to the Royal Institute of Public Health and Hygiene published in the *British Medical Journal* (August 6, p. 297). The *British Medical Journal* had headed that address "Tuberculosis: Certain Unexplained Mortality Figures," whereas Mr Elliot had advanced in the present debate an argument trying to prove that the high tuberculosis rates in Scotland could be attributed to the nutritional policy of the Labour Government.

She said that some newspapers had confused averages with specific allocations in discussing rations. If the calorie consumption averaged 3,000 a day and a small child only required a few hundred calories, the heavy workers were consuming something like 4,500 calories. On sugar Dr. Summerskill said there had been a slight increase in consumption but the Government had not the dollars with which to pay for more sugar from Cuba. As for meat, the Ministry of Food had a representative in every meat-producing country who was trying to find available meat supplies. The consumption of milk was 55% greater than before the war and had steadily increased since 1940. A further improvement was expected in 1950. In the present year the Minister of Food had decided to carry out a survey of approximately 2,400 households representative of all economic classes. In this study, made in May, 1949, when milk was unrestricted, the Ministry discovered that the consumption of milk was between 6 pints and 4½ pints per head per week, against 5.4 pints in the highest income groups in the 1930's and 1.1 pints in the lowest income group.

She would like to see more fats available, but a clinical survey had shown no sign of there being a fat deficiency in this country. In 1947 the supply of fats was something like 75% of pre-war, but for the whole of 1949 it was 98% of pre-war. It was good to have margarine fortified with vitamins A and D, and the margarine of to-day was infinitely superior to the yellow grease used years ago. Of flour consumption 19% had been replaced since July, 1949, by the extra fats now available. This was a transfer of 60 calories a day.

The most spectacular change in the public health of the country was the almost complete elimination of rickets. At the beginning of the century one-third of the London children had rickets. Now it was possible to walk down a London street and not see one pair of bandy legs or knock-knees. Cure and prevention of rickets was by means of cod-liver oil, which was now distributed free. The Government was not withholding any of these important nutrients from the poorest income groups. Wise feeding was one of the greatest weapons that preventive medicine could wield, and she looked forward to the day when the Ministry of Food could allocate a balanced diet with a full complement of every nutrient without having to consider the supply question.

The report of the Chief Inspector of Mines for the year 194* has recently been issued (*H.M.S.O.*, price 1s. 3d.). It describes how "beat" diseases account for the largest number of cases of industrial disease in miners at the present time. The incidence of "beat knee" has risen gradually over the past 10 years, and this increase is believed to be due to the growing use of conveyers in the thinner seams. The ideal knee-pad, which will exclude the accumulation of small particles between the pad and the knee, has yet to be designed. Pneumoconiosis continues to be the most important cause of wastage of manpower. The highest incidence is in the South Wales coalfield, but the number of certified cases there has fallen from a peak figure of 5,821 in 1945 to some 3,800 cases in 1947. In the other coalfields of Great Britain there has been an increase from 597 cases in 1945 to some 950 cases in 1947. The report also points out that the number of recorded cases of miners' nystagmus is almost the same to-day as it was ten years ago.

Universities and Colleges

UNIVERSITY OF EDINBURGH

The following medical degrees and diplomas were conferred at a Graduation Ceremonial held on December 16:

M.D.—[3]A. K. Bannister, J. B. Borthwick, D. P. Degenhardt, [1,2]G. W. A. Dick, [4]Rose I. L. Donaldson, [2]J. P. Duguid, [1]D. E. P. Forbes, [1,4]Constance C. Forsyth, [4]I. C. Gilliland, S. H. Graham, [3]A. F. Maccabe, [4]I. A. G. MacQueen, [4]I. C. Monro, M. B. O'Neill, [3]J. B. Wilson.

PH.D.—In the Faculty of Medicine: [1]R. A. Miller, M.D., F.R.C.P.Ed.

M.B., CH.B.—Nancy M. Adams, D. J. M. Allan, T. D. Bleakley, N. T. D. Brewis, J. D. Campbell, I. P. Dunnett, Mary B. Edwards, T. W. G. Fraser, J. H. Greig, C. J. Hardie, D. C. Hudson, Mary E. R. Hughes (née Latimer), Anne E. Jameson, J. D. Litt, Mary B. B. McGregor, A. J. H. MacLennan, J. H. McMillan, D. M. McNab, Margery Matheson (née Dunn), R. D. Merson, P. A. Metcalfe, J. G. Mitchell, R. S. H. Pasqual, D. E. Ryder, I. M. Simpson, Pansy E. Smith, Joyce Stirling, Margaret A. Tait, A. Taylor, Jessie J. F. Tennent, Janet I. Thompson, P. G. W. Weston, T. A. White, Marjorie N. P. Whyte, J. R. Wilson, Sybil M. D. Wood.

D.P.H.—Ewe Hin Ong.

DIPLOMA IN MEDICAL RADIODIAGNOSIS.—E. A. Keith, W. Macleod.

DIPLOMA IN MEDICAL RADIOTHERAPY.—A. Henderson, K. S Mowatt, J. D. Sammon, V. K. Sundaram.

[1]In absentia. [2]Awarded medal for thesis. [3]Highly commended for thesis. [4]Commended for thesis.

UNIVERSITY OF DURHAM

The following medical degrees were conferred in Congregation on December 16:

M.B., B.S.—J. T. Clow, Evelyn C. Cummings, J. M. Finnerty, J. Hayes, Sheila Hedley, A. B. C. Hotobah-During, J. Kirkup, J. McHugh, T. A. O'Sullivan, N. G. Pearson, J. W. Salkeld, W. Shaw, T. Silver, L. B. Strang, E. J. Thomas, D. Veitch, Margaret C. Watkinson, B. H. Webb, D. Webster, R. Williams, *W. D. Baston.

*In absentia.

UNIVERSITY OF BIRMINGHAM

The following appointments have been made: Dr. J. C. Bowie, representative of the University at the Health Congress of the Royal Sanitary Institute, Eastbourne, April, 1950; Mr. S. D. Loxton, Lecturer in Obstetrics and Gynaecology, from December 1, 1949; Dr. E. C. Fox, Lecturer in Operative Dental Surgery, from January 1, 1950.

The title of Honorary Research Fellow in the Department of Physiology has been conferred on Mrs. M. Beznak, M.D.

UNIVERSITY OF LEEDS

At a meeting of the University Court held on December 21 it was decided to confer the honorary degree of D.Sc. on William Norman Pickles, M.D., M.R.C.P., medical officer of health for the Aysgarth Rural District Council, at a Congregation to be held on May 19, 1950.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on December 14, 1949, with Mr. W. Quarry Wood, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows: *N. R. Butcher*; J. C. Campbell, B. S. Dhillon, K. MacD. Douglas, R B. Duncan, R. Fahmy, J. R. Hutchinson, W. S. Johnston, I. Lindsay, R. C. R. Loane, W. C. Lloyd-Smith, W. C. Menzies, J. A. Mitchell, A. L. Morton, K. Prasad, P. L. Rishi, D. E. Robertson, Dorothy E. Rowling, P. N. Simons, I. S. R. Sinclair, B. P. Singh, Z. H. Y. Sobani, A. G. M. Watt.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

Dr. William J. Dieckmann, Director of the Department of Obstetrics and Gynaecology, Chicago Lying-in Hospital, will deliver a lecture on "The Aetiology of Pre-eclampsia—Eclampsia" at the College House (58, Queen Anne Street, London, W.) on Wednesday, January 11, at 5 p.m. Fellows and Members of the College and other medical practitioners interested in the subject are invited to attend the lecture, admission to which is by ticket only, obtainable from the secretary of the College.

Medical News

Crown Representative on G.M.C.

Sir Henry Cohen has been reappointed Crown Representative on the G.M.C. for the term of five years from January 24, 1950. He was first appointed Crown Representative five years ago.

Elastic Adhesive Bandages B.P.C.

The Ministry of Health states that production of one of the two packs of these bandages hitherto in use will be discontinued from January 1, 1950. After that date stocks of the carton "N.H.S." pack may be dispensed where elastic adhesive bandage is ordered on Form E.C.10 while supplies of this pack are being exhausted. The carton pack is being replaced by a pack in tin containers labelled "Elastic Adhesive Bandage B.P.C." Since this pack may be the pack adopted by manufacturers for their branded product, the respective brand name or trade mark of the manufacturer may also appear on the tin. The prices included in the January Drug Tariff for the two widths of this bandage will be the prices for the new tin pack. Whether the carton or the tin pack has been dispensed, these prices will be paid until April 1, after which date the bandage in the tin container only may be dispensed against orders on Form E.C.10. For diachylon base bandages the tin container will be of distinctive colour.

Enjoying Health

How to achieve health and enjoy it is the theme of a pamphlet by Dr. Charles Hill entitled "Health and the Family" (Conservative Political Centre, 1s.). Writing for the lay reader, he discusses the importance to health of a happy home and good conditions of work, and makes some suggestions on such topics as the care of old people and the design of houses. "Men are not changed by legislation," he says, and he gives them plenty of homely advice that will doubtless be more helpful.

Guild of St. Luke

The annual meeting of Catholic doctors of the Guild of St. Luke, SS. Cosmas and Damian was held on December 18 at the Hospital of St. John and St. Elizabeth, London. Dr. W. B. J. Pemberton was re-elected Master of the Guild, Dr. P. Corridan honorary treasurer, and Dr. W. J. O'Donovan honorary secretary. A memorandum setting out the considered opinion of the Guild on some matters raised in the Royal Commission's Report on Population was the chief business discussed at the meeting.

Whooping-cough Research

Dr. Pearl Kendrick, of the Michigan Department of Health, is in London discussing whooping-cough vaccines with British research workers. According to a statement issued by the Medical Research Council, Dr. Kendrick has given valuable help with the investigations into whooping-cough vaccine being carried out in this country. She is discussing on the basis of her wide experience in the U.S.A. present and future trials of whooping-cough vaccine in Britain. Dr. Kendrick is a corresponding member of the Medical Research Council whooping-cough immunization committee, and is here under the auspices of the World Health Organization.

Consultant Psychiatrist to WHO

Dr. Lucien Bovet, chief of the Office Médico-Pédagogique of the Canton de Vaud at Lausanne, has been appointed consultant on juvenile delinquency to the World Health Organization. He will shortly tour Holland, Sweden, Finland, France, England, and the U.S.A.

Treatment of Anthrax, Botulism, and Snake-bite

Arrangements which are to operate from January 1, 1950, are being made for emergency supplies of sera for the treatment of anthrax, botulism, and snake-bite to be kept at the following centres. In each case the centre will maintain a twenty-four-hour service.

Centre	Telephone Number
The Dispensary, Newcastle General Hospital	Newcastle 35211
The Dispensary, Cumberland Infirmary, Carlisle	Carlisle 590
Seacroft Hospital, York Road, Leeds	Leeds 45194
Castle Hill Hospital, Cottingham, York	Cottingham 47372
Nottingham City Hospital, Hucknall Road, Nottingham	Nottingham 42554
Regional Blood Supply Depot, Brookland Avenue, Cambridge: Monday to Friday, 8 a.m.–10 p.m.; Saturday 8 a.m.– 6 p.m.	Cambridge 2536
All other times	Cambridge 87988
North Middlesex Hospital	Tottenham 3071
South London Blood Supply Depot, Benhill Avenue, Sutton	Vigilant 0068
Northampton General Hospital	Northampton 4680
Royal Berkshire Hospital, Reading	Reading 2231
Ham Green Hospital, Bristol	Till 31165
Swilly Isolation Hospital, Plymouth	Plymouth 4311
Canton Infectious Diseases Hospital, Cardiff	Cardiff 960
Dudley Road Hospital, Birmingham	Northern 3801
The Dispensary, Manchester Royal Infirmary	Ardwick 3300
The Fazakerley Isolation Hospital, Liverpool	Aintree 2324

In addition, 10-ml. containers of anthrax antiserum for use *prophylactically* in persons exposed to infection may be obtained during the daytime from the following centres:

Public Health Laboratory, 16-18, Edmund Street, Bradford	Bradford 24314
Public Health Laboratory, 184, High Street, Kingston-upon-Hull	Hull 35371
Bacteriological Department, City Laboratories, 126, Mount Pleasant, Liverpool	Royal 3636
Central Public Health Laboratory, Colindale Avenue, London, N.W.9	Colindale 6041 and 4081
Public Health Laboratory, General Hospital, Westgate Road, Newcastle, 4	Newcastle 34920
Public Health Laboratory, General Hospital, Northampton	Northampton 347
Public Health Laboratory, County Hall, Taunton	Taunton 3451
Public Health Laboratory, Institute of Preventive Medicine, The Parade, Cardiff	Cardiff 8288

COMING EVENTS

Meeting of Registrars

All registrars in the North-west Metropolitan Region are invited to attend a General Meeting at B.M.A. House on Wednesday, January 4, at 4.30 p.m. The objects of the meeting are to elect a permanent committee and also three representatives to the Central Council of the Registrars Group of the B.M.A.

Alcoholism

A joint meeting of the Society for the Study of Addiction and the Section of Psychiatry of the Royal Society of Medicine will be held at 1, Wimpole Street, London, W., on Tuesday, January 10, at 8 p.m., when Dr. Erik Jacobsen, of Copenhagen, will read a paper on "Biochemical Methods in the Treatment of Alcoholism, with Special Reference to Antabuse." A discussion will follow.

Diet in Infancy and Childhood

A course of lectures for postgraduates on "Diet in Infancy and Childhood" will be delivered by members of the staff of the Institute of Child Health and visiting lecturers at the Hospital for Sick Children, Great Ormond Street, London, W.C., on Tuesdays, at 5 p.m., from January 17 to March 21, both dates inclusive. The fee for the course of ten lectures is £3 3s. Applications for tickets of admission (limited in number), accompanied by a remittance, should be sent to the *secretary* of the Institute of Child Health at the hospital.

Society for Endocrinology

The Society for Endocrinology has arranged a lecture on "The Nature of Adrenocorticotropic Hormone (ACTH)" to be given by Dr. C. H. Li (Institute of Experimental Biology, University of California, Berkeley, California) at the Royal Society of Medicine, 1, Wimpole Street, London, W., on Thursday, January 26, at 5 p.m. Admission is free, without ticket.

SOCIETIES AND LECTURES

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—January 3, 5 p.m., "*Animal Diseases Communicable to Man*," by Dr. M. S. Thomson.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—January 3, 5 p.m., "*Tumours of the Kidney*." Erasmus Wilson Demonstration by Mr. C. E. Shattock.

Wednesday

LONDON COUNTY MEDICAL SOCIETY.—At St. Giles's Hospital, Camberwell, S.E., January 4, 3.15 p.m., annual general meeting, followed by an address by Dr. C. D. S. Agassiz.

Thursday

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., January 5, 5 p.m., "*The Homoeopathic Treatment of Common Liver and Gall-bladder Disorders*," by Dr. E. K. Ledermann.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—January 5, 5 p.m., "*Eczema and/or Dermatitis*," by Dr. Brian Russell.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—January 5, 5 p.m., "*Injuries of the Nose and Sinuses*," Otolaryngology Lecture by Mr. Rainsford Mowlem.

ROYAL PHOTOGRAPHIC SOCIETY: MEDICAL GROUP.—At 16, Princes Gate, London, S.W., January 5, 7 p.m., "*Display Methods in Medical Illustration—Graphic and Photographic*," by Miss Sylvia Treadgold (Department of Medical Illustration, Guy's Hospital).

Friday

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—January 6, 5 p.m., "*Tumours of the Testicle*." Erasmus Wilson Demonstration by Mr. C. E. Shattock.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale, London, W.—January 6, 5 p.m., Neurological Demonstration by Dr Redvers Ironside.

Saturday

PHYSIOLOGICAL SOCIETY.—At Guy's Hospital (Physiological Laboratory), London, S.E., January 7, 11 a.m., demonstrations and communications.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Benjamin.—On December 15, 1949, at the London Hospital, E., to Astrid (née Persson) and Hugh Benjamin, M.B., F.R.C.S.Ed., F.R.F.P.S., of Johannesburg, a daughter.

Harrison.—On December 15, 1949, at 10, Millington Road, Cambridge, to Mary (née Marryat), wife of G. Kent Harrison, F.R.C.S., a daughter.

Mellor.—On December 17, 1949, at the Buckingham Nursing Home, Leeds, to Jean Marie (née Walker Wood), wife of Norman Mellor, M.B., Ch.B., a son.

DEATHS

Boyd.—On December 17, 1949, at Blythe Bridge, Stoke-on-Trent, Staffs., Edmund Robert Boyd, M.B., Ch.B.

Bromley.—On December 17, 1949, at Seaford, Sussex, Lancelot Bromley, M.Ch., F.R.C.S.

Buckley.—On December 20, 1949, at Broadhurst, Bury Old Road, Manchester, John Philip Buckley, M.S., F.R.C.S.

Cholmeley.—On December 17, 1949, at the Royal Hospital, Wolverhampton, William Frederick Cholmeley, F.R.C.S., aged 83.

Cope.—On December 17, 1949, at Marylands, Hilltop Crescent, Cosham, Portsmouth, Liderooke Frank Cope, O.B.E., L.S.A., Surgeon Captain R.N., retired.

Egan.—On December 17, 1949, at the London Hospital, E., William Egan, M.R.C.S., L.R.C.P., aged 52.

Gordon-Watson.—On December 19, 1949, at York, Sir Charles Gordon-Watson, K.B.E., C.M.G., F.R.C.S., Major-General, A.M.S.

Hirst.—On December 16, 1949, at Brompton Hospital, London, S.W., Henry Adamson Hirst, M.R.C.S., L.R.C.P., of Spa Grange, St. Helen's Road, Hastings, Sussex, aged 70.

Hutchinson.—On December 20, 1949, at The Cottage, Grammar School Lane, Northallerton, Yorks, Joseph Armstrong Hutchinson, M.D., aged 91.

McClure.—On December 17, 1949, at Edinburgh, Alexander Robert McClure, M.B., Ch.B., of Park House, Wellington, Shropshire, aged 57.

McGregor.—On December 18, 1949, in hospital, Aden, Donald McGregor, M.B., Ch.B., aged 59.

Morris.—On December 19, 1949, in Nairobi, Charles Sculthorpe Morris, M.R.C.S., L.R.C.P., L.D.S., of 77, Albert Hall Mansions, London, S.W., and formerly of 88, Park Street, London, W., aged 74.

Newton.—On December 20, 1949, at 14, Pentland Avenue, Colinton, Edinburgh, William Henry Newton, M.D., D.Sc.

Robertson.—On December 16, 1949, at Hamburg, Hamish Gordon Grant Robertson, M.R.C.S., L.R.C.P., D.P.H., Lieutenant-Colonel, R.A.M.C.

Rorie.—On December 16, 1949, at 41, Albyn Place, Aberdeen, Frank Milne Rorie, M.B., Ch.B., aged 54.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 10. [No. 49

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949 (a)	(b)	(c)	(d)	(e)	1948 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Live births	6,595	1047	849	308	224	7,212	1220	867	303	227
Annual rate per 1,000 persons living			17·0	19·1				17·5	19·0	
Stillbirths	193	27	15			219	24	21		
Rate per 1,000 total births (including stillborn)			17					24		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Typhoid in a Liner

When the liner s.s. *Mooltan* arrived in the Port of London on December 16 three sick members of the crew were removed to hospital for observation. On subsequent days further members of the crew were admitted to hospital, and a diagnosis of typhoid fever has now been confirmed in some of them. On December 22 a total of 11 confirmed cases were under treatment, and 5 further members of the crew were under observation in hospital. The organism is Vi-phage type A Retrospective inquiries suggest that the dates of onset of illness were during the last ten days of the voyage.

One passenger has been admitted to hospital as a suspected case of enteric fever. The names and addresses of passengers and members of the crew who left the vessel have been notified to medical officers of health of the destination to which they were proceeding.

Discussion of Table

In *England and Wales* there were falls in the notifications of whooping-cough 88, measles 58, dysentery 26, and acute poliomyelitis 17, while the only large rise was in the incidence of scarlet fever 100.

A small rise in the incidence of scarlet fever was reported from most areas; the largest increase was London 31. The notifications of measles remained almost constant in most counties; the exceptions were decreases in Durham 212 and Norfolk 83 and an increase in Lancashire of 110, mainly contributed by Liverpool C.B. with a rise from 77 to 145.

A small decrease in the incidence of whooping-cough was recorded in most areas; the only large fall was 47 in Yorkshire West Riding. The only marked change in the notifications of diphtheria was an increase of 8 in Staffordshire.

Two fresh outbreaks of dysentery were reported during the week, one affecting 24 persons in Berkshire, Wokingham R.D., and the other with 18 notifications in Staffordshire, Wolverhampton C.B. Only 2 cases were notified in Gloucestershire and in Cheshire; in the preceding week the notifications were 30 and 16, respectively. The other large returns for dysentery were Lancashire 21 (Preston C.B. 7, Liverpool C.B. 6); London 14 (Poplar 7); Northumberland 11 (Newcastle-upon-Tyne C.B 9). The largest outbreak of food-poisoning was that in which 43 cases were notified in Wiltshire, Salisbury M.B.

In *Scotland* there were decreases in the notifications of acute primary pneumonia 63, scarlet fever 35, whooping-cough 23, and dysentery 21, with increases in the incidence of cerebrospinal fever 12 and diphtheria 8. The rise in the notifications of cerebrospinal fever and diphtheria was contributed by Glasgow. Notifications of dysentery came mainly from Glasgow 23 and Stirling county 15.

In *Eire* there were decreases in the notifications of scarlet fever 34 and whooping-cough 28. Notifications of diarrhoea and enteritis fell by 9 in Dublin C.B., but there was a rise of 14 in the rest of the country.

In *Northern Ireland* there were only small changes in the notifications of infectious diseases. In Belfast C.B. a decline of 31 was reported in the notifications of measles, but there was a rise of 34 in the remainder of the country.

Initial plans for the control of venereal disease in the South-east Asia Regional Organization of WHO are being drafted on the basis of reports furnished by Dr. George M. Leiby, WHO consultant working with the WHO regional office in New Delhi The plan includes a project for the eradication of yaws in Indonesia. Unicef has allocated $700,000 to it. A scheme for controlling syphilis will be combined with it. Dr. Leiby, who is professor of internal medicine and syphilology at the University of California, will also visit Bangkok to discuss plans for V.D. control in Siam. It is believed that adequate V.D. services can be introduced in Ceylon in conjunction with the Mother and Child Welfare Organization there. After completing his tour of Burma and Indonesia, Dr. Leiby will be replaced by Dr. N. Jungalwalla, who will be the permanent consultant in venereal diseases to WHO in South-east Asia.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Control of Dust-borne Infection

Q.—(*a*) *How useful is the oiling of floors and blankets in preventing cross-infection? What oils should be applied, in what quantities, and how often? Can you mention any hospitals using the method now?* (*b*) *What is the best method of aerial disinfection? I take it that the only effective chemical available commercially is sodium hypochlorite?*

A.—(*a*) Dust in a hospital ward consists largely of particles of fabrics from the patients' beds; when these fabrics are contaminated by secretions or discharges the dust arising from them, and the air when dust is formed or disturbed as by bed-making or floor-sweeping, can be shown to contain surprisingly large numbers of pathogenic bacteria. That oiling, by causing such particles to stick together in indispersible masses, much reduces aerial contamination and actually reduces the amount of cross-infection has been fully proved. Papers which should be consulted are those of Thomas and Van den Ende (*Journal*, 1941, 1, 953), Van den Ende and Thomas (*Lancet*, 1941, 2, 755), Thomas (ibid., 1941, 2, 123), Van den Ende, Edward, and Lush (ibid., 1941, 1, 716), and Wright, Cruickshank, and Gunn (*Journal*, 1944, 1, 611). These contain information about methods, which cannot be detailed here, as well as results. The oiling of floors is simple and inexpensive, and requires repetition only at intervals of three or four weeks; the treatment of blankets and garments is much more difficult and expensive and requires skilled laundry co-operation. The only present-day use of both processes of which we have knowledge is in the Burns Unit of the Birmingham Accident Hospital, although it may well be that other hospitals use them. The oiling of floors only has been continued at the L.C.C. North-Western Hospital (where the observations of Wright *et al.* quoted above were made), in the wards of the Facio-Maxillary Unit, Hill End Hospital, St. Albans, and doubtless elsewhere. It should perhaps be pointed out that this method of dealing with infected dust is only one of many precautions, some alternative to it, whereby the risks of cross-infection may be diminished.

(*b*) Most of the information asked for in this question can be found in the memorandum "Studies in Air Hygiene" (*Spec. Rep. Ser. med. Res. Coun., Lond.*, No. 262, 1948), which was the subject of a leading article in the *Journal* for September 17, 1949 (p. 640). The best method of aerial disinfection depends on many circumstances not specified in the question. For temporary use in an emergency such as an air-borne epidemic, and in premises where elaborate installations employing ultra-violet light or glycol vapours are out of the question, it is true that sodium hypochlorite is the best agent available.

Sympathectomy for Intermittent Claudication

Q.—*What are the indications for sympathectomy in intermittent claudication? Is there any means of telling what is the state of the arteries at any time and at any level?*

A.—Recent investigations have shown that sympathectomy is of benefit in the milder degrees of intermittent claudication, where the pain either wears off or remains constant even with continued walking. In such cases a high proportion of patients can be greatly relieved by the operation, or by chemical destruction of the lumbar sympathetic chain by phenol injection, when open operation is contraindicated by the patient's age or general condition. In the more pronounced degrees, when further walking is prevented by the development of severe pain, only about one-third of cases obtain benefit from sympathectomy, and in this group the operation is hardly justifiable. Phenol injection can be tried, provided the patient understands that improvement is by no means certain. If this confers no benefit, tenotomy of the affected muscles should be considered, as this operation can greatly increase the walking distance.

Some indication of the degree of generalized arteriosclerosis can be obtained from estimation of the blood pressure and from palpation of the course and consistency of the brachial and radial arteries, while radiographs of the limbs show the degree of calcification in the arteries. The patency of the arteries at any level can be estimated by palpation of the pulses or by oscillometry, and the presence of other evidence of ischaemia, such as muscle-wasting and pallor of the foot on elevation or exercise. The exact state of the limb arteries can be demonstrated by arteriography, but clinical examination is usually sufficient to assess the extent of the ischaemia.

Subacute Combined Degeneration

Q.—*How should a case of subacute combined degeneration of the cord where the neurological symptoms are predominant be treated? One proprietary liver extract has been used, and discarded because it produced a dark-brown discoloration of the urine with a high specific gravity. Is there any explanation for this, as the urine is otherwise normal? How soon may improvement in the neurological signs and symptoms be expected with adequate dosage?*

A.—Subacute combined degeneration of the cord requires full and intensive treatment, and the doses of the anti-anaemic preparations used should not be reduced even when the blood count has returned to normal. If liver extracts are employed, then doses of 2–4 ml. intramuscularly daily for a fortnight or longer should be followed by similar doses on alternate days, and then two or three times weekly until the condition is much improved. With more concentrated or purified liver extracts, 1–2 ml. should be given at similar intervals. Good responses are obtained to the continued administration of 10 g. of desiccated pig's stomach thrice daily; this should be given in cold water or cold milk after meals and should not be heated. Sometimes in the early stages it is of advantage to combine parenteral liver and oral stomach therapy. Liquid liver extract or proteolysed liver in a dose of 1 oz. (28 ml.) twice daily may also be tried.

Recent investigations have suggested that vitamin B_{12} may be of value in the treatment of this condition, but as yet dosage and long-term effects have not been fully reported. Doses of 40–60 μg. intramuscularly once or twice weekly might be tried. Under no circumstances should folic acid be used, either alone or in combination with any other preparation. Ancillary treatments will include: (*a*) acid. hydrochlor. dil. 30 minims (1.8 ml.) and glycerin. pepsin. 1.5 dr. (5.25 ml.) in a tumblerful of water after each meal if there are any gastrointestinal symptoms; (*b*) supplementary vitamins, especially B complex, and also ascorbic acid (50 mg. three times a day); (*c*) a full normal diet; and (*d*) massage and exercises for the limbs. The response will vary according to the severity of the initial condition, the intensity and persistence of the treatment, and the individual sensitivity of the patient. Improvement should be noticeable in the first few weeks, particularly as the blood count returns to normal, after which it should be progressive although probably slow. Paraesthesiae and some spasticity may persist for a very long time.

A dark-brown urine is noted occasionally after the use of certain very crude preparations of liver, and is probably due to pigmentary matter extracted from the original liver tissue.

Treatment of Coronary Thrombosis

Q.—*What is the most satisfactory modern treatment of coronary thrombosis? Is heparin or dicoumarol of proved value?*

A.—The mortality rate of all cases of acute coronary thrombosis treated with rest alone is in the region of 20%. If an 800-calorie diet is maintained for the first week and a light diet thereafter the mortality rate drops to around 15%. The addition of anticoagulant therapy lowers it another 2½%, and practically abolishes thrombo-embolic complications such as cerebral thrombosis, phlebothrombosis, pulmonary infarction, and massive pulmonary embolism. The slight lowering of the

mortality rate may be fairly attributed to the absence of deaths from massive pulmonary embolism. It is likely, though not yet proved, that the administration of quinidine 3–5 gr. (0.2–0.32 g.) thrice daily for the first month may diminish the number of deaths from ventricular fibrillation. In other words, the combination of a low-calorie diet, anticoagulants, and quinidine may be expected to halve the mortality rate of acute coronary thrombosis. In practice it is usual to limit anticoagulants to those cases in which thrombo-embolic complications are likely. The criteria for employing such therapy include: (*a*) marked fall in blood pressure; (*b*) any evidence of left ventricular failure or congestive heart failure; (*c*) paroxysmal tachycardia or auricular fibrillation; (*d*) electrocardiographic signs indicating gross infarction—for example, monophasic Q waves and persistent elevation of the ST segment in left ventricular surface leads and their equivalents; and (*e*) any direct signs of thrombosis elsewhere. If heparin were easier to give and less expensive, or dicoumarol were less dangerous and required less laborious control, the anticoagulants would probably be given as a routine to all patients; but, as they are not, some selection is usual.

Pruritus During Pregnancy

Q.—*What is the best treatment for pruritus of pregnancy? A patient suffered considerably in her first two pregnancies; she is now two months pregnant and already the irritation has started in the vulva. There are no abnormal physical signs and the urine is free from sugar.*

A.—If the pruritus is limited to the vulva there is nearly always a local cause for it, and, even if there is no glycosuria and no obvious vaginal discharge, vaginal swabs should be repeatedly examined to exclude trichomonas and monilia infection. If all such local causes are excluded, treatment with acid. hydrochlor. dil. 30 minims (1.8 ml.) in a tumbler of water three or four times daily with meals may be tried tentatively. The cause of generalized pruritus associated with pregnancy is unknown, but the nature of the skin lesion rather suggests an allergic basis. Treatment is empirical, and, if antihistamine drugs are ineffectual, stilboestrol, 5 mg. thrice daily by mouth, sometimes seems to help. Calcium gluconate in large doses is also used. Frequent bathing with 1% sodium bicarbonate solution may give temporary relief. When the pruritus is restricted mainly to the abdomen—and it often is—an emollient such as lanoline cream gently rubbed into the skin each day is well worthy of trial.

Hirsutism

Q.—*What investigations are called for in a case of hirsutism? A woman of 28 has a growth of hair on her legs, slight growth on her chin, a tendency to masculine-type pubic hair, and hair round the nipples. Her menstrual history is normal, apart from slight irregularity and amenorrhoea for six months on starting nursing; there is no other evidence of endocrine imbalance. Is it possible to prescribe a depilatory cream which would relieve the hirsutism and, if so, could its use be continued indefinitely without danger?*

A.—The adrenogenital syndrome is usually said to consist of three features—hirsutism, adiposity, and amenorrhoea. Sometimes, instead of adiposity, one gets increased muscular development and strength, and even loss of adipose tissue. In this case the amenorrhoea would appear to be psychological, and should this be so we are probably dealing with a genetically determined hirsutism for which there is no medical or surgical endocrine treatment. In the case of adrenogenital syndrome the usual cause is bilateral hyperplasia of the adrenal cortex, and unilateral adrenalectomy may offer a modicum of relief. An adrenal or ovarian neoplasm is revealed by excessive secretion of 17-ketosteroids in the urine, and by intravenous pyelography or possibly pelvic examination, respectively. Depilatory creams are, in the writer's experience, fundamentally ineffective, and not without danger or severe discomfort. Other physical measures, such as shaving or electrolysis, are on the whole preferable.

NOTES AND COMMENTS

Salicyl-sulphonic Acid Test.—Dr. A. MICHAEL DAVIES (London, N.W.) writes: Under "Any Questions?" (December 3, p. 1306) the use of the salicyl-sulphonic acid test for the detection of "albumin" in urine is discussed and the statement made "that the test is not so delicate as the boiling test. . . ." Some months ago I had occasion to investigate this point and found the converse to be true—i.e., that the sulphosalicylic acid test is twice as sensitive as the boiling test in the detection of protein (*not* "albumin") in urine. A series of dilutions of plasma in urine were made, commencing at 0.5% and running down to 0.005%. The urine was fresh, pooled, and found to be free from protein and other abnormalities. The plasma was human, citrated and pooled, and was found to contain 7.0 g. of total proteins per 100 ml. (biuret method). Each test was performed in triplicate by each of three experienced laboratory technicians and myself, the operator having no prior knowledge of the protein content of the specimen, and the end-point taken to be the faintest detectable (naked eye) opalescence. The results showed close agreement. With 25% sulphosalicylic acid the end-point was reached at 0.04% plasma (a protein content of 2.8 mg. per 100 ml.) and with the boiling test and addition of 2% or 4% acetic acid the end-point was 0.08% plasma, a protein content of 5.6 mg. per 100 ml. The ease and sensitivity of the salicyl-sulphonic acid test make it eminently suitable for surgery or bedside use, and it deserves to be more widely employed. The possibility of false reactions with uric acid and "uroselectan" in no way detracts from its value, and a further point in its favour is the fact that it can be made into a quantitative test by using constant volumes and comparing with a set of standards. I have used it as the routine test for proteinuria in several clinical laboratories with complete success.

The Symptoms of Botulism.—Dr. GERALD LEIGHTON (Ramsey, Isle of Man) writes: In a typical outbreak usually several people are affected. All present the same symptoms within a few hours of each other, varying in severity; all remain for a time unaware of having taken the toxin, and go about as usual. There are no symptoms at all until the patient suddenly complains of dizziness and double vision, when paralysis of the ocular muscles is commencing. This may appear at any time from six hours to about thirty hours: having appeared, the outlook is serious. In a typical case there is no incubation stage with preliminary feverishness; the temperature is slightly subnormal. There is no pain, or only slight pains, no headache, slight vomiting in some cases, none in about half. Then appears the striking sign of more or less complete ptosis. Vision is not impaired. The speech becomes blurred and indistinct: attempts to walk are marked by staggering. There is no pain at this or at any other stage in a typical case. Consciousness remains to the end. As a rule there is obstinate constipation all the time, but no headache nor any rise of temperature. The later symptoms then develop: difficulty in swallowing; the larynx becomes paralysed: power of speech is often completely lost. The mental faculties are fully active and communication is achieved by writing. There is dyspnoea from accumulation of mucus. Lastly the intercostal muscles and diaphragm become paralysed and the circulation fails. Up to this point there is no marked deviation of the pulse from normal.

High-pitched Voice in Adult Male.—Mr. M. VLASTO (Westerham, Kent) writes: I was surprised to read the reply ("Any Questions?" November 26, p. 1246) to the question about high-pitched voice in adult male. The eunuchoid type of voice is heard now and again by laryngologists and speech therapists, who know little or nothing about the "secretions of androgens." In my experience the great majority of such cases have a psychological background and are amenable to therapy along well-established lines. . . .

Correction.—Dr. Terence East's *Failure of the Heart and Circulation* is priced 8s. 6d., not 6s. as stated in our recent review.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY DECEMBER 31 1949

THE SECRETARY REPORTS

CERTIFICATION BY GENERAL PRACTITIONERS

The long-awaited report of the Inter-departmental Committee on Certification, presided over by Mr. Archibald Safford, K.C., is now available, and is summarized elsewhere in the *Supplement*.

In general, the report shows much sympathy with the views expressed in the Association's evidence to the committee. The Association, while recognizing that the issuing of medical certificates where reasonably required is an essential part of a doctor's duty, stressed the importance of ensuring that it does not take precedence over his clinical work. The Safford Committee endorses this view and draws attention to the inroads which unnecessary certification can make on a doctor's opportunities for study and leisure.

In its evidence the Association recommended that the certificates which a doctor is required to give as part of his terms of service should be listed by the Ministry in regulations, and that the list should not be prepared or amended, nor the form of existing certificates altered, without prior consultation and agreement with the profession's representatives. The doctor's obligation, it was suggested, should be limited to giving such certificates as are necessary to make a claim (*a*) for sickness and disablement benefit, (*b*) for essential surgical appliances, and (*c*) for special treatment, under the National Health Service. While the Safford Committee has accepted the first part of this recommendation, it has not accepted the second part in its entirety, regarding such a limitation of the scope of certificates as bearing too hardly on the public. The committee has accepted the proposition that not every certificate required under or for the purpose of an enactment should be included in the approved list.

The General Medical Services Committee was furnished with an advance copy of the Safford Report, together with a statement that the Minister has accepted the recommendations in paragraph 25 that the certificates which a doctor is required to issue free of charge to his patients or their personal representatives under Section 33 (2) (*d*) of the N.H.S. Act should be limited to those certificates which are prescribed under regulations made by the Minister, being certificates reasonably required under or for the purposes of any enactment. The Amending Act contains a clause giving effect to this recommendation, and the G.M.S. Committee has discussed with officers of the Ministry the certificates to be listed in amending regulations shortly to be issued. This consultation with the profession's executive puts into effect the second part of paragraph 25 of the Safford Report, which suggested that borderline cases should be so discussed.

Insurance Certificates

On the subject of the simplification of the forms of certificate, the Association put forward two model forms: (1) combining the First, Intermediate, and Final certificates required by the Ministry of National Insurance, and (2) a simple statement of recommendation (without a certificate of unfitness) for use in connexion with commodities in short supply. The Safford Committee has not recommended the adoption of the first of these two models in the form suggested, but has drafted a model combined certificate which the G.M.S. Committee will shortly examine and discuss with the officers of the departments. On the second of the Association's model forms the Safford Committee does not comment, but one gathers that the committee hopes that the progressive abolition of controls will reduce the number of certificates required for commodities in short supply It is to be hoped that this process will be rapid.

On the question of frequency with which certificates are required to be issued by doctors, the Association recommended (1) that, instead of being required to issue a certificate within twenty-four hours of seeing the patient, the doctor should be given up to seven days; (2) that, in the case of chronic illness, the doctor should be able to issue certificates at three-monthly intervals after the second week. The Safford Committee did not accept the first of these recommendations, but agreed with the second. It describes the present requirement of weekly certificates for the first four weeks of incapacity and four-weekly or eight-weekly certificates thereafter as needlessly exacting, and goes on to say that in acute surgical cases or in cases of certain types of injury it is possible for the doctor to say with assurance, sometimes from the first day of incapacity, that the patient will remain incapable of work for a period exceeding four weeks. Similarly, in cases of permanent incapacity certificates might well be given at intervals considerably in excess of eight weeks. If, as we have reason to believe, these proposals will be accepted, a welcome reduction in the number of certificates will follow.

The Safford Committee has not adopted the Association's recommendation that there should be some relaxation of the requirement to give the diagnosis in certificates, especially those issued for the purposes of receiving some concession or privilege. The committee seems to appreciate the Association's anxiety on this point, and utters a word of advice on the subject of secrecy to those whose job it is to handle medical certificates. The reflection should always be, "Would *I* like other people to know what the doctor has written on *my* certificate?"

Non-medical Certificates

The Association asked that doctors be relieved of the present heavy burden of signing certificates for non-medical purposes —applications for passports, in respect of lost ration books, old-age pensioners' tobacco concessions, etc. There are many classes of the community besides doctors who may witness signatures for these purposes, and it was felt that doctors might be excluded, at any rate in some cases. In oral evidence it was suggested that Government servants at local offices might be included in the categories of persons authorized to attest signatures, and the Safford Committee is in agreement with this suggestion. On the point of excluding the doctor from the list, however, the committee feels that the N.H.S. Act has not altered their position as responsible members of the public.

This commentary on the Safford Report is in no way exhaustive. The report is an important document which requires to be very carefully examined as a whole. Such a scrutiny will be undertaken by the G.M.S. Committee in the near future, and there will follow discussions with the Ministry of Health. For the present, it may fairly be said that the committee's twenty-four sessions have been well spent and that its report will be helpful in clearing the ground for serious discussion on what is, to general practitioners, an important and all-too-substantial part of their daily work.

REPORT ON MEDICAL CERTIFICATES

The Inter-Departmental Committee on Medical Certificates has now issued its report (H.M.S.O., 2s.). The committee was appointed "to consider the medical certificates required under present enactments or regulations or for other administrative purposes and to advise, without excluding the possibility of amending legislation, how far it would be practicable to reduce the number of certificates to be signed by medical practitioners and to improve and simplify the forms of certificates and the rules governing their issue." Its members were Mr. Archibald Safford (chairman), Dr. J. C. Arthur, Miss Florence Hancock, Dr. W. Jope, Mr. E. D. Macgregor, and Mr. R. L. Briggs (secretary).

The committee considers—as medical practitioners will agree—that the primary function of a doctor is therapeutic, and that the time spent in examining patients for the purpose of signing or refusing to sign certificates has undesirable effects on medical practice, to the detriment both of the profession and of the community. "Surgery hours become unduly protracted." The doctor "may well find himself compelled to eliminate visits which he would normally desire to make," or he may have to visit a patient "not in need of medical treatment solely for the purpose of signing a document." "This bears especially hardly on practitioners in rural areas." The report adds that "in the long run the prospect of a harassed life may deter young men from entering the profession."

The committee had some difficulty in defining what is a medical certificate and what is not, for some of the documents before them were medical reports, notifications, attestations, or statements. It points out that a document which a doctor is authorized to sign as an attesting witness is not a certificate; he signs it as a responsible member of the public, not as a doctor. It suggests that Government servants at local offices should be among those authorized to attest such forms.

Form of Certificates

Since any particular control is a question of Government policy, the committee has in most cases confined its suggestions to limiting the occasions when a certificate is asked for rather than advocating its abolition, but has suggested that a number of them be simplified. When new certificates are prepared, advice should be obtained on their form from the medical profession and legal guidance obtained. In particular, the lay-out of similar certificates should be the same, since the same questions asked in different order confuse the doctor who has to answer them.

Discussing the detailed form of the certificates, the committee emphasizes that the doctor's function is to provide evidence of medical facts or inferences, and that it does not extend to a general assurance that the application for which the certificate is used is founded on a true presentation of the other facts of the case. Breaches of this principle are at present common in medical certificates. Again, some questions in certificates require answers on medical facts which the doctor cannot give from his own knowledge, since he has to rely on what the patient says. A typical example given comes from a form used by the Home Office: "Are the periods regular and normal in all respects?" Questions such as this are better framed with the words: "Does the patient (or candidate) state that . . . ?"

One of the most efficacious ways, the committee considers, to reduce the number of medical certificates would be for the Ministry of National Insurance to provide, at the request of insured persons, extracts from certificates of incapacity submitted to that Ministry's local offices in connexion with claims for insurance benefit. These could be used for more general purposes than at present—for example, for presentation to employers.

Some medical certificates play no part in the medical treatment of the patient. The committee recommends a change in the wording of the National Health Service Acts of 1946 and 1947 to provide for the free issue only of "such certificates as may be prescribed, being certificates reasonably required under or for the purposes of any enactment." And whether or not a certificate should be included could be discussed between the medical profession and the Ministry of Health and the Department of Health for Scotland.

B.M.A. Evidence

The committee heard evidence from many Ministries and organizations, including the B.M.A., which submitted evidence in writing and also orally through its representatives, who were Dr. S. Wand, Dr. F. Gray, and Dr. D. P. Stevenson (Deputy Secretary). The Association expressed its strong concern at the increasing divulgence of diagnosis as the result of universal certification for many purposes. While the committee appreciated the B.M.A.'s concern, it pointed out that the National Insurance (Medical Certification) Regulations, 1948, provide that, if disclosing the precise cause of incapacity to the claimant would be prejudicial to his well-being, the certificate may contain a less precise statement. "Further, the general incorporation of a diagnosis enables those administering the payment of benefit to keep a check on the cases for which benefit continues to be claimed without unduly troubling the doctor with inquiries as to the detailed circumstances in which the patient's incapacity has not come to an end."

The Association drew attention to a resolution passed at the A.R.M. (*Supplement*, July 3, 1948, p. 1) that the obligation on a doctor under the N.H.S. Act and its regulations should be limited to such certificates as are necessary to make a claim (*a*) for sickness and disablement benefit as provided by the National Insurance and National Insurance (Industrial Injuries) Acts, (*b*) for essential surgical appliances, and (*c*) for special treatment under the National Health Service. But the committee thought that such limitation would bear too hardly on the public.

Some Recommendations

The report concludes with recommendations on how various certificates should be altered. These include the following:

Ministry of Food—We recommend that the length of validity of a certificate of the need for special rations for active workers should be at the doctor's discretion, and not restricted to one week. We consider that the fairly recent introduction of Form R.G.50a puts an unwarrantable burden on doctors.

Ministry of Health—We consider the demand for a certificate for an ambulance is unjustified except in special circumstances. We do not consider the provision of a certificate to obtain a district nurse or home help is convenient or necessary. We consider that at the most one certificate should be necessary for all purposes to obtain a specially made surgical corset.

Ministry of National Insurance.—We recommend longer intervals between certificates in the case of long-term and permanent incapacity. We recommend that existing arrangements should be extended for the provision of extracts of certificates, for use for more general purposes than at present, and that the assistance of the Organization and Methods Department of the Treasury should be sought.

REMUNERATION OF MEDICAL OFFICERS IN THE ARMED FORCES

After an interval of nine months the Ministry of Defence has agreed to a further meeting on the subject of the Association's proposals for improvements in the pay of medical officers in the armed Forces. The meeting will take place at the beginning of January. It is understood that the Association's proposals have been exhaustively considered by the Ministry and by the Service departments in the intervening period.

CHANGES OF DOCTOR

The Northamptonshire Executive Council has made representations to the Ministry of Health that National Health Service patients should not, unless by mutual agreement, be allowed to change doctors except at quarterly intervals and by giving notice to the council.

Similar representations were recently made by the Ayrshire Executive Council (*Supplement*, December 17, p. 260).

HOSPITAL MANAGEMENT COMMITTEES

An Association of Hospital Management Committees has been formed with the following objects:

(*a*) To provide for the exchange of views and information and the discussion of matters of common interest among hospital management committees.

(*b*) To provide machinery whereby the collective views and suggestions of hospital management committees can be made available to the Ministry of Health or regional hospital boards or, in appropriate cases, to outside bodies (if so agreed at a properly convened meeting of the council of the Association).

Each hospital management committee retains the right to approach or be approached directly by the Minister of Health.

A council has been appointed consisting of two representatives from each region in England and Wales, with the exception of Oxford and East Anglia, where the representatives have not yet been appointed. Special provision has been made to cover questions relating to mental hospitals or mental health. Regional branches will probably be set up.

The following officers have been appointed: *Chairman of the council:* Mr. F. S. Stancliffe (Salford H.M.C.). *Vice-chairman:* Councillor T. McDonald (Caernarvon and Anglesey). *Hon. Treasurer:* Alderman W. J. Garnett (Lancaster Moor). *Hon. Secretary:* Mr. H. B. Shelswell (Secretary, Salford).

GENERAL PRACTITIONERS' REMUNERATION

DEPUTATION TO MINISTRY

A deputation appointed by the General Medical Services Committee met officials of the Ministry of Health on December 22 to discuss the resolutions passed by the committee on December 1 (*Supplement*, December 10, p. 252).

In the terms of the second resolution, an assurance was to be sought from the Ministry of Health "that the central pool will be continuously adjusted so as to maintain in the future —whatever the changes necessitated by the heavy burden of work falling on general practitioners and whatever the increase in the number of doctors—the levels of remuneration recommended in the Spens Report and which were accepted by the Government."

The deputation was headed by Dr. S. Wand, chairman of the G.M.S. Committee, and included Dr. E. A. Gregg, Dr. W. Jope, Dr. H. G. Dain, Dr. F. Gray, and Dr. W. M. Knox.

Heard at Headquarters

Education Grants

Many doctors send their children to independent schools, schools not run by the State—for example, public schools —and may not know that in some circumstances they can obtain financial assistance under the Education Act of 1944. Whether a grant is given is in the discretion of the local education authority. Some education authorities hold scholarship examinations for pupils going on to secondary education. Children who pass these examinations and who then go to independent schools for their secondary education are eligible for grants towards the cost of their education at the independent schools. Grants are usually for tuition only. If need can be proved, an additional grant for board may be made. Doctors who intend to send their children to independent or public schools would be well advised to find out from the local education authority when the scholarship examinations are to be held, since the grants made for successful pupils help substantially towards paying the fees at independent schools. If a child gains an open scholarship to a public school the authority may give the grant without the formality of an examination. The Act provides that pupils are to be educated in accordance with the wishes of their parents so far as is compatible with the provision of efficient instruction and the avoidance of unreasonable public expenditure. An education authority might be willing to make a grant on behalf of a child sent to an independent school if there are no vacancies in the State schools in that area. In other cases there might not be a suitable school within reach of the child's home. Again, if the child had to go to a boarding school because the parents were abroad, the authority might make a grant.

Tyranny of the Headline

Not all the ammunition of public relations, we suppose, will ever blow to pieces the legend that doctors are asking for more money. "Doctors Want More Pay" was the headline in a newspaper the other day. A deputation, we were told, was going to the Ministry "on the claim for an increase of doctors' pay." Actually, as the profession knows, it is not a question of an increase of payment above a level originally agreed, but of arriving at an agreement about the original level, which has been delayed these many months through no fault of the doctors. That, however, cannot conveniently be expressed in a headline, and in these days we are at the mercy of headlines. Headlines often give a wrong impression because they leave out refinements and qualifications which make all the difference. One rather sighs for those earlier days of journalism when there were no snappy headlines an inch deep, and even leading articles appeared without a top dressing.

Many Masters

The discussion in the Public Health Committee the other day on the question of combined appointments—that is to say, the position of public health medical officers who perhaps for nine-elevenths of their time are in the service of the local authority and for the remaining two-elevenths in the service of the regional hospital board—raised the question how far the independence of the medical officer was affected by such an arrangement. That is a moot point, for, as someone sagely remarked, there is something to be said for the view that the more masters a man has the more independence he enjoys.

Questions Answered

Visitors from Abroad

Q.—*What is the procedure for persons requiring free medical attention during restricted visits to England (a) as an urgent matter, (b) for indisposition, or (c) for the provision of aids to vision, etc., all such persons having passports but no National Registration cards? Is it the same for (1) British subjects resident abroad and intending to return thither, and (2) foreign subjects resident abroad and intending to return thither?*

A.—Both British subjects resident abroad and intending to return and foreign subjects resident abroad are entitled to the benefits of the National Health Service during their stay in the United Kingdom. A practitioner giving medical advice and/or treatment to persons in these categories is entitled to claim a temporary-resident fee from his local executive council, whatever the nature or urgency of the illness. Such a patient requiring provision of aids to visions should be given Form O.S.C.1 and referred for examination under the Supplementary Ophthalmic Service. The N.H.S. (Amendment) Act empowers the Minister to make regulations on this subject.

Assistant's Terms of Service

Q.—*Please inform me whether an assistant leaving his principal for a short time to take a higher degree is entitled to any pay during that time, or is the principal justified in either reducing or cancelling his pay pro rata? Is there any provision for study leave?*

A.—The National Health Service Act does not specify the remuneration or terms of service under which assistants are employed. These matters are the subject of mutual agreement between the principal and his assistant and are frequently laid down in a formal assistantship agreement.

REMUNERATION OF OFFICERS OF THE COLONIAL MEDICAL SERVICE

The time has come to give an account of the negotiations which have taken place between the Association and the Colonial Office on the subject of remuneration in the Colonial Medical Service. In drawing up the proposals which were presented to the Colonial Office last February the Colonies and Dependencies Committee attempted to do two things:

(*a*) to arrive at a fair Colonial equivalent of the Spens Recommendations for the remuneration of doctors in the United Kingdom, as implemented in the terms of service for the National Health Service; and

(*b*) to draw up a single uniform scale applicable to all Colonial territories.

The subsequent negotiations have demonstrated that these two objects are to some extent contradictory. The present trend of political development in the Commonwealth is towards self-determination and away from uniformity. One of the chief difficulties which have faced the Association's negotiators has been the wide range of variation throughout the Colonial Empire in such matters as taxation, cost of living, and conditions of life and work. The variation from territory to territory is so marked that a scale of salaries which might be a fair equivalent of Spens in one Colony would be very far from equivalent in another. Consequently the attempt to produce a single uniform scale of figures has been abandoned. Instead, the aim has been to achieve a broad equality of reward. The principle has been to achieve, not the same figures in pounds, shillings, and pence, but the same real return for services rendered in each territory, a return which is comparable with the remuneration of doctors in the National Health Service in the United Kingdom. The adoption of this new and wiser principle has involved modification of the Association's original proposals.

Scope of Negotiations

The discussions which have so far been completed have related only to those areas of the Colonial Empire which recruit a substantial number of doctors from the United Kingdom—namely, Hong Kong, Malaya, Singapore, East Africa, Central Africa, and West Africa. Now that the investigation of this large problem is completed, discussions are about to be undertaken on remuneration in the remaining smaller territories, notably those in the Caribbean area.

It must also be stated that the negotiations up to date have been concerned exclusively with the remuneration of medical officers recruited from the United Kingdom, as their remuneration must necessarily be broadly equivalent to the prospects for doctors in the National Health Service if the Colonial Medical Service is to succeed in securing recruits.

The Association has not overlooked the question of the remuneration of locally recruited officers of the Colonial Medical Service. It is fully appreciated that in some cases their remuneration is the same as that of the officers recruited from the United Kingdom and in some cases is related to it. The Association relies upon its overseas Branches to initiate the negotiation of any modifications which may be considered necessary in the salaries of locally recruited officers, and the overseas Branches can count upon the advice and support of the Association in this task.

Medical Officers and Senior Medical Officers

When it embarked upon its original review of remuneration in the Colonial Medical Service, the Colonies and Dependencies Committee was fully aware that there were advantages and disadvantages of the Colonial medical officer's career for which due allowances must be made in calculating scales of salaries. The principal advantages are: low taxation, generous retirement benefits, cheap housing accommodation, long leave, and study leave. The principal disadvantages are: the difficulty of educating children, separation from home surroundings, high cost of living, arduous climate, relative professional isolation, and the abnormally heavy load of professional responsibility. The committee considered these various opposing factors at great length and came to the conclusion that it was impracticable to attempt to assess their value in terms of money and that the only feasible course was to regard the advantages and disadvantages as cancelling each other out.

The Colonial Office held that this was altogether too sweeping a solution and thought that an attempt ought to be made to evaluate the individual factors financially. One of the chief difficulties in this laborious task has again been the fact that conditions vary so much from territory to territory. Quite apart from the absolute difficulty of estimating the financial value of the advantages and disadvantages of a Colonial career, there is the relative difficulty that the various factors differ in value according to the area concerned.

The Association and the Colonial Office have attempted to arrive as nearly as possible at mean values for the Colonial Empire as a whole. The result of this evaluation, which is described in detail below, shows that the money value of the advantages of a Colonial career substantially outweighs the money value of the disadvantages—a result which of course necessitates revision of the Association's original proposals.

Advantages of Colonial Career

Low Taxation

In all Colonial territories the level of income tax is very much lower than in the United Kingdom. A comparative analysis of the rates prevailing in the United Kingdom with those prevailing in all the territories under discussion was prepared by a firm of accountants. For each territory the accountants were asked to calculate a single difference factor to represent the mean of the difference between United Kingdom taxation and taxation in the territory concerned for salaries of £800, £1,200, £1,600, and £2,000, and for categories of single man, married man, married man with one child, and married man with two children. (The accountants made due allowance for the fact that many more officers are on salaries of £800 or £1,200 a year than on salaries of £1,600 or £2,000.) This complicated task yielded the following principal results:

Area	*Overall Difference Factor*
Hong Kong	21.6%
Malaya and Singapore	20.1%
East and Central Africa	14.5%
Nigeria	17.4%
Gold Coast	20.4%

It is important that the significance of this should be fully understood. In East Africa, for example, the overall difference factor is roughly 14%. This means that a gross income in the United Kingdom must be reduced by 14% to yield the same net income after East African taxation as would be left after taxation in the United Kingdom.

There are other forms of taxation besides income tax, and indirect taxation is in some respects higher in the Colonies than in the U.K. It was found impossible to obtain any complete comparative analysis of all forms of taxation, direct and indirect, central and local, throughout the Empire, but it was considered that the levels of income tax would be a fair index of taxation as a whole.

It was argued by the Association that the great difference in the levels of taxation in Great Britain and the Colonies merely reflected the difference in the benefits received: in other words, the doctors in the Colonies enjoy few of the amenities which are provided by the State in Great Britain. The Colonial Office replied to this argument by pointing out that the two biggest items in the British budget are the costs of defence and the social services, and that defence covers the U.K. and the Colonies equally, while doctors as a class derive relatively little benefit from the social services.

Retirement Benefits

An eminent actuary was asked to analyse the various pension schemes in force in the Colonial Empire, including the widows' and orphans' pension schemes, in comparison with the National Health Service superannuation scheme, which is considered to be fair and reasonable. The actuary presented a detailed report in which he concluded that the Colonial pension schemes were

worth, in general, 14½% of salary more than the National Health Service superannuation scheme. For technical actuarial reasons the actuary advised that in any comparison of salaries the full difference of 14½% should not be allowed, and eventually it was agreed to allow a difference of 12½%.

This means that £100 of salary received by a Colonial medical officer is broadly equivalent, by reason of the retirement benefits to which it leads, to £112 10s. received by a doctor in the National Health Service.

Housing Accommodation

A comparison was made of the expenditure in Britain incurred by doctors upon rent, rates, water, and telephone with the expenditure on these items normally incurred in the Colonies. That portion of these expenditures in Britain which is attributable to the doctor's practice as opposed to his residence was naturally excluded. This is one of the fields where there is great variation between different overseas territories. The comparison showed, however, that in general the expenditure which must be incurred in the Colonies is roughly £60 a year less than that which must be incurred on corresponding items in Great Britain.

It was appreciated that Colonial medical officers are sometimes provided with accommodation which is not of the same standard as housing accommodation in Britain, but against this it was pointed out that their accommodation is usually partially furnished.

Leave

In general Colonial medical officers receive on the average four weeks' more paid leave a year than they would receive if they were working in the National Health Service. This leave is mostly received in the form of long home leave between tours of duty, and it is recuperative—i.e., it is a necessity for a European working in the climatic and other conditions of the Colonies. For this reason no attempt was made to assess this factor in financial terms, but it was set off against the disadvantage of climate (see below).

Study Leave

Colonial medical officers may from time to time receive paid study leave, and their fees for attending courses of instruction and for taking higher examinations may be, and generally are, paid by their employers. This advantage was set off against the disadvantage of relative professional isolation (see below).

Disadvantages of Colonial Career

Education of Children

There is no doubt that the difficulty and expense of educating children is one of the principal obstacles with which the Colonial medical officer has to contend. Once again, conditions vary considerably from territory to territory, but in practically all the education of children presents a problem. A well-known firm of educational agents supplied extensive details of the cost of educating and maintaining boys and girls in middle-class boarding schools in the United Kingdom, and of maintaining them during the holidays. Broadly speaking, the additional cost which falls upon the Colonial medical officer is the cost of maintaining his children in the United Kingdom during the holidays. This was estimated to be £70 a child a year. The fact that a doctor in the United Kingdom does not necessarily have to send his children to a boarding school (although in practice the majority of doctors do) was agreed to be offset by the fact that the children of Colonial medical officers are frequently accommodated with relatives in the holidays, and in any case would involve their parents in some holiday expenditure even if they were not at boarding school in the United Kingdom.

It was agreed to regard the average Colonial medical officer's family as consisting of two children (a number which was subsequently confirmed by the Report of the Royal Commission on Population), and it was agreed to take into account only the eight years of secondary and university education, because primary education is available in a number of territories overseas and not all children proceed to a university. The additional cost of educating two children works out on this basis at £40 a year, when averaged over a 28-year career, which was considered to be approximately the normal length of career in the Colonial Medical Service.

Separation from Home

This is undoubtedly a disadvantage of Colonial life, but it is extremely difficult to estimate it in terms of money. The Colonial Office argued that separation from relatives and from home surroundings was considerably mitigated by the long periods of home leave enjoyed by Colonial medical officers. These do not, however, mitigate the separation of the Colonial medical officer and his wife from their children while they are being educated in the United Kingdom. The problem is how to compute a financial equivalent for this hardship.

It was agreed that this hardship would be largely overcome if each child were able to fly out to its parents each year in the summer holidays, and it was therefore decided that the cost of a student's return air passage might be regarded as the financial equivalent of this hardship. The next difficulty was that the cost of air passages varies considerably for different parts of the world. It was decided to take East Africa as the standard, lying as it does at a middle distance from the United Kingdom. The cost of a student's return air passage to East Africa is approximately £140. This sum for two children during eight years of higher education adds up to a total which when averaged over a career of 28 years, works out at £80 a year.

Cost of Living

This is the most difficult of all the many factors to assess In general, the cost of living in the Colonies is high, but it must be admitted that in some respects the standard of life is correspondingly high. One example will suffice to illustrate this A Colonial medical officer is obliged to employ a staff of servants. These may cost him a considerable sum of money each year, but in return his wife is relieved of most of the domestic duties which are such a burden to the doctor's wife in the United Kingdom. The latter might be delighted to spend £200 a year on servants if she would thereby be relieved of all housework. Who, therefore, is better off—the Colonial medical officer's wife who has to spend much money on servants but is not burdened with housework, or the doctor's wife in the United Kingdom who spends little money on servants but has to do most of her housework herself? This is only one aspect of this complicated subject, but after careful consideration it was decided that the cost-of-living factor is as broad as it is long and might be disregarded.

Climate

This factor is not as important as it once was. It appears that insurance companies nowadays load their premiums only within comparatively restricted latitudes. As already stated above, it was decided to balance this disadvantage against generous leave.

Relative Professional Isolation

By this is meant the fact that Colonial medical officers, while serving abroad, are cut off from scientific and clinical contacts with the remainder of the medical profession in bodies such as the Royal Colleges and the Royal Society of Medicine, and at gatherings such as the Annual Meeting of the British Medical Association. This is a very real loss, but the Colonial Office argued that it was mitigated to some extent by the occasional study leave granted to Colonial medical officers (see above), and, furthermore, the Colonial Office pointed out that relatively few doctors working in the United Kingdom are able to find time for frequent attendance at clinical and scientific meetings. In view of these arguments it was agreed, as stated above, to set this factor off against the advantage of paid study leave.

Extra Professional Responsibility

This is a factor to which the Association attaches great importance. In general the Colonial medical officer does not have at his disposal the same facilities for consultation with specialists or for removal of difficult cases to hospital by

ambulance as exist in the United Kingdom. In many cases he is the only practitioner within call, and he himself has to do whatever is necessary for his patient. There is no doubt that he carries a greater load of responsibility than his counterpart in the United Kingdom. The Colonial Office freely admitted this, but pointed out that this did not apply to medical officers working in the larger centres in the Colonies, and further that the isolation of the medical officer up-country was nowadays diminishing owing to development of roads and air transport.

The Colonial Office also contended that it is the sense of added responsibility and the variation in professional duties which make the Colonial Medical Service attractive to the right type of man. This subject was exhaustively discussed. The Association proposed a figure of £100 a year as compensation for this disadvantage. The Colonial Office was strongly of opinion that this was too high; but eventually, in return for a concession made by the Association in respect of taxation (see below), the Colonial Office was prepared to agree to the general assessment.

A Balance Sheet

Having completed the assessment of the chief advantages and disadvantages, a balance sheet was drawn up as follows:

Advantages	Annual Value	Disadvantages	Annual Value
	£		£
Pension .. .. .. (This is 12½% of £1,300, which was estimated to be roughly the arithmetic mean salary of all Colonial medical officers)	162	Education	40
		Separation	80
		Extra professional responsibility	100
Housing accommodation ..	60		
	£222		£220

It will be seen from this balance sheet that the various factors roughly cancel out, with the exception of the advantage derived from low taxation. No suggestion is made that this analysis of the value of the factors and this balance sheet are anything more than an approximate assessment. Clearly there will be many points in the analysis which are not applicable to a particular territory or to a particular Colonial medical officer; but it represents a square attempt to arrive at a single assessment which can be regarded as fairly and reasonably applicable to the whole Colonial Medical Service, and it yields a conclusion which is probably sound. It indicates that the Association's original proposals, which were based on the assumption that *all* the advantages were counterbalanced by the disadvantages, were too high by the amount of the income-tax factor. This is dealt with below.

The Remaining Factor—Taxation

The only advantage not cancelled out is low taxation. The actuary advised that the Association should not concede the full percentage of the difference factor worked out for each territory by the accountants, because taxation in the United Kingdom is unlikely, for obvious reasons, to rise further, while there is room for taxation in the Colonies to do so. In other words, the difference factor may diminish in the course of the next 25 years or so, and as the Association's intention is to negotiate salary scales which may last a considerable period this possibility must be taken into account.

Against this the Colonial Office argued that in the present uncertain state of human affairs it was impossible to legislate for the future, and the only practicable course was to work on the taxation levels in force at the present day. Eventually, after prolonged negotiation, the Association agreed to concede the whole of the difference factor in respect of taxation in return for agreement by the Colonial Office to the general assessment of the disadvantages, including the figure suggested by the Association in respect of extra professional responsibility (see above).

Application of the Formula

In the case of each territory or group of territories under discussion the total earned by a hypothetical average Colonial medical officer between the ages of 27 and 54 inclusive was compared with the estimated total which will be earned by the hypothetical average general practitioner in the corresponding years in the National Health Service (£47,000) less the appropriate income tax difference factor. For the purpose of this comparison the average Colonial medical officer's career in Africa was assumed to be 13 years as a medical officer and 15 years as a senior medical officer. The average career in Malaya was assumed to be 20 years as medical officer, five years as medical officer Grade B, and three years as medical officer Grade A; and in Hong Kong was assumed to be 28 years as medical officer. These, according to the Colonial Office, were the best estimates that could be made of average careers in the Colonial Medical Service. It must be noted that a medical officer entering the Colonial Medical Service at age 27 would enter the existing salary scale two increments above the minimum in all the territories under discussion except Hong Kong.

These comparisons showed that the existing salary scales (incorporating the latest improvements and excluding cost-of-living allowances) in Hong Kong, Malaya, and Singapore compared favourably with the Spens standards; that the existing salary scales (incorporating the latest improvements and again excluding cost-of-living allowances) in West Africa were broadly equivalent to the Spens standards; but that in East and Central Africa the existing salary scales lagged considerably behind the Spens standards.

This conclusion may come as a surprise to some medical officers in Malaya or in West Africa. An illustration may help to make it clear. It is estimated that the Colonial medical officer in Nigeria can with reasonable efficiency attain a salary of £1,700 a year in the early forties. £1,700 in Nigeria is equivalent to more than £2,000 in the United Kingdom when allowance is made for the difference in taxation. The latter figure compares favourably with the net income (i.e., gross income less practice expenses) of the average general practitioner in the National Health Service at the same age; and £2,000 net corresponds broadly to a gross income of £3,000.

East and Central Africa

As stated above, the existing salary scales in East and Central Africa do not conform to the Spens standards. The Association put forward suggestions to correct this deficiency, and after negotiation the Colonial Office agreed to put certain proposals to the Colonial Governments concerned. These proposals involve lengthening the existing medical officer scale and raising the salaries of senior medical officers. It is regretted that the proposals cannot be published here, because they are under confidential consideration by the East and Central African Governments. It can, however, be stated that they represent a broad equivalence with remuneration in the United Kingdom.

Superscale Posts

The negotiations described above relate only to medical officers and senior medical officers and corresponding officers of the health and laboratory branches. Negotiations with the Colonial Office are also well advanced in respect of clinical specialists and senior medical administrative officers. It is not yet possible to give a full account of these negotiations, but such an account will be published in due course.

Other Matters under Negotiation

A number of other matters have been discussed with the Colonial Office, notably private practice, the burden of non-medical work in the Colonial Medical Service, delay in promotions, recruitment procedure, and remuneration of locally recruited members of the Colonial Medical Service. It is agreeable to report that on all these matters the Colonial Office has shown a realistic and co-operative spirit. Whatever political development may lie ahead for the Colonial Empire, there is no doubt that for many years to come the Colonies will require the advice and assistance of British medicine. The Association is fully alive to the need for a first-class medical

service in the Colonies and is ready to assist in the provision of such a service.

This first report shows that the material terms of service for the average man in the Far East and in West Africa are satisfactory, and that the Colonial Medical Service in those areas offers a favourable career. It is hoped that in due course the same can be said of East and Central Africa.

WHITLEY MACHINERY IN PUBLIC HEALTH

A meeting of the Public Health Committee of the Association was held at B.M.A. House on December 16, Dr. C. Metcalfe Brown presiding.

Nominations for the Whitley Council

It was stated that the nominations for the Medical Functional Council and for its three committees representing consultants and specialists, general practitioners, and public health medical officers, had been formally submitted to the Ministry, and the Ministry had forwarded a draft constitution of the council and its committees which was now being studied. The date for an early meeting of the full Functional Council was under discussion. The medical side of the council would meet on January 3, 1950.

Agreement had been reached that the three branches of the profession should receive equal representation on the council. The consultants and specialists wished to appoint seven members, and accordingly seven had been decided for each of the other two branches. The following had been nominated to represent medical officers in the Public Health Service on the staff side of the council:

Dr. C. Metcalfe Brown, Dr. F. Hall, Dr. R. H. H. Jolly, Dr. Jean M. Mackintosh, Dr. J. A. Stirling, Dr. J. Riddell, and Dr. W. G. Clark.

The Association's representatives on the Public Health Subcommittee were the above together with Dr. Frank Gray (nominated by the Chairman of Council), Dr. Charles Hill, Dr. J. A. Ireland, Dr. G. V. T. McMichael, Dr. Wyndham Parker, and Dr. J. A. Struthers. The committee then proceeded to appoint deputies for each of these, both on the council and on the subcommittee. The hope was expressed that, as a result of the deputation which had been received, discussions under Whitley machinery would begin without further delay.

Combined Appointments

The committee discussed at length the question of whole-time public health medical officers whose duties are partly the responsibility of the local authority and partly that of a regional board. The principles underlying such arrangements had been decided by the committee at its previous meeting. They are that such officers should be in contract with one employing authority only—namely, the one in whose duties they were predominantly engaged—and that their remuneration should be in accordance with the appropriate full-time scale, and with the terms of service for hospital medical staff in the case of an officer in contract with a regional board, with the proviso that there should be no diminution in the officer's present salary. These principles had been placed before the Ministry, which, however, had raised the general question of policy concerning separate contracts with each employing authority. It appeared that the policy of the Association and the policy of the Ministry were at complete variance on this point.

The Secretary (Dr. Charles Hill) outlined to the committee certain points, apart from the immediate issue of remuneration, in respect of which medical officers might be disadvantaged by separate contracts. The most obvious was superannuation; without special provision there might be superannuation loss. There were also the issues of security of tenure and of compensation for loss of emoluments held previously to the advent of the Service.

The committee resolved unanimously that it should be represented to the Ministry that the question of these combined appointments was a matter for discussion within the Whitley machinery. It was also decided to advise members not to sign separate contracts unless they were forced to do so by their local authority, in which case they should add a proviso that this was subject to further discussion and agreement on terms and conditions of service under the Whitley machinery.

Safe Milk

The report of the Joint Committee of the British Medical Association and the National Veterinary Medical Association on the provision of safe milk of high quality was received. The chairman said that this was a first-class report, on which both associations were to be congratulated. It was stated that the report had had extremely good publicity. It was agreed that copies should be sent to all B.M.A. Branches and Divisions, and that a request be made to them to ensure as far as possible that medical representation and advice were available on the county milk and dairies advisory committees. Copies of the report will also be sent to all medical officers of health.

Other Business

Other matters of report to the committee included a statement by Dr. J. M. Gibson concerning the grading in the Leeds and Newcastle areas of medical officers of health who were acting as medical superintendents of isolation hospitals.

It was stated that at a recent meeting with representatives of local authorities final agreement had been reached on the fees payable in respect of certain part-time work undertaken by practitioners for local authorities and had been approved by the Council. It had not yet been possible to settle the date on which the agreement should come into force, but it was likely that joint representations would be made to the Government to have it made effective forthwith.

A meeting had taken place with representatives of Glasgow Corporation on the question of the earlier maximum retiring age which the corporation had fixed for women medical officers. It was now stated that the corporation was in sympathy with the proposal to increase the age from 60 to 65, but was obliged to review the position as affecting all its female employees, which review was now taking place.

The committee considered a proposal to resume the Sir Charles Hastings Lectures in 1950. Eleven such lectures had been given, beginning in 1927 and terminating in 1939. It was the general feeling that the lectures should be resumed. The name of a distinguished medical man as lecturer was suggested, and also the theme, and it was left to the chairman of the committee with the Chairman of Council to further the arrangements.

LONDON ASSOCIATION FOR HOSPITAL SERVICES

THE HOSPITAL SERVICE PLAN

An extraordinary general meeting of the London Association for Hospital Services was held under the chairmanship of Dr. W. Russell Brain at B.M.A. House on December 15, when the Memorandum and Articles of Association were amended to empower the Royal Colleges of Physicians, Surgeons, and Obstetricians and Gynaecologists and the British Medical Association to nominate the medical members of the association, and to make other amendments necessary in the Memorandum and Articles to bring them into conformity with the Companies Act, 1948.

This provident scheme was originally set up by King Edward's Hospital Fund for the London area. Such was the demand for the cover it provides for hospital private-ward and nursing-home treatment that it has been opened to anyone residing within Great Britain and Northern Ireland. Apart from the continually increasing numbers who joined the Hospital Service Plan for this purpose, a large number of medical practitioners have joined the special scheme for doctors; and another special scheme, for boys and girls at boarding schools, has also been popular. This association began to function in 1943, and its funds now amount to just under £50,000.

Correspondence

Advertisements for S.H.M.O.s

SIR,—Not a few of us in the registrar pool must have been cheered by your returning afresh to the onslaught on this fortress of bureaucracy in the columns of the *Supplement* of December 10 (p. 249). A cold blast of disappointment chilled our aspirations when, months ago, you first began to publish advertisements for this unwanted anomaly among specialist posts. We began to wonder if we were abandoned to a fate in which we must play a game like musical chairs, wherein there are always too few places and in which each must scramble for himself—a state in which rivalry ousts co-operation.

I believe the senior hospital officer grade is, as at present constituted, a menace whereby a hard-pressed Ministry could by a stroke of the pen reduce to a mere fraction of the normal total the number of places in the specialist group. Discontent would thus breed rivalry, and rivalry recrimination—greatly to the detriment of clinical effort. For such is human nature, and it is by no means alone a matter of salary, because to say in effect to a man, "We do not want from you clinical output that is at specialist level, but only what is at hospital officer level," is to injure the self-respect of the physician so appointed, to reduce his reputation to that of a sub-standard clinician, to curtail his opportunities of contributing the best that is in him, and almost certainly to debase his standards of actual achievement.

If the need for national economy be the reason for limiting the number of posts carrying specialist rank, surely it is a principle of democracy that the load should be shared by those who are financially the strongest (i.e., all specialists) rather than be laid exclusively upon the shoulders of those who are weaker. For the rest of it, let the principle be upheld that, if a doctor can satisfy the criteria necessary for specialization, then the specialist position offered him should be a real one. He should not be told that he is a holder of a mere third-class ticket and that there is standing room only, while his betters have seats inside the bus. If, on the other hand, he is insufficiently competent or inadequately qualified, surely he is better to hold a post that is really subordinate until he has overcome these limitations.

From whatever standpoint the matter is viewed it becomes apparent that it is in the interests of medical men and of the Health Service alike that the status of senior hospital officer should be reserved for those who for any reason are either unable or unwilling to qualify for consultant rank.—I am, etc.,

D. T. MACLAY.

Leicester.

Voting for Merit Awards

SIR,—It has been brought to my notice that the *Daily Telegraph* (December 17) has published a statement from which some consultants have inferred that the Central Consultants and Specialists Committee of the B.M.A. has advised against co-operation in the distribution of merit awards. May I point out the position?

The Central Committee felt that no body of medical men elected for medico-political purposes should, in their political capacity, pass judgment on their fellows in their professional capacity. The committee, however, saw no objection to the encouragement of hospital staffs, singly or in groups, voting on the names of their members whom they regard as being worthy of special recognition.—I am, etc.,

W. A. BOURNE.

Hove, Sussex.

Unreasonable Demands by Regional Boards

SIR,—I should like to dissociate the Sheffield Regional Hospital Board from the objects of Sir Reginald Watson-Jones's omnibus condemnation in the *Supplement* of December 10 (p. 253). It is the practice in this region to give referees two weeks' notice, which, I think, even Sir Reginald will agree is reasonable.

I wish also to assure him that letters received from referees are actually brought before the Appointment Committee and given serious consideration. So far as Sheffield is concerned, Sir Reginald need therefore have no fear that he will be rushed into precipitate action by scant notice.

It is difficult to understand how a committee composed of reasonable people could draw any special conclusion from the silence of a referee. In one instance we found he was dead.—I am, etc.,

W. A. RAMSAY,
Senior Administrative Medical Officer,
Sheffield Regional Hospital Board.

Branch and Division Meetings to be Held

HYDE DIVISION.—At Jubilee Hall, Dukinfield, Friday, January 6, 8 p.m. to 1 a.m., dance.

LEWISHAM DIVISION.—At Lewisham Hospital, High Street, London, S.E., Friday, January 6, 8.30 p.m., B.M.A. Lecture by Dr Keith Simpson: "Science and Crime Detection."

RICHMOND DIVISION.—At Royal Hospital, Richmond, Friday, January 6, 9 p.m., lecture by Dr. Clare Warren: "On Common Skin Diseases" Illustrated by lantern slides.

Meetings of Branches and Divisions

SWANSEA DIVISION AND SOUTH WALES AND MONMOUTHSHIRE BRANCH

At a joint clinical meeting held at Swansea on December 8 the following cases were shown:—Mr. C. J. Cellan-Jones: A case for diagnosis—a lump behind the larynx Dr. D. Rhys Lewis: Mycosis fungoides, keratosis follicularis (Darier's disease). Mr. Dillwyn Thomas: Three cases of pulmonary resection for bronchiectasis. Mr J. Crowther: A case of double abductor palsy treated by operation. Mr. Gordon Rowley: Three cases of fracture resulting from osteomyelitis treated by penicillin. Dr. T. M. Williams: The use of paravertebral sympathetic block in peripheral vascular disease Mr. R. Derek Richards: Thrombosis of the popliteal artery.

Before the meeting Mr. J. W Tudor Thomas, immediate past president of the Branch, presented the insignia of office to the president and secretary These consisted of a president's jewel with a neckband on which were bars engraved with the names of the eleven past presidents now living, a badge for the secretary, and an ivory gavel for the use of the president.

BELFAST DIVISION

The opening meeting of the session was held in the Whitla Medical Institute, Belfast, on December 15. The chair was taken by the outgoing chairman, Mr. Ian Fraser. He presented to Dr. Douglas Boyd, the retiring honorary secretary, a canteen of cutlery, a gift from the members of the Division He said they all felt that Dr. Boyd had worked tirelessly and fearlessly during many years of difficulty and stress. Dr. Boyd expressed his deep gratitude to the members for their confidence and help during his time in office. Mr. Fraser then installed the new chairman, Dr. J. S. M'Kelvey, and called on him for his inaugural address.

Dr M'Kelvey spoke of "Country General Practice." He pointed out some of the advantages of nearness to sporting facilities and also to the fact that the country practitioner was more on his own than the townsman. Referring to the importance of a clean milk supply, he stressed the opportunity for co-operation between the public health authorities and the farmers in the development of tuberculosis-free herds. Discussing hospitals, he emphasized the importance of specialists and general practitioners having the opportunity to meet and discuss medical problems. He felt that the appointment of general practitioners to clinical posts in the country hospitals would do much more to raise the standard of medicine than any number of refresher courses of two weeks' duration. The interests of both general practitioners and consultants were the same, and it was only by constant recognition of that fact that the Service could become what all would like it to be.

At the conclusion of the meeting all present were entertained to light refreshments by the retiring chairman.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING, 1949: PROCEEDINGS OF SECTIONS (*continued*):
Section of Child Health:
Common feeding difficulties in infancy (R. S. Illingworth and others), 86
Domiciliary care of the premature child (F. I. W. Miller and others), 87
Section of Child Health with Section of Preventive Medicine:
Behaviour difficulties in childhood (Mildred Creak and other contributions), 91
Section of Dermatology:
Tuberculosis and other conditions, 91
Psoriasis (H. W. Barber and others), 173
Use and abuse of chemotherapy (F. F. Hellier and others), 174
See also *Section of Obstetrics and Gynaecology with Section of Dermatology*
Section of Medicine:
Anticoagulants (H. W. Fullerton and others) 162
Cirrhosis of the liver (N. H. Martin and others) 167
Diabetes mellitus (R. D. Lawrence and others), 70
Radioactive substances (Russell Fraser and others), 162
Salicylates in rheumatic fever (G. Watkinson), 167
Streptomycin (Geoffrey Marshall and others), 161
Section of Medicine with Section of Surgery:
Treatment of peptic ulcer (Sir Henry Cohen, A. Hedley Visick, and others), 78
Section of Neurology and Psychiatry:
Intractable pain (J. Purdon Martin, Wyllie McKissock, and others), 83
See also *Section of Surgery with Section of Neurology and Psychiatry*
Section of Obstetrics and Gynaecology:
Breech presentation (R. Newton and others). 71
Functional uterine haemorrhage (V. B. Green-Armytage and others), 168
Section of Obstetrics and Gynaecology with Section of Dermatology:
Pruritus vulvae (T. N. A. Jeffcoate, G. A. Grant Peterkin, and others), 88
Section of Obstetrics and Gynaecology with Section of Radiology:
Radiography and disproportion (J. Chassar Moir and others), 80
Section of Occupational Health:
Future of occupational health (Donald Stewart and others), 84
Tuberculosis and occupation (Alice Stewart and others), 165
Section of Ophthalmology:
Angiomatosis retinae (A. G. Cross), 92
Eye and skin (J. H. Doggart and others). 92
Ophthalmology in Spain and Holland (John Foster), 174
Scleromalacia perforans (H. V. Ingram), 92
Toxoplasmosis (A. B. Nutt), 174
Watery eye (N. P. R. Galloway), 92
Section of Orthopaedics:
Fractures of radius and ulna (E. Mervyn Evans and others), 75
Lesions of thoracic inlet (Lambert Rogers and others), 76
Section of Orthopaedics with Section of Rheumatology:
Arthritis of hip-joint (H. Petty and others), 86
Physical treatment of arthritis (H. F. Turney), 86
Synovial membrane (D. V. Davies and others), 85
Section of Oto-rhino-laryngology:
Nasal allergy (R. R. Simpson and others), 91
Respiratory obstruction in children (G. E. Archer and others), 175
Section of Pathology and Bacteriology:
Care and treatment of laboratory animals (J. Vinter and others), 73
Chemotherapy in malignant disease (E. C. Dodds, A. Haddow, and others), 162
Laboratory diagnosis and prevention of whooping-cough (R. Cruickshank and others), 72
Pathology of hypersensitivity reactions (Hilding Bergstrand and others), 169
Temporal arteritis (C. V. Harrison), 170
Vascular changes in diabetes (Norman Ashton), 170
Section of Pathology and Bacteriology with Section of Tropical Medicine:
Sprue syndrome (A. C. Frazer and others), 80
Section of Preventive Medicine:
Pregnancy and tuberculosis (F. A. H. Simmonds), 92
See also *Section of Child Health with Section of Preventive Medicine*
Section of Radiology:
Radiology of joints (E. Duff Gray and others). 170
Radiotherapy in spondylitis ankylopoietica and osteoarthritis (E. L. Gwendolen Hilton and others). 81
Scope and limitations of radiotherapy (J. S. Fulton, Chester Williams, and others), 73
See also *Section of Obstetrics and Gynaecology with Section of Radiology*

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING, 1949: PROCEEDINGS OF SECTIONS (*continued*):
Section of Radiology with Section of Cardiology:
Angiocardiography (Frances Gardner and others), 89
Section of Rheumatology:
Report on 7th International Congress on Rheumatic Diseases, New York (G. D. Kersley), 166
Rheumatoid arthritis in the young (Bernard Schlesinger and others), 76
See also *Section of Orthopaedics with Section of Rheumatology*
Section of Surgery:
Pain in right iliac fossa (A. Fullerton and others), 171
Prostatic obstruction (H. Hamilton Stewart and others), 74
See also *Section of Medicine with Section of Surgery*
Section of Surgery with Section of Neurology and Psychiatry:
Head injury (G. F. Rowbotham and others). 163
Section of Tropical Medicine:
Loaiasis (G. J. Stefanopoulo and others), 78
Tropical diseases as aftermath of war (T. C. St. C. Morton and others), 77

Housing: New houses, 1222
— Summary of progress, May, 1949, 419
Houston, Sir Thomas, obituary of, 34
HOWARD, S. J.: Poisoning by ferrous sulphate, 1298
HOWAT, R. G.: Lead nipple shields, 931
HOYLE, L.: Treatment of cutaneous anthrax, 875
HOYTE, H. J.: Open sesame, 1180
HUBBLE, D. V.: Miracles of George Fox (Nova et Vetera), 281
HUBINONT, Pierre O.: Iso-immunization by blood-group factors A and B in man, 574 (O)
HUDSON, F. P.: New neonatal syndrome, 871
HUGHES, E. S. R., SMALL, H. A. D., and MACKY, J. W. F.: Congenital pyloric stenosis in binovular twins, 741; correspondence, 1180
HUGHES, H. O., *see* BALL, K. P., and HUGHES, H. O., 296
HUGHES, K. E. A.: Spleen, calcified cyst of, 635
HUGHES, W. H., appointed Reader in Bacteriology, St. Mary's Hospital Medical School, 1479
HUGHES, William: Hormones and rheumatism, 1527
Hughlings Jackson Lecture, 1349
HULSE, H., *see* COPPOCK, J. B. M., HULSE, H., and URIE, A., 597
Hume, C. W.: *How to Befriend Laboratory Animals*, 1518 (A)
Hume, Edward H.: *Doctors East, Doctors West*, 1276
Humidity, effect on rheumatic disorders, 1305
— in deep mines, psychological effects of, 592
Humphrey, Leslie Alfred, obituary of, 1478, 1534
Hungary, tuberculosis services in, 1136
Hunner's ulcer of bladder, treatment of, 609
Hunter, Donald, *see* Hutchison, Sir Robert, and Hunter, Donald, 518
Hunter, John, and John Banks Hunter; exhibition of new documents, 868; correction, 1064
Hunterian Lectures, 191; correction, 346
Hunterian Oration, 663
Hunterian Society: Lecture programme, 1949–50, 884
— New Hunter documents exhibited, 868; correction, 1064
Husband-Clutton, Frank, obituary of, 1477
HUSSAIN, K. K.: Chronic progressive external ophthalmoplegia, 1392
Hutchison, Sir Robert, and Hunter, Donald: *Clinical Methods*, 12th ed., 518
Hyaluronidase and bee-*sting* sensitivity, 1474
Hydatid cyst associated with cirrhosis (C. P. Silver), 423
Hydatidiform mole, diagnosis by pregnanediol assay, 833
Hydrocephalus following streptomycin therapy of tuberculous meningitis (S. N. De), 214 (O)
Hydrosalpinx, bilateral, with torsion of both tubes (Richard E. Shaw), 421
Hydrotherapy, assistants, register of, 715
— specific value of, 1246
17-Hydroxy-11-dehydrocorticosterone, *see* Cortisone
Hygiene (J. R. Currie and A. G. Mearns), 3rd ed., 424
Hygiene in the public house, 760
Hyoscine for sea-sickness, 885
Hypernephroma, extrarenal (Frank Forty), 850
Hyperpyrexia complicating infantile eczema (E. Maclean Poulton), 1026
— rheumatic pericarditis with (Douglass W. Taylor), 59
Hypersensitivity reactions, pathology of (Hilding Berglstrand and others), 169
Hypertension and functional menorrhagia, 111
— and pregnancy, 494
— *Arterial Hypertension* (David Ayman), 371
— caesarean section in, 148
— electrocardiographic investigation of 264 cases (Poul Bechgaard), 1089 (O)
— essential, in pregnancy, 148; correspondence, 335, 486, 650, 758, 816, 871
— — shunts in, 548
— Kempner rice diet; Ministry of Food arrangement, 1482
— low-salt diet in treatment of (H. O. Bang, P. Bechgaard, and A. Levin Nielsen), 1203 (O)
— malignant, 1102 (A)
— portal, 273 (A); correspondence, 438
— prefrontal leucotomy in (R. W. Tibbetts), 1452 (O)
Hyperthyroidism, Bram's test, 241
Hypnosis in treatment, 653, 756, 816, 874, 1176
— in treatment of pain, 413, 427 (L), 430
— *Medical Hypnosis*, Vol. 1 (Lewis R. Wolberg), 914
Hypochlorhydria in sprue, 771
Hypoglycaemia and cerebral lesions, 38
— diagnosis and treatment of (Wilfrid Oakley), 1403
Hypopituitarism, 1109
Hypothalamus, lesions of, obesity after, 951
Hypothyroidism, psychosis due to, 555
Hysteria, prognosis in, 33

I

Icterus neonatorum, *see* Erythroblastosis foetalis
Ileo-ileal intussusception, gangrenous (J. A. Kerr), 580; correspondence, 933
Ileus, spastic, 1267, 1281
Iliac fossa, right, pain in (A. Fulleron and others), 171; gynaecological aspects (Kenneth Bowes and others), 171
ILLINGWORTH, R. S.: Common difficulties in infant feeding, 1077 (O); correspondence, 1297
— and DOXIADIS, S. A.: Significance of convulsions in infancy, 547
Immunity in early life (symposium; Society of Medical Officers of Health), 332
Immunization, dangers of, after an attack of diphtheria, 767
— staphylococcal toxaemia following, 750
Imperial Cancer Research Fund Lecture, 1487
Incontinence, stress, in disseminated sclerosis, 438
— — Marlius bulbo-cavernosus operation for (Wilfred Shaw), 1261 (O)
— — treatment of, 99, 387, 438, 600
Incontinentia pigmenti, 231
India, B.C.G. vaccination, 154
— teaching of pharmacology in, 233
— tuberculosis in, 152
Individuality in medicine; Harveian Oration (Geoffrey Marshall), 941 (O)
Industrial fluorosis, 1163 (A)
— health, diploma in, 541
— — services, inquiry into, 294
— medicine: Tuberculosis as industrial disease, 683
Industry and psychology; discussion at British Association meeting, 647
— Return to work of elderly male hospital in-patients (John Pemberton and Jean C. Smith), 306 (O)
— tuberculosis in, 31, 230, 334
INFANTS: *see also* CHILDREN
Breast-feeding, post-war incidence of (F. H. M. Dummer), 14 (O); correspondence, 388
Convulsions, significance of (P. W. Nathan and P. M. Ransford), 421 (O); correspondence, 547, 598, 1115
— relation to epilepsy, 421, 547, 598, 1115
Diagnostic Tests for Infants and Children (H. Behrendt), 637
Diarrhoea and vomiting; clinical and bacteriological investigation (Joan Taylor, B. W. Powell, Joyce Wright), 117 (O); leading article, 141, 473; correspondence, 283, 386, 1176
— — — streptomycin in (A. Heitzel, G. Martyn, and L. Apter), 454 (O); annotation, 478; correspondence, 652
Feeding, common difficulties in (R. S. Illingworth), 1077 (O); correspondence, 1297
— Management of premature baby, 1104
Height and weight norms of, 1122
Intestinal organisms causing septicaemia and meningitis, effect of streptomycin on (Robert Debré and Pierre Mozziconacci), 451 (O); annotation, 479
New neonatal syndrome (W. G. Mills), 464 (O); correspondence, 756, 871
Newborn: Incidence of infections in two maternity units (Janet D. Rouse), 1144 (O); leading article, 1219
— Variations in bacteriology of throat and rectum (Allan M. McFarlan, P. B. Crone, and G. H. Tee), 1140 (O); leading article, 1219
Premature, domiciliary care of (F. J. W. Miller and others), 87
— management of (Alan Moncrieff), 1104
Infection, dust-borne, control of, 1539
— from crockery, 466
— in the nursery, 1219 (L)
— *Klinische Infektionslehre*, 2nd ed. (Felix O. Höring), 1396
Infectious-disease certificates (parliamentary note), 339
Infectious diseases, insurance against, 159
— — weekly returns, 36, 163, 166, 238, 292, 342, 394, 444, 491 (correction, 551), 551, 606, 658, 714, 764, 852, 936, 996, 1059, 1123, 1186, 1242, 1302, 1362, 1422, 1481, 1538
Infertility: Family Planning Association conference on, 809
— Male subfertility; report of 3,182 cases (H. A. Davidson), 1328 (O)
— physiological, 397
Influenza, diagnosis and treatment, recent developments in (C. H. Andrewes and others), 93
— virus, electron-microscopic appearance of, 1249
INGRAM, H. V.: Scleromalacia perforans, 92
INGRAM, John T.: Chilblains, 1284; correspondence, 1417, 1473
Injection, intravenous, concentrated solutions for, 1230
Insanity and murder; adequacy of M'Naghten rules, 455, 711, 818, 1050, 1297
— in the criminal law of Malta (Paul Cassar) (medico-legal note), 1182
Insecticides for aircraft, 1394
— in mosquito control, 595
INSLEY, John L.: Splint to control dorsal subluxation of proximal interphalangeal joints of fingers, 472
Institute for the Scientific Treatment of Delinquency: University extension lectures, 493; 11th annual general meeting, 1349
— of Cardiology, 530
— of Child Health, 530; 3rd annual report, 319
— of Dental Surgery, 531
— of Dermatology, 530
— of Diseases of the Chest, 530; description of, 977; opening of, 1039
— of Laryngology and Otology, 530
— of Medical Laboratory Technology, 1243
— of Neurology, 531
— of Obstetrics and Gynaecology, 531
— of Ophthalmology, 531
— of Orthopaedics, 531
— of Psychiatry, 531, 542; appointments, 935
— of Psycho-Analysis, 542
— of Urology, 531
— of Venereal Disease Technicians, inaugural conference, 395
Instruments, medical and surgical, *see* Preparations and Appliances
Insulin, chemistry of, 225 (A)
— hypoglycaemia following administration of, cerebral effects, 38
— in diabetes, indications and dosage, 1346
— requirements, 922 (A)

Insurance: Sickness insurance for women, 1482
Intellectual deterioration in myxoedema, experimental study of (Sidney Crown), 684 (O)
Intelligence: Trend of national intelligence, 969 (L)
International book exhibition, 96
— Conference on Audiology, 332
— Congress of Biochemistry: First meeting, Cambridge, 590
— — of Catholic Doctors, 188
— — of Electroencephalography, 446
— — of Haematology, 1124
— — of Military Medicine and Pharmacy, 295
— — of Otolaryngology, 4th meeting, London, 240, 276; Edinburgh visit, 329
— — on Rheumatic Diseases: Progress in treatment of rheumatic disorders, 154, 166
— — of Surgery, New Orleans, 1406
— Neurological Congress, 4th meeting, Paris, 697
— Pharmaceutical Federation, 445
— Scientific Film Association, 1043
— Society of Surgery, 13th congress, 240
— Union of Nutritional Sciences, 396
— Veterinary Congress, 14th, 376 (A); Animal diseases communicable to man, 433
Intervertebral disk, lumbar, lesions of, 1524
— — prolapse of, after lumbar puncture (J. N. Wilson), 1334
Intestinal organisms causing septicaemia and meningitis in infants, effect of streptomycin on (Robert Debré and Pierre Mozziconacci), 451 (O); annotation, 479
Intestines, distension of, 1246
— haemorrhage, aetiology, 241
— intussusception, in childhood; successful treatment of two cases in childhood (D. J. Conway and R. L. G. Dawson), 1153 (O); correspondence, 1355
— small, volvulus of (W. Weatherston Wilson), 636
— strangulation, internal; two rare cases (F. D. Hindmarsh), 1274
Intracranial Tumors (Percival Bailey), 2nd ed., 475
Intracranial suppuration, 979
Intussusception, gangrenous, successful treatment of two cases in childhood (D. J. Conway and R. L. G. Dawson), 1153 (O); correspondence, 1355
— ileo-ileal, gangrenous (J. A. Kerr), 580; correspondence, 983
Invalid Kitchens of London, 1344
Invalids, home feeding of, 1344 (A)
— milk allowance for, 997
— special diets for, Ministry of Food arrangements for, 37
Iontophoresis in peripheral vascular disease (H. S. Pemberton and D. C. Watson), 633 (O)
Ireland, Northern: Registrar-General's quarterly returns (epidemiological note), 394
Iron therapy: Fatal poisoning of infant by anti-anaemia pills (J. H. Prain), 1019 (O); annotation, 1034; correspondence, 1298, 1356
— — intravenous, 189

Royal Institute of Philosophy, *programme for* 1949–50, 822

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE:
Bengué Memorial Lecture, 396
Harben Medal presented to Lord Boyd-Orr, 294
Need for smoke abatement; address by Sir George Elliston, 1348
Presidential Address (Walter Elliot), 297 (O), annotation, 327; correspondence, 489, 706, 869, 1047; parliamentary note, 1535
Smith award to M. T. Morgan, 294

Royal London Homoeopathic Hospital, centenary of, 993
Royal Medical Benevolent Fund, 384, 1044, 1294; annual report, 591
Royal Medical Society of Edinburgh: Lecture programme, 1949–50, 884.

Royal Medico-Psychological Association:
Diploma in psychological medicine, 395
Presidential address on mental hospital organization (*J. Ivison Russell*), 435

Royal Microscopical Society: Cine-micrographic film library, 754
Royal Navy, *see* Armed Forces
Royal Photographic Society: Exhibitions, 446, 883
Royal Society: Awards, 1164 (A); elections, 1363

ROYAL SOCIETY OF MEDICINE:
Honorary Fellows, new, 67
Hughlings Jackson Lecture: Encephalitis and encephalomyelitis in man (*J. G. Greenfield*), 1349
Section of Epidemiology and State Medicine: Discussion on mechanism of antibody production, 1293
Preventive health services, 1041
Section of Experimental Medicine: Some aspects of undernutrition, 1526
Section of Medicine: Rheumatic fever, management of, 1042
Pruritus of sc... OF MEDICINE *(continued)*:
— of scrotur *Neurology*: Presidential address on
— vulvae (Cranial suppuration (Julian Taylor), 979
spondement of the gliomata, 1408
— — ps... *of Obstetrics and Gynaecology*: Whither ... ...ntenatal care? 1108
...ion of Ophthalmology: Progress in ophthalmology, 926
Section of Otology: Medical treatment of aural vertigo, 1409
Section of Physical Medicine: Cortisone in rheumatoid arthritis, 1040; correction, 1190
Section of Psychiatry: Aspects of leucotomy, 700, 1303
Music in psychological medicine, 1469
United Services Section: Discussion on future of medical officers in the Forces, 94

ROYDE, C. A.: Treatment of infantile gastro-enteritis, 486
Rubella *in pregnancy*, effect on foetus, 1164 (A)

RUSSELL, E. N.: Pylorospasm in adult, complicated by uraemia, 18
RUSSELL, H. S.: Gravitational ulcers of the leg, 598
— Jelly-fish and weever-fish, 1190
— Use and abuse of vitamins, 1413
— Chilblains, 1473
RUSSELL J. Ivison: Mental hospital organization; presidential address to Royal Medico-Psychological Association, 435
RUSSELL, Sir John: Presidential address to British Association, 585 (L)
Russell viper venom method for prothrombin estimation, 1493
Russia, *see* U.S.S.R.
RUST, S. M., and FOSBERY, F. W. A.: *Prevention* of sea-sickness, 98
RUTHERFORD, N. J. C.: Jealousy in a child, 1064
RYAN, Vincent: Tuberculosis and other conditions in childhood, 91
Rye flour for allergic patients, 187
RYLE, John A.: *Man and the machine*, 176

S

SAALER, B. C. Tuberculosis in Scotland, 489
St. Andrews, *see* Universities, St. Andrews
St. Bartholomew's Hospital: *Round the Fountain*, 1456
Wessex Rahere Club, 1061
St. Giles Home for lepers, Chelmsford (parliamentary note), 1361
St. John of Jerusalem, Order of: Promotions and appointments, 281
St. Luke's Day, 873
St. Mary's Hospital Medical School: Appointments, 340, 605, 1479
St. Thomas's Hospital: St. Thomas's Parish Vestry records and a body-snatching incident (Laurence Dopson), 69
St. Thomas's Hospital Medical School: Appointments, 1479
SAKOSCHANSKY, E.: Rheumatoid arthritis and herpes zoster, 984
Salford, typhoid fever in (epidemiological note), 1186
Salicylanilide in ringworm of scalp, 626, 875
Salicylates in rheumatic fever, 33; (G. Watkinson and others), 167
Salicyl-sulphonic acid test for albumin in urine, 1306, 1540
Salivary gland enlargement (Mikulicz's syndrome) (Alan J. Hird), 416 (O); correction, 610
Salivation, excessive, treatment of, 495
Salkeld, Charles, obituary of, 234
Salmonella bovis morbificans, food-poisoning due to, 264
— *enteritidis* septicaemia with lung abscess (*I. McLean Baird and L. Capper*), 316 (O)
— infections in infants causing septicaemia and *meningitis, streptomycin in*, 451
— *paratyphi B*, effect of chloramphenicol on, 1504
— — isolation from cat faeces, 1256
— *typhi* O agglutinin reaction, 1366
— *typhi-murium* infection, hospital outbreak due to duck eggs (Lawrence P. Garrod and M. B. McIlroy), 1259 (A); annotation, 1281; correspondence, 1416
— — subacute bacterial endocarditis due to (*J. de Sa'el*), 1155
Salmonellae, animal sources of, 1254, 1259, 1281 (A), 1416
— isolation from dogs, cats, and pigeons (*J. C. Cruickshank and H. Williams Smith*), 1254 (O); annotation, 1281
Salt: Low-salt diet in treatment of hypertension and hypertensive heart disease (*H. O. Bang, P. Bechgaard, and A. Levin Nielsen*), 1203 (O)
SALZMANN, K. D.: Ergotamine and pregnancy, 346

NADE, P. S.: Transfusion in domiciliary midwifery, 756
nderson-Wells Prize award, 187, 1361
NDIFORD, B. R.: Poliomyelitis vaccination, 1114
NDLER, B.: Dyspareunia, 190
PIER, N. V.: Treatment of erysipeloid with penicillin, 1175
arcoma, *see* Cancer
armentogenin, production of "cortisone" from, 481
AVAGE, O.: Cortisone in rheumatoid arthritis, 1040
— *see* Copeman, W. S. C., and Savage, O., 1110
